

bq25896 I²C 控制型单节电池 3A 快速充电器，采用 MaxCharge™ 技术，支持高输入电压 和可调电压 USB On-the-Go (OTG) 升压模式

1 特性

- 高效率 3A 1.5MHz 开关模式降压充电
 - 92.5% 的充电效率（充电电流为 2A）和 90.5% 的充电效率（充电电流为 3A）
 - 针对高电压输入 (9V/12V) 进行优化
 - 低功耗 PFM 模式，适合轻载运行
- USB On-the-Go (OTG) 以及 4.5V 至 5.5V 的可调输出电压范围
 - 可选 500KHz/1.5MHz 升压转换器，输出电流高达 2A
 - 5V/1A 输出时的升压效率为 93%
 - 精确的断续模式过流保护
 - 支持低至 2.5V 的电池
 - 针对轻载效率支持仅 PWM 或 PFM/PWM 控制
- 单个输入，支持 USB 输入和可调高电压适配器
 - 支持 3.9V 至 14V 输入电压范围
 - 输入电流限制（100mA 至 3.25A，分辨率为 50mA），支持 USB2.0、USB3.0 标准和高电压适配器
 - 通过输入电压限制（最高 14V）实现最大功率跟踪，适用于各类适配器
- 输入电流优化器 (ICO)，无需过载适配器即可最大限度提高输入功率
- 充电器输出与电池终端间的电阻补偿 (IRCOMP)
- 借助 11mΩ 电池放电 MOSFET 实现最高电池放电效率，放电电流高达 9A
- 集成 ADC，用于系统监视（电压、温度和充电电流）
- 窄 VDC (NVDC) 电源路径管理
 - 无需电池或使用深度放电的电池即可瞬时接通
 - 电池充电模式下实现理想的二极管运行
- BATFET 控制，支持运输模式、唤醒和完全系统复位
- 灵活的自主和 I²C 模式，可实现最优系统性能
- 高集成度，包括所有 MOSFET、电流检测和环路补偿
- 12μA 低电池泄漏电流，支持运输模式
- 高精度
 - ±0.5% 充电电压调节

- ±5% 充电电流调节
- ±7.5% 输入电流调节
- 安全
 - 用于充电模式和升压模式的电池温度感测
 - 热调节和热关断

2 应用

- 智能手机
- 平板电脑
- 便携式网络设备

3 说明

bq25896 是一款适用于单节锂离子电池和锂聚合物电池的高度集成型 3A 开关模式电池充电管理和系统电源路径管理器件。此类器件支持高输入电压快速充电。低阻抗电源路径对开关模式运行效率进行了优化、缩短了电池充电时间并延长了放电阶段的电池使用寿命。具有充电和系统设置的 I²C 串行接口使得此器件成为一个真正的灵活解决方案。

器件信息⁽¹⁾

器件型号	封装	封装尺寸（标称值）
bq25896	WQFN (24)	4.00mm x 4.00mm

4 修订历史记录

Changes from Revision B (October 2016) to Revision C	Page
• Added sentence to the Battery Monitor section "In battery only mode, .."	24
• Changed the Type values of Bit 7 in 表 26 From: R To: R/W	48
Changes from Revision A (September 2015) to Revision B	Page
• 首次发布完整的产品说明书	1
Changes from Original (July 2015) to Revision A	Page
• 将数据表的状态从“预览”更改为“生产数据”	1
• 将简化原理图中的 OTG 从 5V/1.5A 更改为 5V/2A	1

5 说明（续）

bq25896 是一款适用于单节锂离子电池和锂聚合物电池的高度集成型 **3A** 开关模式电池充电管理和系统电源路径管理器件。该器件支持高输入电压快速充电，适用于各类智能手机、平板电脑和便携式设备。其低阻抗电源路径对开关模式运行效率进行了优化、缩短了电池充电时间并延长了放电阶段的电池使用寿命。该器件还集成了输入电流优化器 (**ICO**) 和电阻补偿 (**IRCOMP**)，从而为电池提供最大充电功率。该解决方案在系统和电池之间高度集成输入反向阻断 **FET** (**RBFET**, **Q1**)、高侧开关 **FET** (**HSFET**, **Q2**)、低侧开关 **FET** (**LSFET**, **Q3**) 以及电池 **FET** (**BATFET**, **Q4**)。它还集成了自举二极管以进行高侧栅极驱动和电池监视，从而简化系统设计。具有充电和系统设置的 **I²C** 串行接口使得此器件成为一个真正的灵活解决方案。

该器件支持多种输入源，并且从系统检测电路（如 **USB PHY** 器件）中获取结果。输入电流和电压调节选择符合 **USB 2.0** 和 **USB 3.0** 电源规范。此外，输入电流优化器 (**ICO**) 还能够检测输入源未发生过载时的最大功率点。该器件还具有高达 **2A** 的限流能力，能够为 **VBUS** 提供 **5V** (**4.5V-5.5V** 可调节) 电压，符合 **USB On-the-Go (OTG)** 运行功率额定值规范。

电源路径管理将系统电压调节至稍高于电池电压的水平，但是不会下降至 **3.5V** 最小系统电压（可编程）以下。借助于这个特性，即使在电池电量完全耗尽或者电池被拆除时，系统也能保持运行。当达到输入电流限值或电压限值时，电源路径管理自动将充电电流减少为 **0**。随着系统负载持续增加，电源路径将使电池放电，直到满足系统电源需求。这种 **补充模式** 工作方式可防止输入源发生过载。

此器件在无需软件控制情况下启动并完成一个充电周期。它自动检测电池电压并通过三个阶段为电池充电：预充电、恒定电流和恒定电压。在充电周期的末尾，当充电电流低于在恒定电压阶段中预设定的限值时，充电器自动终止。当整个电池下降到低于再充电阈值时，充电器将自动启动另外一个充电周期。

此充电器提供针对电池充电和系统运行情况的多种安全特性，其中包括电池负温度系数热敏电阻监视、充电安全计时器和过压/过流保护。当结温超过 **120°C**（可编程）时，热调节会减小充电电流。**STAT** 输出报告充电状态和任何故障状况。**PG** 输出指示电源是否正常。当故障发生时，**INT** 会立即通知主机。

该器件还提供了一个 **7** 位模数转换器 (**ADC**)，用于监视充电电流和输入/电池/系统 (**VBUS**、**BAT**、**SYS**、**TS**) 电压。**QON** 引脚提供 **BATFET** 使能/复位控制，以使器件退出低功耗出厂模式或完全系统复位功能。

该器件系列采用 **24** 引脚 **4mm x 4mm² x 0.75mm** 薄型 **WQFN** 封装。

6 Device Comparison Table

	bq25896
I ² C Address	6BH (1101011B + R/W)
Charge Mode Frequency	1.5 MHz
Boost Mode Frequency	1.5 MHz (default) / 500 KHz
USB Detection	PSEL/OTG
VBUS Overvoltage	14 V
REGN LDO	5 V
Default Adapter Current Limit	3.25 A
Default Battery Charge Voltage	4.208 V
Maximum Charge Current	3.008A
Default Charge Current	2.048 A
Default Pre-charge Current	128 mA
Maximum Pre-charge Current	1.024A
Maximum Boost Mode Output Current	2A
Charging Temperature Profile	JEITA
Pin 24	NC
Status Output	STAT, PG

7 Pin Configuration and Functions

Pin Functions

PIN		TYPE ⁽¹⁾	DESCRIPTION
NAME	NO.		
VBUS	1	P	Charger Input Voltage. The internal n-channel reverse block MOSFET (RBFET) is connected between VBUS and PMID with VBUS on source. Place a 1-μF ceramic capacitor from VBUS to PGND and place it as close as possible to IC.
PSEL	2	DI	Power source selection input. High indicates a USB host source and Low indicates an adapter source.
$\overline{\text{PG}}$	3	DO	Open drain active low power good indicator. Connect to the pull up rail via 10-kΩ resistor. LOW indicates a good input source if the input voltage is within $V_{\text{VBUS_OP}}$, above SLEEP mode threshold (V_{SLEEPZ}), and current limit is above I_{BATSRC} (30 mA).
STAT	4	DO	Open drain charge status output to indicate various charger operation. Connect to the pull up rail via 10-kΩ resistor. LOW indicates charge in progress. HIGH indicates charge complete or charge disabled. When any fault condition occurs, STAT pin blinks in 1 Hz. The STAT pin function can be disabled when STAT_DIS bit is set.
SCL	5	DI	I ² C Interface clock. Connect SCL to the logic rail through a 10-kΩ resistor.
SDA	6	DIO	I ² C Interface data. Connect SDA to the logic rail through a 10-kΩ resistor.
INT	7	DO	Open-drain Interrupt Output. Connect the INT to a logic rail via 10-kΩ resistor. The INT pin sends active low, 256-μs pulse to host to report charger device status and fault.
OTG	8	DI	Boost mode enable pin. The boost mode is activated when OTG_CONFIG =1, OTG pin is high, and no input source is detected at VBUS
$\overline{\text{CE}}$	9	DI	Active low Charge Enable pin. Battery charging is enabled when CHG_CONFIG = 1 and $\overline{\text{CE}}$ pin = Low. $\overline{\text{CE}}$ pin must be pulled High or Low.
ILIM	10	AI	Input current limit Input. ILIM pin sets the maximum input current and can be used to monitor input current ILIM pin sets the maximum input current limit by regulating the ILIM voltage at 0.8 V. A resistor is connected from ILIM pin to ground to set the maximum limit as $I_{\text{INMAX}} = K_{\text{ILIM}}/R_{\text{ILIM}}$. The actual input current limit is the lower limit set by ILIM pin (when EN_ILIM bit is high) or IILNLM register bits. Input current limit of less than 500 mA is not support on ILIM pin. ILIM pin can also be used to monitor input current when the voltage is below 0.8V. The input current is proportional to the voltage on ILIM pin and can be calculated by $I_{\text{IN}} = (K_{\text{ILIM}} \times V_{\text{ILIM}}) / (R_{\text{ILIM}} \times 0.8)$ The ILIM pin function can be disabled when EN_ILIM bit is 0.

(1) DI (Digital Input), DO (Digital Output), DIO (Digital Input/Output), AI (Analog Input), AO (Analog Output), AIO (Analog Input/Output)

Pin Functions (continued)

PIN		TYPE ⁽¹⁾	DESCRIPTION
NAME	NO.		
TS	11	AI	Temperature qualification voltage input. Connect a negative temperature coefficient thermistor. Program temperature window with a resistor divider from REGN to TS to GND. Charge suspends when either TS pin is out of range. Recommend 103AT-2 thermistor.
$\overline{\text{QON}}$	12	DI	BATFET enable/reset control input. When BATFET is in ship mode, a logic low of t_{SHIPMODE} (typical 1sec) duration turns on BATFET to exit shipping mode. . When VBUS is not plugged-in, a logic low of $t_{\text{QON_RST}}$ (typical 18sec) duration resets SYS (system power) by turning BATFET off for $t_{\text{BATFET_RST}}$ (typical 0.3sec) and then re-enable BATFET to provide full system power reset. The pin contains an internal pull-up to maintain default high logic
BAT	13, 14	P	Battery connection point to the positive terminal of the battery pack. The internal BATFET is connected between BAT and SYS. Connect a 10uF closely to the BAT pin.
SYS	15,16	P	System connection point. The internal BATFET is connected between BAT and SYS. When the battery falls below the minimum system voltage, switch-mode converter keeps SYS above the minimum system voltage. Connect a 20uF closely to the SYS pin.
PGND	17,18	P	Power ground connection for high-current power converter node. Internally, PGND is connected to the source of the n-channel LSFET. On PCB layout, connect directly to ground connection of input and output capacitors of the charger. A single point connection is recommended between power PGND and the analog GND near the IC PGND pin.
SW	19,20	P	Switching node connecting to output inductor. Internally SW is connected to the source of the n-channel HSFET and the drain of the n-channel LSFET. Connect the 0.047μF bootstrap capacitor from SW to BTST.
BTST	21	P	PWM high side driver positive supply. Internally, the BTST is connected to the anode of the boost-strap diode. Connect the 0.047 μF bootstrap capacitor from SW to BTST.
REGN	22	P	PWM low side driver positive supply output. Internally, REGN is connected to the cathode of the boost-strap diode. Connect a 4.7 μF (10 V rating) ceramic capacitor from REGN to analog GND. The capacitor should be placed close to the IC. REGN also serves as bias rail of TS pin.
PMID	23	DO	Connected to the drain of the reverse blocking MOSFET (RBFET) and the drain of HSFET. Given the total input capacitance, put 1μF on VBUS to PGND, and the rest capacitance on PMID to PGND.
NC	24		No Connect
PowerPAD™		P	Exposed pad beneath the IC for heat dissipation. Always solder PowerPAD Pad to the board, and have vias on the PowerPAD plane star-connecting to PGND and ground plane for high-current power converter.

8 Specifications

8.1 Absolute Maximum Ratings⁽¹⁾

over operating free-air temperature range (unless otherwise noted)

		MIN	MAX	VALUE
Voltage range (with respect to GND)	V _{BUS} (converter not switching)	–2	22	V
	P _{MID} (converter not switching)	–0.3	22	V
	STAT	–0.3	20	V
	P _G	–0.3	7	V
	BTST	–0.3	20	V
	SW	–2	16	V
	SW (peak for 10 ns duration)	–3	16	V
	BAT, SYS (converter not switching)	–0.3	6	V
	SDA, SCL, INT, OTG, REGN, TS, $\overline{\text{CE}}$, $\overline{\text{QON}}$	–0.3	7	V
	PSEL	–0.3	7	V
	BTST TO SW	–0.3	7	V
	PGND to GND	–0.3	0.3	V
	ILIM	–0.3	5	V
Output sink current	INT, STAT		6	mA
	P _G		6	mA
Junction temperature		–40	150	°C
Storage temperature range, T _{stg}		–65	150	°C

- (1) Stresses beyond those listed under absolute maximum ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under recommended operating conditions is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability. All voltage values are with respect to the network ground terminal unless otherwise noted.

8.2 ESD Ratings

		VALUE	UNIT
V _{ESD} Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
	Charged device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±250	V

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

8.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V _{IN}	Input voltage	3.9		14 ⁽¹⁾	V
I _{IN}	Input current (VBUS)			3.25	A
I _{SYS}	Output current (SW)			5	A
V _{BAT}	Battery voltage			4.608	V
I _{BAT}	Fast charging current			3	A
	Discharging current with internal MOSFET			Up to 6 (continuous)	A
				9 (peak) (Up to 1 sec duration)	A
T _A	Operating free-air temperature range	–40		85	°C

- (1) The inherent switching noise voltage spikes should not exceed the absolute maximum rating on either the BTST or SW pins. A tight layout minimizes switching noise.

8.4 Thermal Information

THERMAL METRIC ⁽¹⁾		bq25896	UNIT
		RTW (WQFN)	
		24-PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	31.8	°C/W
$R_{\theta JC(op)}$	Junction-to-case (top) thermal resistance	27.9	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	8.7	°C/W
Ψ_{JT}	Junction-to-top characterization parameter	0.3	°C/W
Ψ_{JB}	Junction-to-board characterization parameter	8.7	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	2.0	°C/W

(1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

8.5 Electrical Characteristics

$V_{VBUS_UVLOZ} < V_{VBUS} < V_{ACOV}$ and $V_{VBUS} > V_{BAT} + V_{SLEEP}$, $T_J = -40^{\circ}\text{C}$ to $+125^{\circ}\text{C}$ and $T_J = 25^{\circ}\text{C}$ for typical values (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
QUIESCENT CURRENTS					
I_{BAT}	Battery discharge current (BAT, SW, SYS) in buck mode	$V_{BAT} = 4.2\text{ V}$, $V_{VBUS} < V_{(UVLO)}$, leakage between BAT and VBUS		5	μA
		High-Z mode, no VBUS, BATFET disabled (REG09[5]=1), battery monitor disabled, $T_J < 85^{\circ}\text{C}$	12	23	μA
		High-Z mode, no VBUS, BATFET enabled (REG09[5]=0), battery monitor disabled, $T_J < 85^{\circ}\text{C}$	32	60	μA
$I_{(VBUS_HIZ)}$	Input supply current (VBUS) in buck mode when High-Z mode is enabled	$V_{VBUS} = 5\text{ V}$, High-Z mode, no battery, battery monitor disabled	15	35	μA
		$V_{VBUS} = 12\text{ V}$, High-Z mode, no battery, battery monitor disabled	25	50	μA
$I_{(VBUS)}$	Input supply current (V_{BUS}) in buck mode	$V_{BUS} > V_{(UVLO)}$, $V_{BUS} > V_{BAT}$, converter not switching	1.5	3	mA
		$V_{BUS} > V_{(UVLO)}$, $V_{BUS} > V_{BAT}$, converter switching, $V_{BAT} = 3.2\text{ V}$, $I_{SYS} = 0\text{ A}$	3		mA
		$V_{BUS} > V_{(UVLO)}$, $V_{BUS} > V_{BAT}$, converter switching, $V_{BAT} = 3.8\text{ V}$, $I_{SYS} = 0\text{ A}$	3		mA
$I_{(BOOST)}$	Battery discharge current in boost mode	$V_{BAT} = 4.2\text{ V}$, boost mode, $I_{(VBUS)} = 0\text{ A}$, converter switching	5		mA
VBUS/BAT POWER UP					
$V_{(VBUS_OP)}$	VBUS operating range		3.9	14	V
$V_{(VBUS_UVLOZ)}$	VBUS for active I ² C, no battery		3.6		V
$V_{(SLEEP)}$	Sleep mode falling threshold		25	65	mV
$V_{(SLEEPZ)}$	Sleep mode rising threshold		130	250	mV
$V_{(ACOV)}$	VBUS over-voltage rising threshold		14	14.6	V
	VBUS over-voltage falling threshold		13.5	14	V
$V_{BAT(UVLOZ)}$	Battery for active I ² C, no VBUS		2.3		V
$V_{BAT(DPL)}$	Battery depletion falling threshold		2.15	2.5	V
$V_{BAT(DPLZ)}$	Battery depletion rising threshold		2.35	2.7	V
$V_{(VBUSMIN)}$	Bad adapter detection threshold		3.8		V
$I_{(BADSRC)}$	Bad adapter detection current source		30		mA
POWER-PATH MANAGEMENT					
V_{SYS}	Typical system regulation voltage	$I_{(SYS)} = 0\text{ A}$, $V_{BAT} > V_{SYS(MIN)}$, BATFET Disabled (REG09[5]=1)		$V_{BAT} + 50\text{ mV}$	V
		$I_{(SYS)} = 0\text{ A}$, $V_{BAT} < V_{SYS(MIN)}$, BATFET Disabled (REG09[5]=1)		$V_{SYS(MIN)} + 150\text{ mV}$	V
$V_{SYS(MIN)}$	Minimum DC system voltage output	$V_{BAT} < V_{SYS(MIN)}$, $SYS_MIN = 3.5\text{ V}$ (REG03[3:1]=101), $I_{SYS} = 0\text{ A}$	3.50	3.65	V
$V_{SYS(MAX)}$	Maximum DC system voltage output	$V_{BAT} = 4.35\text{ V}$, $SYS_MIN = 3.5\text{ V}$ (REG03[3:1]=101), $I_{SYS} = 0\text{ A}$	4.40	4.42	V
$R_{ON(RBFET)}$	Top reverse blocking MOSFET(RBFET) on-resistance between VBUS and PMID	$T_J = -40^{\circ}\text{C}$ to $+85^{\circ}\text{C}$	27	38	$\text{m}\Omega$
		$T_J = -40^{\circ}\text{C}$ to $+125^{\circ}\text{C}$	27	44	$\text{m}\Omega$

Electrical Characteristics (continued)

$V_{VBUS_UVLOZ} < V_{VBUS} < V_{ACOV}$ and $V_{VBUS} > V_{BAT} + V_{SLEEP}$, $T_J = -40^{\circ}\text{C}$ to $+125^{\circ}\text{C}$ and $T_J = 25^{\circ}\text{C}$ for typical values (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT

9 Detailed Description

The device is a highly integrated 5-A switch-mode battery charger for single cell Li-Ion and Li-polymer battery. It is highly integrated with the input reverse-blocking FET (RBFET, Q1), high-side switching FET (HSFET, Q2), low-side switching FET (LSFET, Q3), and battery FET (BATFET, Q4). The device also integrates the bootstrap diode for the high-side gate drive.

9.1 Functional Block Diagram

Copyright © 2016, Texas Instruments Incorporated

9.2 Feature Description

9.2.1 Device Power-On-Reset (POR)

The internal bias circuits are powered from the higher voltage of VBUS and BAT. When VBUS rises above V_{VBUS_UVLOZ} or BAT rises above V_{BAT_UVLOZ} , the sleep comparator, battery depletion comparator and BATFET driver are active. I²C interface is ready for communication and all the registers are reset to default value. The host can access all the registers after POR.

9.2.2 Device Power Up from Battery without Input Source

If only battery is present and the voltage is above depletion threshold (V_{BAT_DPLZ}), the BATFET turns on and connects battery to system. The REGN LDO stays off to minimize the quiescent current. The low $R_{DS(ON)}$ of BATFET and the low quiescent current on BAT minimize the conduction loss and maximize the battery run time. The device always monitors the discharge current through BATFET (*Supplement Mode*). When the system is overloaded or shorted ($IBAT > I_{BATFET_OCP}$), the device turns off BATFET immediately and set BATFET_DIS bit to indicate BATFET is disabled until the input source plugs in again or one of the methods describe in *BATFET Enable (Exit Shipping Mode)* is applied to re-enable BATFET.

9.2.3 Device Power Up from Input Source

When an input source is plugged in, the device checks the input source voltage to turn on REGN LDO and all the bias circuits. It detects and sets the input current limit before the buck converter is started when AUTO_DPDM_EN bit is set. The power up sequence from input source is as listed:

1. Power Up REGN LDO
2. Poor Source Qualification
3. *Input Source Type Detection* based on PSEL to set the default Input Current Limit (IINLIM) register and input source type
4. Input Voltage Limit Threshold Setting (VINDPM threshold)
5. Converter Power-up

9.2.3.1 Power Up REGN Regulation (LDO)

The REGN LDO supplies internal bias circuits as well as the HSFET and LSFET gate drive. The LDO also provides bias rail to TS external resistors. The pull-up rail of STAT and can be connected to REGN as well. The REGN is enabled when all the below conditions are valid.

1. VBUS above V_{VBUS_UVLOZ}
2. VBUS above $V_{BAT} + V_{SLEEPZ}$ in buck mode or VBUS below $V_{BAT} + V_{SLEEP}$ in boost mode
3. After 220 ms delay is completed

If one of the above conditions is not valid, the device is in high impedance mode (HIZ) with REGN LDO off. The device draws less than I_{VBUS_HIZ} from VBUS during HIZ state. The battery powers up the system when the device is in HIZ.

9.2.3.2 Poor Source Qualification

After REGN LDO powers up, the device checks the current capability of the input source. The input source has to meet the following requirements in order to start the buck converter.

1. VBUS voltage below V_{ACOV}
2. VBUS voltage above $V_{VBUSMIN}$ when pulling I_{BADSRC} (typical 30mA)

Once the input source passes all the conditions above, the status register bit VBUS_GD is set high and the INT pin is pulsed to signal to the host. If the device fails the poor source detection, it repeats poor source qualification every 2 seconds.

Feature Description (接下页)

9.2.3.3 Input Source Type Detection

After the VBUS_GD bit is set and REGN LDO is powered, the charger device runs *Input Source Type Detection* when AUTO_DPDM_EN bit is set.

After input source type detection, an INT pulse is asserted to the host. In addition, the following registers and pin are changed:

1. Input Current Limit (IINLIM) register is changed to set current limit
2. PG_STAT bit is set
3. $\overline{\text{PG}}$ pin goes low

The host can over-write IINLIM register to change the input current limit if needed. The charger input current is always limited by the lower of IINLIM register or ILIM pin at all-time regardless of Input Current Optimizer (ICO) is enable or disabled.

When AUTO_DPDM_EN is disabled, the *Input Source Type Detection* is bypassed. The Input Current Limit (IINLIM) register, VBUS_STAT, and SPD_STAT bits are unchanged from previous values.

9.2.3.3.1 PSEL Pins Set Input Current Limit

The device has PSEL interface for input current limit setting to interface with USB PHY. It directly takes the USB PHY device output to decide whether the input is USB host or charging port. To implement USB100 in the system, the host can enter HiZ mode by setting EN_HIZ bit after 2 min charging with 500 mA input current limit.

表 1. bq25896 Result

INPUT DETECTION	PSEL PIN	INPUT CURRENT LIMIT (IINLIM)	VBUS_STAT
USB SDP (USB500)	High	500mA	001
USB DCP / Adapter	Low	3.25A	010

9.2.3.3.2 Force Input Current Limit Detection

In host mode, the host can force the device to run by setting FORCE_DPDM bit. After the detection is completed, FORCE_DPDM bit returns to 0 by itself and Input Result is updated.

9.2.3.4 Input Voltage Limit Threshold Setting (VINDPM Threshold)

The device supports wide range of input voltage limit (3.9 V – 14 V) for high voltage charging and provides two methods to set Input Voltage Limit (VINDPM) threshold to facilitate autonomous detection.

1. Absolute VINDPM (FORCE_VINDPM=1)

By setting FORCE_VINDPM bit to 1, the VINDPM threshold setting algorithm is disabled. Register VINDPM is writable and allows host to set the absolute threshold of VINDPM function.

2. Relative VINDPM based on VINDPM_OS registers (FORCE_VINDPM=0) (Default)

When FORCE_VINDPM bit is 0 (default), the VINDPM threshold setting algorithm is enabled. The VINDPM register is read only and the charger controls the register by using VINDPM Threshold setting algorithm. The algorithm allows a wide range of adapter (V_{VBUS_OP}) to be used with flexible VINDPM threshold.

After Input Voltage Limit Threshold is set, an INT pulse is generated to signal to the host.

9.2.3.5 Converter Power-Up

After the input current limit is set, the converter is enabled and the HSFET and LSFET start switching. If battery charging is disabled, BATFET turns off. Otherwise, BATFET stays on to charge the battery.

The device provides soft-start when system rail is ramped up. When the system rail is below 2.2 V, the input current limit is forced to the lower of 200 mA or IINLIM register setting. After the system rises above 2.2 V, the device limits input current to the lower value of ILIM pin and IILIM register (ICO_EN = 0) or IDPM_LIM register (ICO_EN = 1).

As a battery charger, the device deploys a highly efficient 1.5 MHz step-down switching regulator. The fixed frequency oscillator keeps tight control of the switching frequency under all conditions of input voltage, battery voltage, charge current and temperature, simplifying output filter design.

A type III compensation network allows using ceramic capacitors at the output of the converter. An internal sawtooth ramp is compared to the internal error control signal to vary the duty cycle of the converter. The ramp height is proportional to the PMID voltage to cancel out any loop gain variation due to a change in input voltage.

In order to improve light-load efficiency, the device switches to PFM control at light load when battery is below minimum system voltage setting or charging is disabled. During the PFM operation, the switching duty cycle is set by the ratio of SYS and VBUS.

9.2.4 Input Current Optimizer (ICO)

The device provides innovative Input Current Optimizer (ICO) to identify maximum power point without overload the input source. The algorithm automatically identify maximum input current limit of power source without entering VINDPM to avoid input source overload.

This feature is enabled by default (ICO_EN=1) and can be disabled by setting ICO_EN bit to 0. After DCP or MaxCharge type input source is detected based on the procedures previously described ([Input Source Type Detection](#)). The algorithm runs automatically when ICO_EN bit is set. The algorithm can also be forced to execute by setting FORCE_ICO bit regardless of input source type detected.

The actual input current limit used by the [Dynamic Power Management](#) is reported in IDPM_LIM register while Input Current Optimizer is enabled (ICO_EN = 1) or set by IINLIM register when the algorithm is disabled (ICO_EN = 0). In addition, the current limit is clamped by ILIM pin unless EN_ILIM bit is 0 to disable ILIM pin function.

9.2.5 Boost Mode Operation from Battery

The device supports boost converter operation to deliver power from the battery to other portable devices through USB port. The boost mode output current rating meets the USB On-The-Go 500 mA (BOOST_LIM bits = 000) output requirement. The maximum output current is up to 2 A. The boost operation can be enabled if the conditions are valid:

1. BAT above BAT_{LOWV}
2. VBUS less than $BAT + V_{SLEEP}$ (in sleep mode)
3. Boost mode operation is enabled (OTG pin HIGH and OTG_CONFIG bit =1)
4. Voltage at TS (thermistor) pin is within range configured by Boost Mode Temperature Monitor as configured by BHOT and BCOLD bits
5. After 30 ms delay from boost mode enable

In boost mode, the device employs a 500 KHz or 1.5 MHz (selectable using BOOST_FREQ bit) step-up switching regulator based on system requirements. To avoid frequency change during boost mode operations, write to boost frequency configuration bit (BOOST_FREQ) is ignored when OTG_CONFIG is set.

During boost mode, the status register VBUS_STAT bits is set to 111, the VBUS output is 5V by default (selectable via BOOSTV register bits) and the output current can reach up to 2 A, selected via I²C (BOOST_LIM bits). The boost output is maintained when BAT is above V_{OTG_BAT} threshold

9.2.6 Power Path Management

The device accommodates a wide range of input sources from USB, wall adapter, to car battery. The device provides automatic power path selection to supply the system (SYS) from input source (VBUS), battery (BAT), or both.

9.2.6.1 Narrow VDC Architecture

The device deploys Narrow VDC architecture (NVDC) with BATFET separating system from battery. The minimum system voltage is set by SYS_MIN bits. Even with a fully depleted battery, the system is regulated above the minimum system voltage (default 3.5 V).

When the battery is below minimum system voltage setting, the BATFET operates in linear mode (LDO mode), and the system is regulated above the minimum system voltage setting. As the battery voltage rises above the minimum system voltage, BATFET is fully on and the voltage difference between the system and battery is the V_{DS} of BATFET. The status register VSYS_STAT bit goes high when the system is in minimum system voltage regulation.

图 9. V(SYS) vs V(BAT)

9.2.6.2 Dynamic Power Management

To meet maximum current limit in USB spec and avoid over loading the adapter, the device features Dynamic Power Management (DPM), which continuously monitors the input current and input voltage. When input source is over-loaded, either the current exceeds the input current limit (IINLIM or IDPM_LIM) or the voltage falls below the input voltage limit (VINDPM). The device then reduces the charge current until the input current falls below the input current limit and the input voltage rises above the input voltage limit.

When the charge current is reduced to zero, but the input source is still overloaded, the system voltage starts to drop. Once the system voltage falls below the battery voltage, the device automatically enters the [Supplement Mode](#) where the BATFET turns on and battery starts discharging so that the system is supported from both the input source and battery.

During DPM mode, the status register bits VDPM_STAT (VINDPM) and/or IDPM_STAT (IINDPM) is/are set high. [图 10](#) shows the DPM response with 9V/1.2A adapter, 3.2-V battery, 2.8-A charge current and 3.4-V minimum system voltage setting.

图 10. DPM Response

9.2.6.3 Supplement Mode

When the system voltage falls below the battery voltage, the BATFET turns on and the BATFET gate is regulated the gate drive of BATFET so that the minimum BATFET VDS stays at 30 mV when the current is low. This prevents oscillation from entering and exiting the [Supplement Mode](#). As the discharge current increases, the BATFET gate is regulated with a higher voltage to reduce $R_{DS(ON)}$ until the BATFET is in full conduction. At this point onwards, the BATFET VDS linearly increases with discharge current. [图 11](#) shows the V-I curve of the BATFET gate regulation operation. BATFET turns off to exit [Supplement Mode](#) when the battery is below battery depletion threshold.

图 11. BATFET V-I Curve

9.2.7 Battery Charging Management

The device charges 1-cell Li-Ion battery with up to 3-A charge current for high capacity battery. The 11-mΩ BATFET improves charging efficiency and minimize the voltage drop during discharging.

9.2.7.1 Autonomous Charging Cycle

With battery charging is enabled (CHG_CONFIG bit = 1 and $\overline{CE}$ pin is low), the device autonomously completes a charging cycle without host involvement. The device default charging parameters are listed in . The host can always control the charging operations and optimize the charging parameters by writing to the corresponding registers through I²C.

表 2. Charging Parameter Default Setting

DEFAULT MODE	bq25896
Charging Voltage	4.208 V
Charging Current	2.048 A
Pre-charge Current	128 mA
Termination Current	256 mA
Temperature Profile	JEITA
Safety Timer	12 hour

A new charge cycle starts when the following conditions are valid:

- Converter starts
- Battery charging is enabled by setting CHG_CONFIG bit, /CE pin is low and ICHG register is not 0 mA
- No thermistor fault on TS pin
- No safety timer fault
- BATFET is not forced to turn off (BATFET_DIS bit = 0)

The charger device automatically terminates the charging cycle when the charging current is below termination threshold, charge voltage is above recharge threshold, and device not in DPM mode or thermal regulation. When a full battery voltage is discharged below recharge threshold (threshold selectable via VRECHG bit), the device automatically starts a new charging cycle. After the charge is done, either toggle $\overline{CE}$ pin or CHG_CONFIG bit can initiate a new charging cycle.

The STAT output indicates the charging status of charging (LOW), charging complete or charge disable (HIGH) or charging fault (Blinking). The STAT output can be disabled by setting STAT_DIS bit. In addition, the status register (CHRG_STAT) indicates the different charging phases: 00-charging disable, 01-precharge, 10-fast charge (constant current) and constant voltage mode, 11-charging done. Once a charging cycle is completed, an INT is asserted to notify the host.

9.2.7.2 Battery Charging Profile

The device charges the battery in three phases: preconditioning, constant current and constant voltage. At the beginning of a charging cycle, the device checks the battery voltage and regulates current / voltage.

表 3. Charging Current Setting

VBAT	CHARGING CURRENT	REG DEFAULT SETTING	CHRG_STAT
< 2 V	I _{BATSHORT}	–	01
2 V – 3 V	I _{PRECHG}	128 mA	01
> 3 V	I _{CHG}	2048 mA	10

If the charger device is in DPM regulation or thermal regulation during charging, the charging current can be less than the programmed value. In this case, termination is temporarily disabled and the charging safety timer is counted at half the clock rate.

图 12. Battery Charging Profile

9.2.7.3 Charging Termination

The device terminates a charge cycle when the battery voltage is above recharge threshold, and the current is below termination current. After the charging cycle is completed, the BATFET turns off. The converter keeps running to power the system, and BATFET can turn on again to engage [Supplement Mode](#).

When termination occurs, the status register CHRG_STAT is set to 11, and an INT pulse is asserted to the host. Termination is temporarily disabled when the charger device is in input current, voltage or thermal regulation. Termination can be disabled by writing 0 to EN_TERM bit prior to charge termination.

9.2.7.4 Resistance Compensation (IRCOMP)

For high current charging system, resistance between charger output and battery cell terminal such as board routing, connector, MOSFETs and sense resistor can force the charging process to move from constant current to constant voltage too early and increase charge time. To speed up the charging cycle, the device provides resistance compensation (IRCOMP) feature which can extend the constant current charge time to delivery maximum power to battery.

The device allows the host to compensate for the resistance by increasing the voltage regulation set point based on actual charge current and the resistance as shown below. For safe operation, the host should set the maximum allowed regulation voltage register (V_{CLAMP}) and the minimum resistance compensation (BATCOMP).

$$V_{REG_ACTUAL} = V_{REG} + \min(I_{CHRG_ACTUAL} \times BATCOMP, V_{CLAMP}) \quad (1)$$

9.2.7.5 Thermistor Qualification

9.2.7.5.1 JEITA Guideline Compliance in Charge Mode

To improve the safety of charging Li-ion batteries, JEITA guideline was released on April 20, 2007. The guideline emphasized the importance of avoiding a high charge current and high charge voltage at certain low and high temperature ranges.

The device continuously monitors battery temperature by measuring the voltage between the TS pins and ground, typically determined by a negative temperature coefficient thermistor (NTC) and an external voltage divider. The device compares this voltage against its internal thresholds to determine if charging is allowed. To initiate a charge cycle, the voltage on TS pin must be within the V_{T1} to V_{T5} thresholds. If TS voltage exceeds the T1–T5 range, the controller suspends charging and waits until the battery temperature is within the T1 to T5 range. At cool temperature (T1–T2), JEITA recommends the charge current to be reduced to at least half of the charge current or lower. At warm temperature (T3–T5), JEITA recommends charge voltage below nominal charge voltage.

The device provides flexible voltage/current settings beyond the JEITA requirement. The voltage setting at warm temperature (T3–T5) can be 200 mV below charge voltage (JEITA_VSET=0). The current setting at cool temperature (T1–T2) can be further reduced to 20% or 50% of fast charge current (JEITA_ISET bit).

图 13. TS Resistor Network

图 14. Charging Values

Assuming a 103AT NTC thermistor on the battery pack as shown in 图 13, the value RT1 and RT2 can be determined by using 公式 2: :

$$RT2 = \frac{V_{REGN} \times RTH_{COLD} \times RTH_{HOT} \times \left(\frac{1}{VT1} - \frac{1}{VT5} \right)}{RTH_{HOT} \times \left(\frac{V_{REGN}}{VT5} - 1 \right) - RTH_{COLD} \times \left(\frac{V_{REGN}}{VT1} - 1 \right)}$$

$$RT1 = \frac{\frac{V_{REGN}}{VT1} - 1}{\frac{1}{RT2} + \frac{1}{RTH_{COLD}}}$$

(2)

Select 0°C to 60°C range for Li-ion or Li-polymer battery,

$$RTH_{T1} = 27.28 \text{ k}\Omega$$

$$RTH_{T5} = 3.02 \text{ k}\Omega$$

$$RT1 = 5.24 \text{ k}\Omega$$

$RT2 = 30.31 \text{ k}\Omega$

9.2.7.5.2 Cold/Hot Temperature Window in Boost Mode

For battery protection during boost mode, the device monitors the battery temperature to be within the V_{BCOLDx} to V_{BHOTx} thresholds unless boost mode temperature is disabled by setting BHOT bits to 11. When temperature is outside of the temperature thresholds, the boost mode is suspended. Once temperature is within thresholds, the boost mode is recovered.

图 15. TS Pin Thermistor Sense Thresholds in Boost Mode

9.2.7.6 Charging Safety Timer

The device has built-in safety timer to prevent extended charging cycle due to abnormal battery conditions. The safety timer is 4 hours when the battery is below $V_{BATLOWV}$ threshold. The user can program fast charge safety timer through I²C (CHG_TIMER bits). When safety timer expires, the fault register CHRG_FAULT bits are set to 11 and an INT is asserted to the host. The safety timer feature can be disabled via I2C by setting EN_TIMER bit.

During input voltage, current or thermal regulation, the safety timer counts at half clock rate as the actual charge current is likely to be below the register setting. For example, if the charger is in input current regulation (IDPM_STAT = 1) throughout the whole charging cycle, and the safety time is set to 5 hours, the safety timer will expire in 10 hours. This half clock rate feature can be disabled by writing 0 to TMR2X_EN bit.

9.2.8 Battery Monitor

The device includes a battery monitor to provide measurements of VBUS voltage, battery voltage, system voltage, thermistor ratio, and charging current, and charging current based on the device modes of operation. The measurements are reported in Battery Monitor Registers (REG0E-REG12). The battery monitor can be configured as two conversion modes by using CONV_RATE bit: one-shot conversion (default) and 1 second continuous conversion.

For one-shot conversion (CONV_RATE = 0), the CONV_START bit can be set to start the conversion. During the conversion, the CONV_START is set and it is cleared by the device when conversion is completed. The conversion result is ready after t_{CONV} (maximum 1 second).

For continuous conversion (CONV_RATE = 1), the CONV_RATE bit can be set to initiate the conversion. During active conversion, the CONV_START is set to indicate conversion is in progress. The battery monitor provides conversion result every 1 second automatically. The battery monitor exits continuous conversion mode when CONV_RATE is cleared.

When battery monitor is active, the REGN power is enabled and can increase device quiescent current. In battery only mode, the battery monitor is only active when $V_{(BAT)} > SYS_MIN$ setting in REG03.

表 4. Battery Monitor Modes of Operation

PARAMETER	REGISTER	MODES OF OPERATION			
		CHARGE MODE	BOOST MODE	DISABLE CHARGE MODE	BATTERY ONLY MODE
Battery Voltage (V_{BAT})	REG0E	Yes	Yes	Yes	Yes
System Voltage (V_{SYS})	REG0F	Yes	Yes	Yes	Yes
Temperature (TS) Voltage (V_{TS})	REG10	Yes	Yes	Yes	Yes
VBUS Voltage (V_{VBUS})	REG11	Yes	Yes	Yes	NA
Charge Current (I_{BAT})	REG12	Yes	NA	NA	NA

9.2.9 Status Outputs ($\overline{PG}$, STAT, and INT)

9.2.9.1 Power Good Indicator ($\overline{PG}$)

In bq25896, the $\overline{PG}$ goes LOW to indicate a good input source when:

1. VBUS above V_{VBUS_UVLO}
2. VBUS above battery (not in sleep)
3. VBUS below V_{ACOV} threshold
4. VBUS above $V_{VBUSMIN}$ (typical 3.8 V) when I_{BADSRC} (typical 30 mA) current is applied (not a poor source)
5. Completed

9.2.9.2 Charging Status Indicator (STAT)

The device indicates charging state on the open drain STAT pin. The STAT pin can drive LED as shown in . The STAT pin function can be disable by setting STAT_DIS bit.

表 5. STAT Pin State

CHARGING STATE	STAT INDICATOR
Charging in progress (including recharge)	LOW
Charging complete	HIGH
Sleep mode, charge disable	HIGH
Charge suspend (Input overvoltage, TS fault, timer fault, input or system overvoltage). Boost Mode suspend (due to TS Fault)	blinking at 1 Hz

9.2.9.3 Interrupt to Host (INT)

In some applications, the host does not always monitor the charger operation. The INT notifies the system on the device operation. The following events will generate 256- μ s INT pulse.

- USB/adaptor source identified (through PSEL or DPDM detection, with OTG pin)
- Good input source detected
 - VBUS above battery (not in sleep)
 - VBUS below V_{ACOV} threshold
 - VBUS above $V_{VBUSMIN}$ (typical 3.8 V) when I_{BADSRC} (typical 30 mA) current is applied (not a poor source)
- Input removed
- Charge Complete
- Any FAULT event in REG0C

When a fault occurs, the charger device sends out INT and keeps the fault state in REG0C until the host reads the fault register. Before the host reads REG0C and all the faults are cleared, the charger device would not send any INT upon new faults. To read the current fault status, the host has to read REG0C two times consecutively. The 1st read reports the pre-existing fault register status and the 2nd read reports the current fault register status.

9.2.10 BATET (Q4) Control

9.2.10.1 BATFET Disable Mode (Shipping Mode)

To extend battery life and minimize power when system is powered off during system idle, shipping, or storage, the device can turn off BATFET so that the system voltage is zero to minimize the battery leakage current. When the host set BATFET_DIS bit, the charger can turn off BATFET immediately or delay by t_{SM_DLY} as configured by BATFET_DLY bit.

9.2.10.2 BATFET Enable (Exit Shipping Mode)

When the BATFET is disabled (in shipping mode) and indicated by setting BATFET_DIS, one of the following events can enable BATFET to restore system power:

1. Plug in adapter
2. Clear BATFET_DIS bit
3. Set REG_RST bit to reset all registers including BATFET_DIS bit to default (0)
4. A logic high to low transition on $\overline{QON}$ pin with $t_{SHIPMODE}$ deglitch time to enable BATFET to exit shipping mode

9.2.10.3 BATFET Full System Reset

The BATFET functions as a load switch between battery and system when input source is not plugged-in. By changing the state of BATFET from off to on, system connects to SYS can be effectively have a power-on-reset. The $\overline{QON}$ pin supports push-button interface to reset system power without host by change the state of BATFET.

When the $\overline{QON}$ pin is driven to logic low for t_{QON_RST} (typical 15 seconds) while input source is not plugged in and BATFET is enabled (BATFET_DIS=0), the BATFET is turned off for t_{BATFET_RST} and then it is re-enabled to reset system power. This function can be disabled by setting BATFET_RST_EN bit to 0.

9.2.11 Current Pulse Control Protocol

The device provides the control to generate the VBUS current pulse protocol to communicate with adjustable high voltage adapter in order to signal adapter to increase or decrease output voltage. To enable the interface, the EN_PUMPX bit must be set. Then the host can select the increase/decrease voltage pulse by setting one of the PUMPX_UP or PUMPX_DN bit (but not both) to start the VBUS current pulse sequence. During the current pulse sequence, the PUMPX_UP and PUMPX_DN bits are set to indicate pulse sequence is in progress and the device pulses the input current limit between current limit set forth by IINLIM or IDPM_LIM register and the 100mA current limit ($I_{INDPM100_ACC}$). When the pulse sequence is completed, the input current limit is returned to value set by IINLIM or IDPM_LIM register and the PUMPX_UP or PUMPX_DN bit is cleared. In addition, the EN_PUMPX can be cleared during the current pulse sequence to terminate the sequence and force charger to return to input current limit as set forth by the IINLIM or IDPM_LIM register immediately. When EN_PUMPX bit is low, write to PUMPX_UP and PUMPX_DN bit would be ignored and have no effect on VBUS current limit.

9.2.12 Input Current Limit on ILIM

For safe operation, the device has an additional hardware pin on ILIM to limit maximum input current on ILIM pin. The input maximum current is set by a resistor from ILIM pin to ground as:

$$I_{NMAX} = \frac{K_{ILIM}}{R_{ILIM}} \quad (3)$$

The actual input current limit is the lower value between ILIM setting and register setting (IINLIM). For example, if the register setting is 111111 for 3.25 A, and ILIM has a 260-Ω resistor ($K_{ILIM} = 390$ max.) to ground for 1.5 A, the input current limit is 1.5 A. ILIM pin can be used to set the input current limit rather than the register settings when EN_ILIM bit is set. The device regulates ILIM pin at 0.8 V. If ILIM voltage exceeds 0.8 V, the device enters input current regulation (Refer to [Dynamic Power Management](#) section).

The ILIM pin can also be used to monitor input current when EN_ILIM is enabled. The voltage on ILIM pin is proportional to the input current. ILIM pin can be used to monitor the input current following 公式 4:

$$I_N = \frac{K_{ILIM} \times V_{ILIM}}{R_{ILIM} \times 0.8 \text{ V}} \quad (4)$$

For example, if ILIM pin is set with 260-Ω resistor, and the ILIM voltage is 0.4 V, the actual input current 0.615 A - 0.75 A (based on KILM specified). If ILIM pin is open, the input current is limited to zero since ILIM voltage floats above 0.8 V. If ILIM pin is short, the input current limit is set by the register.

The ILIM pin function can be disabled by setting EN_ILIM bit to 0. When the pin is disabled, both input current limit function and monitoring function are not available.

9.2.13 Thermal Regulation and Thermal Shutdown

9.2.13.1 Thermal Protection in Buck Mode

The device monitors the internal junction temperature T_J to avoid overheat the chip and limits the IC surface temperature in buck mode. When the internal junction temperature exceeds the preset thermal regulation limit (TREG bits), the device lowers down the charge current. The wide thermal regulation range from 60°C to 120°C allows the user to optimize the system thermal performance.

During thermal regulation, the actual charging current is usually below the programmed battery charging current. Therefore, termination is disabled, the safety timer runs at half the clock rate, and the status register THERM_STAT bit goes high.

Additionally, the device has thermal shutdown to turn off the converter and BATFET when IC surface temperature exceeds T_{SHUT} . The fault register CHRG_FAULT is set to 10 and an INT is asserted to the host. The BATFET and converter is enabled to recover when IC temperature is below T_{SHUT_HYS} .

9.2.13.2 Thermal Protection in Boost Mode

The device monitors the internal junction temperature to provide thermal shutdown during boost mode. When IC surface temperature exceeds T_{SHUT} , BATFET is turned off to disable battery discharge. When IC surface temperature is below T_{SHUT_HYS} , the host can use one of the method describes in section [BATFET Enable \(Exit Shipping Mode\)](#) to recover.

9.2.14 Voltage and Current Monitoring in Buck and Boost Mode

9.2.14.1 Voltage and Current Monitoring in Buck Mode

The device closely monitors the input and system voltage, as well as HSFET current for safe buck and boost mode operations.

9.2.14.1.1 Input Overvoltage (ACOV)

The input voltage for buck mode operation is V_{VBUS_OP} . If VBUS voltage exceeds V_{ACOV} , the device stops switching immediately. During input over voltage (ACOV), the fault register CHRG_FAULT bits sets to 01. An INT is asserted to the host..

9.2.14.1.2 System Overvoltage Protection (SYSOVP)

The charger device clamps the system voltage during load transient so that the components connect to system would not be damaged due to high voltage. When SYSOVP is detected, the converter stops immediately to clamp the overshoot.

9.2.14.2 Current Monitoring in Boost Mode

The device closely monitors the VBUS voltage, as well as RBFET and LSFET current to ensure safe boost mode operation.

9.2.14.2.1 VBUS Overcurrent Protection

The charger device closely monitors the RBFET (Q1), and LSFET (Q3) current to ensure safe boost mode operation. During overcurrent condition when output current exceed (I_{OTG_OCP}) the device operates in hiccup mode for protection. While in hiccup mode cycle, the device turns off RBFET for $t_{OTG_OCP_OFF}$ (30 ms typical) and turns on RBFET for $t_{OTG_OCP_ON}$ (250 μs typical) in an attempt to restart. If the overcurrent condition is removed, the boost converter returns to normal operation. When overcurrent condition continues to exist, the device repeats the hiccup cycle until overcurrent condition is removed. When overcurrent condition is detected the fault register bit BOOST_FAULT is set high to indicate fault in boost operation. An INT is also asserted to the host.

9.2.14.2.2 Boost Mode Overvoltage Protection

When the VBUS voltage rises above regulation target and exceeds V_{OTG_OVP} , the device enters overvoltage protection which stops switching, clears OTG_CONFIG bit and exits boost mode. During the overvoltage duration, the fault register bit (BOOST_FAULT) is set high to indicate fault in boost operation. An INT is also asserted to the host.

9.2.15 Battery Protection

9.2.15.1 Battery Overvoltage Protection (BATOVF)

The battery overvoltage limit is clamped at 4% above the battery regulation voltage. When battery over voltage occurs, the charger device immediately disables charge. The fault register BAT_FAULT bit goes high and an INT is asserted to the host.

9.2.15.2 Battery Over-Discharge Protection

When battery is discharged below V_{BAT_DPL} , the BATFET is turned off to protect battery from over discharge. To recover from over-discharge, an input source is required at VBUS. When an input source is plugged in, the BATFET turns on. The battery is charged with I_{BAT_SHORT} (typically 100 mA) current when the $V_{BAT} < V_{SHORT}$, or precharge current as set in IPRECHG register when the battery voltage is between V_{SHORT} and V_{BAT_LOWV} .

9.2.15.3 System Overcurrent Protection

When the system is shorted or significantly overloaded ($I_{BAT} > I_{BATOP}$) so that its current exceeds the overcurrent limit, the device latches off BATFET. Section [BATFET Enable \(Exit Shipping Mode\)](#) can reset the latch-off condition and turn on BATFET.

9.2.16 Serial Interface

The device uses I²C compatible interface for flexible charging parameter programming and instantaneous device status reporting. I²C is a bi-directional 2-wire serial interface. Only two open-drain bus lines are required: a serial data line (SDA) and a serial clock line (SCL). Devices can be considered as masters or slaves when performing data transfers. A master is the device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. At that time, any device addressed is considered a slave.

The device operates as a slave device with address 6BH, receiving control inputs from the master device like micro controller or a digital signal processor through REG00-REG14. Register read beyond REG14 (0x14) returns 0xFF. The I²C interface supports both standard mode (up to 100 kbits), and fast mode (up to 400 kbits). When the bus is free, both lines are HIGH. The SDA and SCL pins are open drain and must be connected to the positive supply voltage via a current source or pull-up resistor.

9.2.16.1 Data Validity

The data on the SDA line must be stable during the HIGH period of the clock. The HIGH or LOW state of the data line can only change when the clock signal on the SCL line is LOW. One clock pulse is generated for each data bit transferred.

图 16. Bit Transfer on the I²C Bus

9.2.16.2 START and STOP Conditions

All transactions begin with a START (S) and can be terminated by a STOP (P). A HIGH to LOW transition on the SDA line while SCL is HIGH defines a START condition. A LOW to HIGH transition on the SDA line when the SCL is HIGH defines a STOP condition.

START and STOP conditions are always generated by the master. The bus is considered busy after the START condition, and free after the STOP condition.

图 17. START and STOP conditions

9.2.16.3 Byte Format

Every byte on the SDA line must be 8 bits long. The number of bytes to be transmitted per transfer is unrestricted. Each byte has to be followed by an Acknowledge bit. Data is transferred with the Most Significant Bit (MSB) first. If a slave cannot receive or transmit another complete byte of data until it has performed some other function, it can hold the clock line SCL low to force the master into a wait state (clock stretching). Data transfer then continues when the slave is ready for another byte of data and release the clock line SCL.

图 18. Data Transfer on the I²C Bus

9.2.16.4 Acknowledge (ACK) and Not Acknowledge (NACK)

The acknowledge takes place after every byte. The acknowledge bit allows the receiver to signal the transmitter that the byte was successfully received and another byte may be sent. All clock pulses, including the acknowledge 9th clock pulse, are generated by the master.

The transmitter releases the SDA line during the acknowledge clock pulse so the receiver can pull the SDA line LOW and it remains stable LOW during the HIGH period of this clock pulse.

When SDA remains HIGH during the 9th clock pulse, this is the Not Acknowledge signal. The master can then generate either a STOP to abort the transfer or a repeated START to start a new transfer.

9.2.16.5 Slave Address and Data Direction Bit

After the START, a slave address is sent. This address is 7 bits long followed by the eighth bit as a data direction bit (bit R/W). A zero indicates a transmission (WRITE) and a one indicates a request for data (READ).

图 19. Complete Data Transfer

9.2.16.6 Single Read and Write

图 20. Single Write

图 21. Single Read

If the register address is not defined, the charger IC send back NACK and go back to the idle state.

9.2.16.7 Multi-Read and Multi-Write

The charger device supports multi-read and multi-write on REG00 through REG14 except REG0C.

图 22. Multi-Write

图 23. Multi-Read

REG0C is a fault register. It keeps all the fault information from last read until the host issues a new read. For example, if Charge Safety Timer Expiration fault occurs but recovers later, the fault register REG0C reports the fault when it is read the first time, but returns to normal when it is read the second time. In order to get the fault information at present, the host has to read REG0C for the second time. The only exception is NTC_FAULT which always reports the actual condition on the TS pin. In addition, REG0C does not support multi-read and multi-write.

9.3 Device Functional Modes

9.3.1 Host Mode and Default Mode

The device is a host controlled charger, but it can operate in default mode without host management. In default mode, the device can be used as an autonomous charger with no host or while host is in sleep mode. When the charger is in default mode, WATCHDOG_FAULT bit is HIGH. When the charger is in host mode, WATCHDOG_FAULT bit is LOW.

After power-on-reset, the device starts in default mode with watchdog timer expired, or default mode. All the registers are in the default settings.

In default mode, the device keeps charging the battery with 12-hour fast charging safety timer. At the end of the 12-hour, the charging is stopped and the buck converter continues to operate to supply system load. Any write command to device transitions the charger from default mode to host mode. All the device parameters can be programmed by the host. To keep the device in host mode, the host has to reset the watchdog timer by writing 1 to WD_RST bit before the watchdog timer expires (WATCHDOG_FAULT bit is set), or disable watchdog timer by setting WATCHDOG bits=00.

When the watchdog timer (WATCHDOG_FAULT bit = 1) is expired, the device returns to default mode and all registers are reset to default values except IINLIM, VINDPM, VINDPM_OS, BATFET_RST_EN, BATFET_DLY, and BATFET_DIS bits.

10 Application and Implementation

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

10.1 Application Information

A typical application consists of the device configured as an I²C controlled power path management device and a single cell battery charger for Li-Ion and Li-polymer batteries used in a wide range of smartphones and other portable devices. It integrates an input reverse-block FET (RBFET, Q1), high-side switching FET (HSFET, Q2), low-side switching FET (LSFET, Q3), and BATFET (Q4) between the system and battery. The device also integrates a bootstrap diode for the high-side gate drive.

10.2 Typical Application

图 46. bq25896 with PSEL Interface and USB On-the-Go (OTG)

10.2.1 Design Requirements

For this design example, use the parameters shown in 表 27.

表 27. Design Parameter

PARAMETERS	VALUES
Input voltage range	3.9 V to 14 V
Input current limit	1.5 A
Fast charge current	3008 mA
Output voltage	4.352 V
V _{REF} system pullup voltage	1.8 V - 3.3 V

10.2.2 Detailed Design Procedure

10.2.2.1 Inductor Selection

The device has 1.5 MHz switching frequency to allow the use of small inductor and capacitor values. The Inductor saturation current should be higher than the charging current (I_{CHG}) plus half the ripple current (I_{RIPPLE}):

$$I_{BAT} \geq I_{CHG} + (1/2) I_{RIPPLE} \quad (5)$$

The inductor ripple current depends on input voltage (V_{BUS}), duty cycle ($D = V_{BAT}/V_{BUS}$), switching frequency (f_s) and inductance (L):

$$I_{RIPPLE} = \frac{V_{BUS} \times D \times (1-D)}{f_s \times L} \quad (6)$$

The maximum inductor ripple current happens with $D = 0.5$ or close to 0.5. Usually inductor ripple is designed in the range of (20–40%) maximum charging current as a trade-off between inductor size and efficiency for a practical design.

10.2.2.2 Buck Input Capacitor

Input capacitor should have enough ripple current rating to absorb input switching ripple current. The worst case RMS ripple current is half of the charging current when duty cycle is 0.5. If the converter does not operate at 50% duty cycle, then the worst case capacitor RMS current I_{PMID} occurs where the duty cycle is closest to 50% and can be estimated by [公式 7](#):

$$I_{PMID} = I_{CHG} \times \sqrt{D \times (1-D)} \quad (7)$$

Low ESR ceramic capacitor such as X7R or X5R is preferred for input decoupling capacitor and should be placed to the drain of the high side MOSFET and source of the low side MOSFET as close as possible. Voltage rating of the capacitor must be higher than normal input voltage level. 25 V rating or higher capacitor is preferred for up to 14-V input voltage. 8.2-μF capacitance is suggested for typical of 3 A – 5 A charging current.

10.2.2.3 System Output Capacitor

Output capacitor also should have enough ripple current rating to absorb output switching ripple current. The output capacitor RMS current I_{COUT} is given:

$$I_{\text{CSYS}} = \frac{I_{\text{RIPPLE}}}{2 \times \sqrt{3}} \approx 0.29 \times I_{\text{RIPPLE}} \quad (8)$$

The output capacitor voltage ripple can be calculated as follows:

$$\Delta V_O = \frac{V_{\text{SYS}}}{8 LC_{\text{SYS}} f_s^2} \left(1 - \frac{V_{\text{SYS}}}{V_{\text{BUS}}} \right) \quad (9)$$

At certain input/output voltage and switching frequency, the voltage ripple can be reduced by increasing the output filter LC. The charger device has internal loop compensator. To get good loop stability, 1-μH and minimum of 20-μF output capacitor is recommended. The preferred ceramic capacitor is 6V or higher rating, X7R or X5R.

11 Power Supply Recommendations

In order to provide an output voltage on SYS, the device requires a power supply between 3.9 V and 14 V input with at least 100-mA current rating connected to VBUS or a single-cell Li-Ion battery with voltage $> V_{BATUVLO}$ connected to BAT. The source current rating needs to be at least 3 A in order for the buck converter of the charger to provide maximum output power to SYS.

12 Layout

12.1 Layout Guidelines

The switching node rise and fall times should be minimized for minimum switching loss. Proper layout of the components to minimize high frequency current path loop (see [图 58](#)) is important to prevent electrical and magnetic field radiation and high frequency resonant problems. Here is a PCB layout priority list for proper layout. Layout PCB according to this specific order is essential.

1. Place input capacitor as close as possible to PMID pin and GND pin connections and use shortest copper trace connection or GND plane.
2. Place inductor input terminal to SW pin as close as possible. Minimize the copper area of this trace to lower electrical and magnetic field radiation but make the trace wide enough to carry the charging current. Do not use multiple layers in parallel for this connection. Minimize parasitic capacitance from this area to any other trace or plane.
3. Put output capacitor near to the inductor and the IC. Ground connections need to be tied to the IC ground with a short copper trace connection or GND plane.
4. Route analog ground separately from power ground. Connect analog ground and connect power ground separately. Connect analog ground and power ground together using power pad as the single ground connection point. Or using a 0Ω resistor to tie analog ground to power ground.
5. Use single ground connection to tie charger power ground to charger analog ground. Just beneath the IC. Use ground copper pour but avoid power pins to reduce inductive and capacitive noise coupling.
6. Decoupling capacitors should be placed next to the IC pins and make trace connection as short as possible.
7. It is critical that the exposed power pad on the backside of the IC package be soldered to the PCB ground. Ensure that there are sufficient thermal vias directly under the IC, connecting to the ground plane on the other layers.
8. The via size and number should be enough for a given current path.

See the EVM design for the recommended component placement with trace and via locations. For the VQFN information, refer to [SCBA017](#) and [SLUA271](#).

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

NOTES: A. All linear dimensions are in millimeters

RTW (S-PWQFN-N24)

PLASTIC QUAD FLATPACK NO-LEAD

NOTES:

- A. All linear dimensions are in millimeters.
- B. This drawing is subject to change without notice.
- C. Publication IPC-7351 is recommended for alternate designs.
- D. This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat-Pack Packages, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <<http://www.ti.com>>.
- E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
- F. Customers should contact their board fabrication site for recommended solder mask tolerances and via tenting recommendations for vias placed in the thermal pad.
