

DAC11001B 20 位低噪声、超低谐波失真、快速稳定、高电压输出数模转换器 (DAC)

1 特性

- 20 位单调性：1LSB DNL (最大值)
- 积分线性：1LSB INL (最大值)
- 低噪声： $7\text{nV}/\sqrt{\text{Hz}}$
- 独立于代码的低干扰：1nV-s
- 出色的 THD：
在 $20\text{kHz } f_{\text{OUT}}$ 、 $1\text{MHz } f_{\text{DAC}}$ 下为 -118dB
- 快速稳定： $1\mu\text{s}$
- 灵活的输出范围： V_{REFPF} 至 V_{REFNF}
- 集成式精密反馈电阻器
- 50MHz、4 线 SPI 兼容接口
 - 读回
 - 菊花链
- 温度范围： -40°C 至 $+125^{\circ}\text{C}$
- 封装：48 引脚 TQFP

2 应用

- 实验室和现场仪表
- 光谱仪
- 模拟输出模块
- 电池测试
- 半导体测试
- 任意波形发生器 (AWG)
- MRI
- X 射线系统
- 专业音频放大器 (机架式)

3 说明

20 位 DAC11001B 是一款高精度、低噪声、电压输出、单通道数模转换器 (DAC)。DAC11001B 根据设计具有单调性，并可在所有输出范围内提供出色的线性度。

非缓冲电压输出可提供低噪声性能 ($7\text{nV}/\sqrt{\text{Hz}}$) 和快速稳定时间 ($1\mu\text{s}$)，因此这款器件非常适合低噪声、快速控制环路和波形生成应用。DAC11001B 兼具增强型抗尖峰脉冲电路以及独立于代码的超低干扰 (1nV-s)，可实现干净的波形斜坡和超低总谐波失真 (THD)。

DAC11001B 器件包含上电复位电路，因此 DAC 上电时使用寄存器中的已知值。使用外部基准，可以实现 V_{REFPF} 到 V_{REFNF} 的 DAC 输出，包括非对称输出范围。

DAC11001B 使用一个以高达 50MHz 的时钟速率运行的多功能 4 线制串行接口。

器件信息

器件型号	封装 ⁽¹⁾	封装尺寸 (标称值)
DAC11001B	TQFP (48)	7.00mm × 7.00mm

(1) 要了解所有可用封装，请参见数据表末尾的封装选项附录。

5 Pin Configuration and Functions

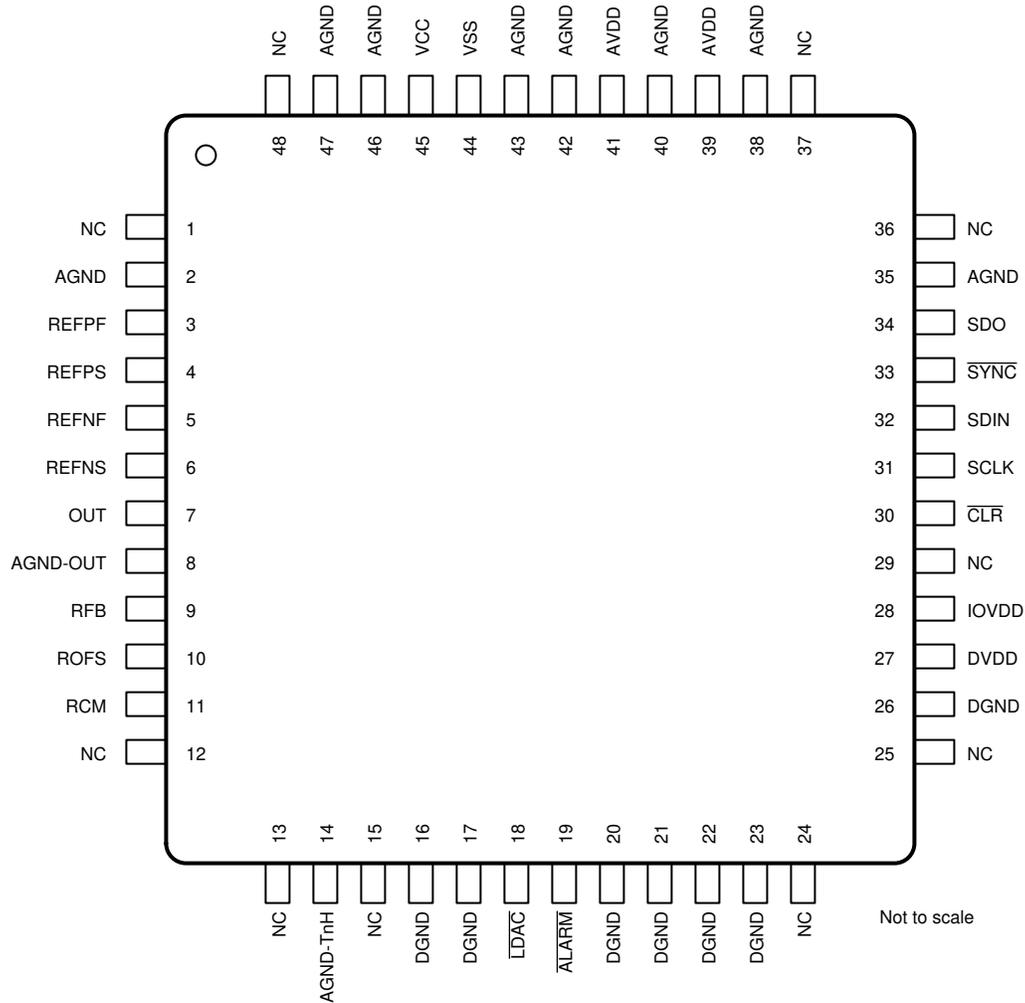

图 5-1. PFB Package, 48-Pin TQFP, Top View

表 5-1. Pin Functions

PIN		TYPE	DESCRIPTION
NAME	NO.		
AGND	2, 35, 38, 40, 42, 43, 46, 47	Analog ground	Connect to 0 V.
AGND-OUT	8	Analog ground	Connect to 0 V. Measure DAC output voltage with respect to this node.
AGND-TnH	14	Analog ground	Connect to 0 V. Integrated deglitcher clock ground.
ALARM	19	Output	Alarm output
AVDD	39, 41	Power	Positive low voltage analog power supply
CLR	30	Input	DAC registers clear pin, active low
DGND	16, 17, 20, 21, 22, 23, 26	Digital ground	Connect to 0 V.
DVDD	27	Power	Digital power supply pin
RFB	9	Input	Integrated precision resistor feedback node
IOVDD	28	Power	Interface power supply pin
LDAC	18	Input	Load DAC pin, active low
NC	1, 12, 13, 15, 24, 25, 29, 36, 37, 48	—	No connection, leave floating
OUT	7	Output	Unbuffered voltage output
RCM	11	Input	Integrated precision resistor common-mode node
REFNF	5	Input	External negative reference input. Connect to 0 V for unipolar DAC output.
REFNS	6	Input	External negative reference sense node
REFPF	3	Input	External positive reference input
REFPS	4	Input	External positive reference sense node
ROFS	10	Input	Integrated precision resistor offset node
SCLK	31	Input	Serial clock input of serial peripheral interface (SPI). Schmitt-trigger logic input. Data are transferred at rates of up to 50 MHz.
SDIN	32	Input	Serial data input. Schmitt-trigger logic input. Data are clocked into the input shift register on the falling edge of the serial clock input.
SDO	34	Output	Serial data output. Data are valid on the falling edge of SCLK.
SYNC	33	Input	SPI bus chip select input (active low). Data bits are not clocked into the serial shift register unless SYNC is low. When SYNC is high, the SDO pin is in high-impedance status.
VCC	45	Power	Analog positive power supply
VSS	44	Power	Analog negative power supply

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
Positive supply voltage	AV _{DD} to AGND	- 0.3	7	V
	V _{CC} to V _{SS}	- 0.3	40	
	V _{CC} to AGND	- 0.3	40	
Negative supply voltage	V _{SS} to AGND	- 19	0.3	V
Digital and IO supply voltage	DV _{DD} , IOV _{DD} to DGND	- 0.3	7	V
Positive reference voltage	V _{REFPF} to V _{REFNF}	- 0.3	40	V
	V _{REFPF} to V _{CC}	- 0.3	V _{CC} + 0.3	
	V _{REFPF} to AGND	- 0.3	40	
Negative reference voltage	V _{REFNF} to AGND	- 19	0.3	V
	V _{REFNF} to V _{SS}	V _{SS} - 0.3	0.3	
Digital input(s) to DGND		DGND - 0.3	IOV _{DD} + 0.3	V
OUT, RFB, RCM, ROFS pin voltage	to AGND (V _{SS} = AGND)	V _{SS}	V _{CC}	V
	to V _{SS}	0	V _{CC}	
Alarm pin voltage, ALARM to DGND		- 0.3	DV _{DD} + 0.3	V
Digital output, SDO to DGND		- 0.3	DV _{DD} + 0.3	V
Current into any pin		- 10	10	mA
T _J	Junction temperature		150	°C
T _{stg}	Storage temperature	- 65	150	°C

- (1) Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If used outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.

6.2 ESD Ratings

		VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins ⁽¹⁾	±1000
		Charged device model (CDM), per ANSI/ESDA/JEDEC JS-002, all pins ⁽²⁾	±250

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
	AV _{DD} to AGND	4.5		5.5	V
	V _{SS} to AGND	- 18		- 3	V
	V _{CC} to AGND	8		33	V
	V _{CC} to V _{SS}	11		36	V
	DV _{DD} to DGND	2.7		5.5	V
	IOV _{DD} to DGND	1.7		5.5	V
	AGND to DGND	- 0.3		0.3	V
	V _{IH} digital input high voltage	0.7 × IOV _{DD}			V
	V _{IL} digital input low voltage			0.3 × IOV _{DD}	V
	V _{REFPF} to AGND	3		15	V
	V _{REFNF} to AGND	- 15		0	V
	V _{REFPF} to V _{REFNF}	3		30	V
T _A	Operating temperature	- 40		125	°C

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾		DAC11001B	UNIT
		PFB (TQFP)	
		48 PINS	
R _{θJA}	Junction-to-ambient thermal resistance	51.0	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	10.3	°C/W
R _{θJB}	Junction-to-board thermal resistance	16.2	°C/W
Ψ _{JT}	Junction-to-top characterization parameter	0.3	°C/W
Ψ _{JB}	Junction-to-board characterization parameter	16.0	°C/W
R _{θJC(bot)}	Junction-to-case (bottom) thermal resistance	N/A	°C/W

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics application report](#).

6.5 Electrical Characteristics

at $T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$, $V_{CC} = +15\text{ V}$, $V_{SS} = -15\text{ V}$, $AV_{DD} = 5.5\text{ V}$, $DV_{DD} = 3.3\text{ V}$, $IOV_{DD} = 1.8\text{ V}$, see note⁽¹⁾ for V_{REFPF} and V_{REFNF} , OUT pin buffered with unity gain OPA827, ROFS, RCM, RFB unconnected, and all typical specifications at $T_A = 25^\circ\text{C}$, (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
STATIC PERFORMANCE						
	Resolution		20			Bits
INL	Relative accuracy ^{(2) (3)}	$T_A = 0^\circ\text{C}$ to 70°C ⁽⁴⁾ $V_{REFPF} = 10\text{ V}$ and $V_{REFNF} = 0\text{ V}$ $V_{REFPF} = +5\text{ V}$ and $V_{REFNF} = -5\text{ V}$	-1		1	LSB
		$T_A = 0^\circ\text{C}$ to 70°C ⁽⁴⁾	-1.25		1.25	
		$T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$	-2		2	
	Relative accuracy drift over time ⁽²⁾	$T_A = 25^\circ\text{C}$, 1000 hrs		± 0.1		LSB
DNL	Differential nonlinearity ^{(2) (3)}	$T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$	-1		1	LSB
	Zero code error ⁽⁴⁾	$T_A = 0^\circ\text{C}$ to 70°C , code 0d into DAC, unipolar ranges only	-4		4	LSB
		$T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$, code 0d into DAC, unipolar ranges only	-4		4	
		$T_A = 25^\circ\text{C}$, unipolar ranges only		± 2		
	Zero code error temperature coefficient	$T_A = 0^\circ\text{C}$ to 70°C , code 0d into DAC, unipolar ranges only		± 0.04		ppm FSR/ $^\circ\text{C}$
		$T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$, code 0d into DAC, unipolar ranges only		± 0.04		
	Gain error ^{(2) (4)}	$T_A = 0^\circ\text{C}$ to 70°C	-8		8	ppm of FSR
		$T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$	-10		10	
		$T_A = 25^\circ\text{C}$		± 2		
	Gain error temperature coefficient	$T_A = 0^\circ\text{C}$ to 70°C		± 0.04		ppm FSR/ $^\circ\text{C}$
		$T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$		± 0.04		
	Positive full-scale error ⁽⁴⁾	$T_A = 0^\circ\text{C}$ to 70°C , code 1048575d into DAC	-8		8	LSB
		$T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$, code 1048575d into DAC	-10		10	
		$T_A = 25^\circ\text{C}$, code 1048575d into DAC		± 2		
	Full-scale error temperature coefficient	$T_A = 0^\circ\text{C}$ to 70°C		± 0.04		ppm FSR/ $^\circ\text{C}$
		$T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$		± 0.04		
OUTPUT CHARACTERISTICS						
	Headroom	From V_{REFPF} to V_{CC}	5			V
	Footroom	From V_{REFNF} to V_{SS}	5			V
	DC impedance	From ROFS to RCM		5		k Ω
		From RCM to RFB		5		
Z_O	DC output impedance			2.5		k Ω
	Power supply rejection ratio (dc)	$V_{CC} = 15\text{ V} \pm 20\%$, $V_{SS} = -15\text{ V}$		1.5		$\mu\text{V/V}$
		$V_{CC} = 15\text{ V}$, $V_{SS} = -15\text{ V} \pm 20\%$		1		
	Output voltage drift over time	$T_A = 25^\circ\text{C}$, $V_{OUT} = \text{midscale}$, 1000 hr		1		ppm of FSR
VOLTAGE REFERENCE INPUT						
	Reference input impedance (REFPF)	DAC at midscale, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$		5.5		k Ω
	Reference input impedance (REFNF)	DAC at midscale, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$		7		

6.5 Electrical Characteristics (continued)

at $T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$, $V_{CC} = +15\text{ V}$, $V_{SS} = -15\text{ V}$, $AV_{DD} = 5.5\text{ V}$, $DV_{DD} = 3.3\text{ V}$, $IOV_{DD} = 1.8\text{ V}$, see note⁽¹⁾ for V_{REFPF} and V_{REFNF} , OUT pin buffered with unity gain OPA827, ROFS, RCM, RFB unconnected, and all typical specifications at $T_A = 25^\circ\text{C}$, (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
DYNAMIC PERFORMANCE						
t_s	Output voltage settling time ⁽⁵⁾	Full-scale settling to 0.1%FSR, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$		1		μs
		Full-scale settling to $\pm 1\text{ LSB}$, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$		3		
		1-mV step settling to $\pm 1\text{ LSB}$, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$		2.5		
SR	Slew rate ⁽⁶⁾	Full-scale step, measured at OUT pin, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$		30		$\text{V}/\mu\text{s}$
	Power-on glitch magnitude	Measured at unbuffered DAC voltage output, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$	-0.2			V
V_n	Output noise	0.1-Hz to 10-Hz, DAC at midscale, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$		0.4		μVpp
		100-kHz bandwidth, DAC at midscale, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$		3		μVrms
	Output noise density	Measured at 1 kHz, 10 kHz, 100 kHz, DAC at mid scale, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$		7		$\text{nV}/\sqrt{\text{Hz}}$
SFDR	Spurious free dynamic range ⁽⁶⁾	DAC update rate = 768 kHz, $f_{OUT} = 1\text{ kHz}$, $V_{REFPF} = 4.5\text{ V}$, $V_{REFNF} = -4.5\text{ V}$, sixth-order, low-pass, 30-kHz output filter		-120		dB
		DAC update rate = 768 kHz, $f_{OUT} = 20\text{ kHz}$, $V_{REFPF} = 4.5\text{ V}$, $V_{REFNF} = -4.5\text{ V}$, sixth-order, low-pass, 30-kHz output filter		-114		
		DAC update rate = 1 MHz, $f_{OUT} = 100\text{ kHz}$, $V_{REFPF} = 4.5\text{ V}$, $V_{REFNF} = -4.5\text{ V}$, sixth-order, low-pass, 150-kHz output filter		-92		
THD	Total harmonic distortion ⁽⁶⁾	DAC update rate = 768 kHz, $f_{OUT} = 1\text{ kHz}$, $V_{REFPF} = 4.5\text{ V}$, $V_{REFNF} = -4.5\text{ V}$, sixth-order, low-pass, 30-kHz output filter		-118		dB
		DAC update rate = 768 kHz, $f_{OUT} = 20\text{ kHz}$, $V_{REFPF} = 4.5\text{ V}$, $V_{REFNF} = -4.5\text{ V}$, sixth-order, low-pass, 30-kHz output filter		-118		
		DAC update rate = 1 MHz, $f_{OUT} = 100\text{ kHz}$, $V_{REFPF} = 4.5\text{ V}$, $V_{REFNF} = -4.5\text{ V}$, sixth-order, low-pass, 150-kHz output filter		-96		
	Power supply rejection ratio (ac)	200-mV, 50-Hz or 60-Hz sine wave superimposed on V_{SS} , $V_{CC} = 15\text{ V}$		95		dB
		200-mV, 50 Hz or 60 Hz sine wave superimposed on V_{CC} , $V_{SS} = -15\text{ V}$		95		
	Code change glitch impulse	$\pm 1\text{ LSB}$ change around mid code (including feedthrough), $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$, measured at output of buffer op amp		1		nV-s
	Code change glitch impulse magnitude	$\pm 1\text{ LSB}$ change around mid code (including feedthrough), $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$, measured at output of buffer op amp		5		mV
	Reference feedthrough	$V_{REFPF} = 10\text{ V} \pm 10\%$, $V_{REFNF} = 0\text{ V}$, frequency = 100 Hz, DAC at zero scale		-90		dB
		$V_{REFNF} = -10\text{ V} \pm 10\%$, $V_{REFPF} = 10\text{ V}$, frequency = 100 Hz, DAC at full scale		-90		
	Digital feedthrough	SCLK = 1 MHz, DAC static at midscale, $V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$		1		nV-s

6.5 Electrical Characteristics (continued)

at $T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$, $V_{CC} = +15\text{ V}$, $V_{SS} = -15\text{ V}$, $AV_{DD} = 5.5\text{ V}$, $DV_{DD} = 3.3\text{ V}$, $IOV_{DD} = 1.8\text{ V}$, see note⁽¹⁾ for V_{REFPF} and V_{REFNF} , OUT pin buffered with unity gain OPA827, ROFS, RCM, RFB unconnected, and all typical specifications at $T_A = 25^\circ\text{C}$, (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
DIGITAL INPUTS						
	Hysteresis voltage			0.4		V
	Input current			± 5		μA
	Pin capacitance	Per pin		10		pF
DIGITAL OUTPUTS						
V_{OL}	Low-level output voltage	Sinking 200 μA			0.4	V
V_{OH}	High-level output voltage	Sourcing 200 μA	IOV_{DD} - 0.5			V
	High impedance leakage			± 5		μA
	High impedance output capacitance			10		pF
POWER						
I_{AVDD}	Current flowing into AV_{DD}	$V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$, midscale code			2.5	mA
I_{VCC}	Current flowing into V_{CC}	$V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$, midscale code			15	mA
I_{VSS}	Current flowing into V_{SS}	$V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$, midscale code			15	mA
I_{DVDD}	Current flowing into DV_{DD}	$V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$, midscale code		0.5		mA
I_{IOVDD}	Current flowing into IOV_{DD}	$V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$, midscale code, all digital input pins static at IOV_{DD}		0.1		mA
I_{REFPF}	Reference input current (V_{REFPF})	$V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$, midscale code			7	mA
I_{REFNF}	Reference input current (V_{REFNF})	$V_{REFPF} = 10\text{ V}$, $V_{REFNF} = 0\text{ V}$, midscale code			7	mA

- (1) Specified for the following pairs: $V_{REFPF} = 5\text{ V}$ and $V_{REFNF} = 0\text{ V}$; $V_{REFPF} = 10\text{ V}$ and $V_{REFNF} = 0\text{ V}$; $V_{REFPF} = 5\text{ V}$ and $V_{REFNF} = -5\text{ V}$; $V_{REFPF} = 10\text{ V}$ and $V_{REFNF} = -10\text{ V}$.
- (2) Calculated between code 0d to 1048575d.
- (3) With device temperature calibration mode enabled and used.
- (4) Specified by design, not production tested.
- (5) Adaptive TnH mode. TnH action is disabled for large code steps. For small steps, TnH action happens with a hold time of 1.2 μs .
- (6) OUT pin buffered with unity gain OPA828.

6.6 Timing Requirements: Write, $4.5\text{ V} \leq \text{DV}_{\text{DD}} \leq 5.5\text{ V}$

all input signals are specified with $t_{\text{R}} = t_{\text{F}} = 1\text{ ns/V}$ (10% to 90% of IOV_{DD}) and timed from a voltage level of $(V_{\text{IL}} + V_{\text{IH}}) / 2$, SDO loaded with 20 pF, and $T_{\text{A}} = -40^{\circ}\text{C}$ to $+125^{\circ}\text{C}$ (unless otherwise noted)

		MIN	NOM	MAX	UNIT
f_{SCLK}	SCLK frequency, $1.7\text{ V} \leq \text{IOV}_{\text{DD}} < 2.7\text{ V}$			33	MHz
	SCLK frequency, $2.7\text{ V} \leq \text{IOV}_{\text{DD}} \leq 5.5\text{ V}$			50	
t_{SCLKHIGH}	SCLK high time, $1.7\text{ V} \leq \text{IOV}_{\text{DD}} < 2.7\text{ V}$	15			ns
	SCLK high time, $2.7\text{ V} \leq \text{IOV}_{\text{DD}} \leq 5.5\text{ V}$	10			
t_{SCLKLOW}	SCLK low time, $1.7\text{ V} \leq \text{IOV}_{\text{DD}} < 2.7\text{ V}$	15			ns
	SCLK low time, $2.7\text{ V} \leq \text{IOV}_{\text{DD}} \leq 5.5\text{ V}$	10			
t_{SDIS}	SDI setup, $1.7\text{ V} \leq \text{IOV}_{\text{DD}} < 2.7\text{ V}$	13			ns
	SDI setup, $2.7\text{ V} \leq \text{IOV}_{\text{DD}} \leq 5.5\text{ V}$	8			
t_{SDIH}	SDI hold, $1.7\text{ V} \leq \text{IOV}_{\text{DD}} < 2.7\text{ V}$	13			ns
	SDI hold, $2.7\text{ V} \leq \text{IOV}_{\text{DD}} \leq 5.5\text{ V}$	8			
t_{CSS}	$\overline{\text{SYNC}}$ falling edge to SCLK falling edge, $1.7\text{ V} \leq \text{IOV}_{\text{DD}} < 2.7\text{ V}$	23			ns

7 Detailed Description

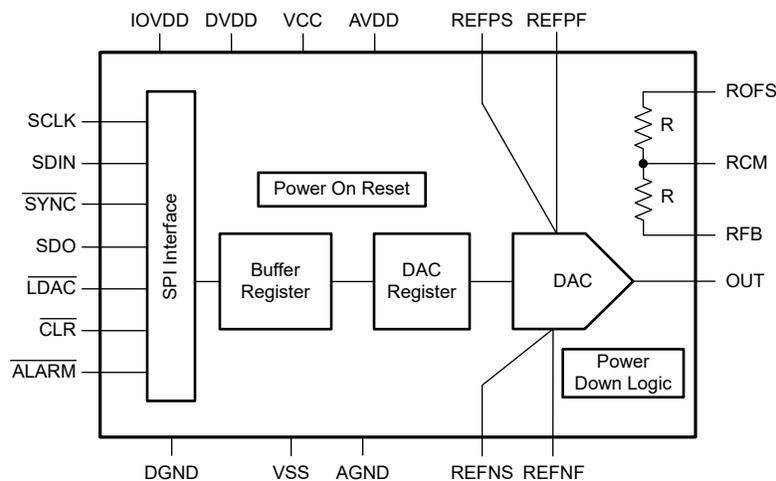

7.1 Overview

The 20-bit DAC11001B is a single-channel DAC. The unbuffered DAC output architecture is based on an R2R ladder that is designed to provide monotonicity and excellent linearity over wide reference and temperature ranges. This architecture provides a very low-noise ($7 \text{ nV}/\sqrt{\text{Hz}}$) and fast-settling ($1 \mu\text{s}$) output. The DAC11001B also implements a deglitch circuit that enables low, code-independent glitch at the DAC output. The deglitch circuit is extremely useful for creating ultra-low, harmonic-distortion waveform generation.

The DAC11001B requires external reference voltages on REFPPF and REFNF pins. The output of the DAC ranges from V_{REFNF} to V_{REFPPF} . See [节 6.3](#) for V_{REFPPF} and V_{REFNF} voltage ranges.

The DAC11001B also includes precision matched gain setting pins (ROFS, RCM, and RFB), Use these pins and an external op amp to scale the DAC output. The DAC11001B incorporates a power-on reset (POR) circuit to make sure that the DAC output powers up at zero scale, and remains at zero scale until a valid DAC command is issued. The DAC11001B uses a 4-wire serial interface that operates at clock rates of up to 50 MHz.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Digital-to-Analog Converter Architecture

The DAC11001B provides 20-bit monotonic outputs using an R2R ladder architecture. The DAC output ranges between V_{REFNF} and V_{REFPPF} based on the 20-bit DAC data, as described in [方程式 1](#):

$$V_{\text{OUT}} = (V_{\text{REFPPF}} - V_{\text{REFNF}}) \times \frac{\text{CODE}}{2^N} + V_{\text{REFNF}} \quad (1)$$

where

- CODE is the decimal equivalent of the DAC-DATA loaded to the DAC.
- N is the bits of resolution.
- V_{REFPPF} , V_{REFNF} is the reference voltage (positive and negative).

7.3.2 External Reference

The DAC11001B requires external references (REFPF and REFNF) to operate. See [§ 6.3](#) for V_{REFPF} and V_{REFNF} voltage ranges.

The DAC11001B also contains dedicated sense pins, REFPS for REFPF and REFNS for REFNF. The reference pins are unbuffered; therefore, use a reference driver circuit for these pins. Set the VREFVAL bits (address 02h) as per a reference span equal to $(V_{REFPF} - V_{REFNF})$. For example, the VREFVAL bits must be set to 0100 for $V_{REFPF} = 5\text{ V}$ and $V_{REFNF} = -5\text{ V}$.

[图 7-1](#) shows an example reference drive circuit for the DAC11001B. [表 7-1](#) shows the op-amp options for the reference driver circuit.

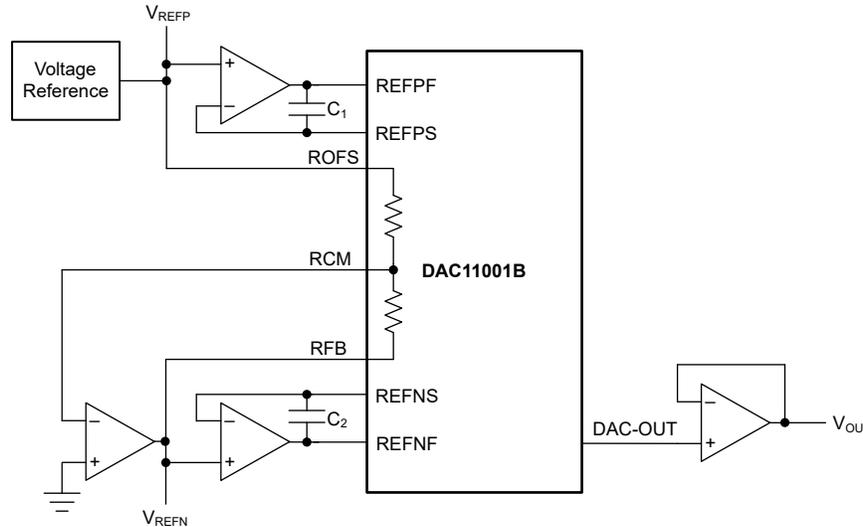

图 7-1. Reference Drive Circuit

表 7-1. Reference Op Amp Options

SELECTION PARAMETERS	OP AMPS
Low voltage and current noise	OPA211 , OPA827 , OPA828
Low offset and drift	OPA189

7.3.3 Output Buffers

The DAC11001B outputs are unbuffered. Use an external op amp to buffer the DAC output. The DAC output voltage ranges from V_{REFPF} to V_{REFNF} . Two gain-setting resistors are integrated in the DAC11001B. These resistors are used to scale the DAC output, minimize the bias current mismatch of the external op amp, and generate a negative reference for the REFNF pin. See [§ 8.3.3](#) for more information. [表 7-2](#) shows the op amp options for the output drive circuit.

表 7-2. Output Op Amp Options

SELECTION PARAMETERS	OP AMPS
Low bias current	OPA827 , OPA828
Low noise	OPA211 , OPA828
Low offset and drift	OPA189
Fast settling and low THD	OPA828

7.3.4 Internal Power-On Reset (POR)

The DAC11001B incorporates two internal POR circuits for the DV_{DD} , AV_{DD} , IOV_{DD} , V_{CC} , and V_{SS} supplies. The POR signals are ANDed together, so that all supplies must be at the minimum specified values for the device to *not* be in a reset condition. These POR circuits initialize internal registers, as well as set the analog outputs to a known state, all while the device supplies are ramping. All registers are reset to default values. The DAC11001B powers on with the DAC registers set to zero scale. The DAC output can be powered down by writing 1 to PDN (bit 4, address 02h). Typically, the POR function can be ignored as long as the device supplies power up and maintain the specified minimum voltage levels. However, a supply drop or brownout can trigger an internal POR reset event. [图 7-2](#) represents the internal POR threshold levels for the DV_{DD} , AV_{DD} , IOV_{DD} , V_{CC} , and V_{SS} supplies.

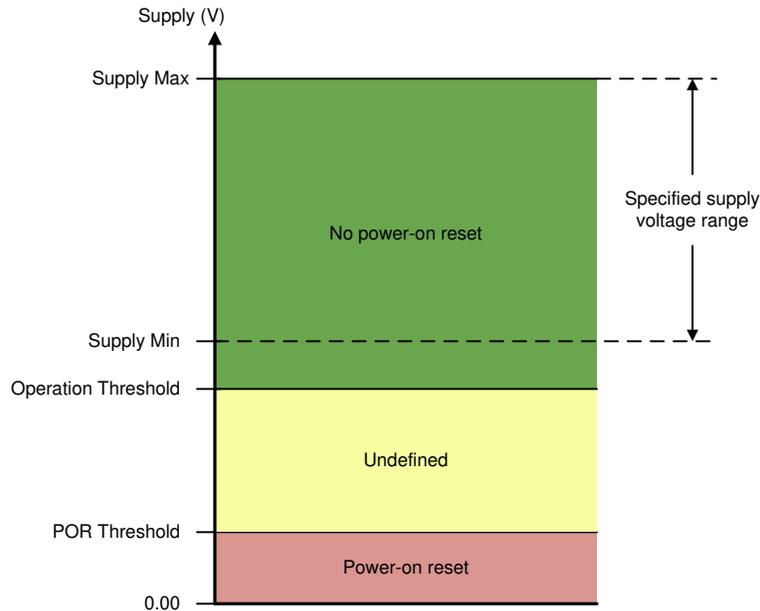

图 7-2. Relevant Voltage Levels for the POR Circuit

For the DV_{DD} supply, no internal POR occurs for nominal supply operation from 2.7 V (supply minimum) to 5.5 V (supply maximum). For a DV_{DD} supply region between 2.5 V (undefined operation threshold) and 1.6 V (POR threshold), the internal POR circuit may or may not provide a reset over all temperature conditions. For a DV_{DD} supply less than 1.6 V (POR threshold), the internal POR resets as long as the supply voltage is less than 1.6 V for approximately 1 ms.

For the AV_{DD} supply, no internal POR occurs for nominal supply operation from 4.5 V (supply minimum) to 5.5 V (supply maximum). For an AV_{DD} supply region between 4.1 V (undefined operation threshold) and 3.3 V (POR threshold), the internal POR circuit may or may not provide a reset over all temperature conditions. For an AV_{DD} supply less than 3.3 V (POR threshold), the internal POR resets as long as the supply voltage is less than 3.3 V for approximately 1 ms.

For the V_{CC} supply, no internal POR occurs for nominal supply operation from 8 V (supply minimum) to 36 V (supply maximum). For V_{CC} supply voltages between 7.5 V (undefined operation threshold) to 6 V (POR threshold), the internal POR circuit may or may not provide a reset over all temperature conditions. For a V_{CC} supply less than 6 V (POR threshold), the internal POR resets as long as the supply voltage is less than 6 V for approximately 1 ms.

For the V_{SS} supply, no internal POR occurs for nominal supply operation from -3 V (supply minimum) to -18 V (supply maximum). For V_{SS} supply voltages between -2.7 V (undefined operation threshold) to -1.8 V (POR threshold), the internal POR circuit may or may not provide a reset over all temperature conditions. For a V_{SS} supply greater than -1.8 V (POR threshold), the internal POR resets as long as the supply voltage is greater than -1.8 V for approximately 1 ms.

For the IOV_{DD} supply, no internal POR occurs for nominal supply operation from 1.8 V (supply minimum) to 5.5 V (supply maximum). For IOV_{DD} supply voltages between 1.5 V (undefined operation threshold) and 0.8 V (POR threshold), the internal POR circuit may or may not provide a reset over all temperature conditions. For an IOV_{DD} supply less than 0.8 V (POR threshold), the internal POR resets as long as the supply voltage is less than 0.8 V for approximately 1 ms.

In case the DV_{DD}, AV_{DD}, IOV_{DD}, V_{CC}, or V_{SS} supply drops to a level where the internal POR signal is indeterminate, power cycle the device followed by a software reset.

7.3.5 Temperature Drift and Calibration

The DAC11001B includes a calibration circuit that significantly reduces the temperature drift on integrated and differential nonlinearities. By default, this feature is disabled. Enable the temperature calibration feature by writing 1 to the EN_TMP_CAL bit (address 02h, B23). After the EN_TMP_CAL bit is set, issue a calibration cycle by writing 1 to RCLTMP (address 04h, B8). At this point, the device enters a calibration cycle. Do not issue any DAC update command during this period. The device has the capability to indicate the end of calibration using two methods:

1. Read the status bit ALM (address 05h, B12) using SPI.
2. Issue an alarm on the $\overline{\text{ALARM}}$ pin by setting logic 0. To enable this feature, write 1 to ENALMP bit (address 02h, B12).

After the calibration cycle completes, update the DAC code to observe the impact at the DAC output. If the environmental temperature changes after calibration, then recalibrate the device.

7.3.6 DAC Output Deglitch Circuit

The DAC11001B includes a deglitch (track-and-hold) circuit at the output. This circuit is enabled by default. The deglitch circuit minimizes the code-to-code glitch at the DAC output at the expense of the DAC update rate. This circuit is disabled by writing 1 to DIS_TNH (bit 7, address 06h). Disable this circuit to enable faster update of the DAC output, but with higher code-to-code glitches.

7.4 Device Functional Modes

7.4.1 Fast-Settling Mode and THD

The DAC11001B R2R ladder and deglitch circuit reduce the harmonic distortion for waveform generation applications. The fast settling bit (FSET, bit 10, address 02h) is set to 1 by default, so that the DAC is configured for enhanced THD performance. The FSET bit can be reset to 0 using an SPI write to enable fast-settling mode. In this mode, the DAC deglitcher circuit can be configured using TNH_MASK (bits 19:18, address 02h). These bits disable the deglitch circuit for code changes specified in [表 7-7](#). These bits are only writable when FSET = 0 (fast settling enabled) and DIS_TNH = 0 (deglitch circuit enabled).

7.4.2 DAC Update Rate Mode

The DAC11001B maximum update rate can be configured up to 1 MHz by using UP_RATE (bits 5:4, address 06h). These bits change the hold time of the deglitch circuit. The bits are set to a 0.8-MHz DAC update rate by default for enhanced THD performance. Changing the maximum update rate of the DAC impacts THD performance.

7.5 Programming

The DAC11001B is controlled through a flexible, four-wire serial interface that is compatible with serial interfaces used on many microcontrollers and DSP controllers. The interface provides read and write access to all registers of the DAC11001B. Additionally, the interface can be configured to daisy-chain multiple devices for write operations.

Each serial interface access cycle is exactly 32 bits long, as shown in [图 7-3](#). A frame is initiated by asserting the $\overline{\text{SYNC}}$ pin low. The frame ends when the $\overline{\text{SYNC}}$ pin is deasserted high. The first bit is read/write bit B31. A write is performed when this bit is set to 0, and a read is performed when this bit is set to 1. The next seven bits are address bits B30 to B24. The next 20 bits are data. For all writes, data are clocked on the falling edge of SCLK. As [图 7-4](#) shows, for read access and daisy-chain operation, the data are clocked out on the SDO terminal on the rising edge of SCLK.

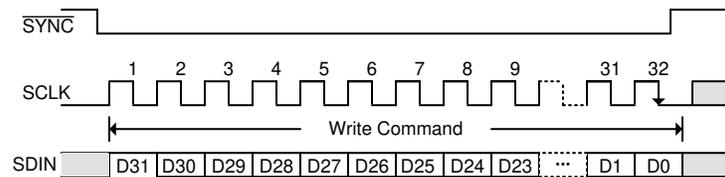

图 7-3. Serial Interface Write Bus Cycle: Standalone Mode

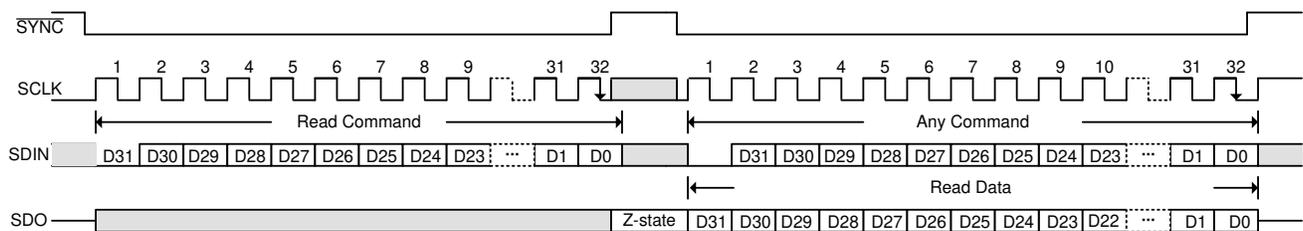

图 7-4. Serial Interface Read Bus Cycle

7.5.1 Daisy-Chain Operation

For systems that contain several DAC11001B devices, the SDO pin is used to daisy-chain the devices together. The daisy-chain feature is useful in reducing the number of serial interface lines. The first falling edge on the $\overline{\text{SYNC}}$ pin starts the operation cycle, as shown in [图 7-5](#). SCLK is continuously applied to the input shift register while the $\overline{\text{SYNC}}$ pin is kept low. The DAC is updated with the data on rising edge of $\overline{\text{SYNC}}$ pin.

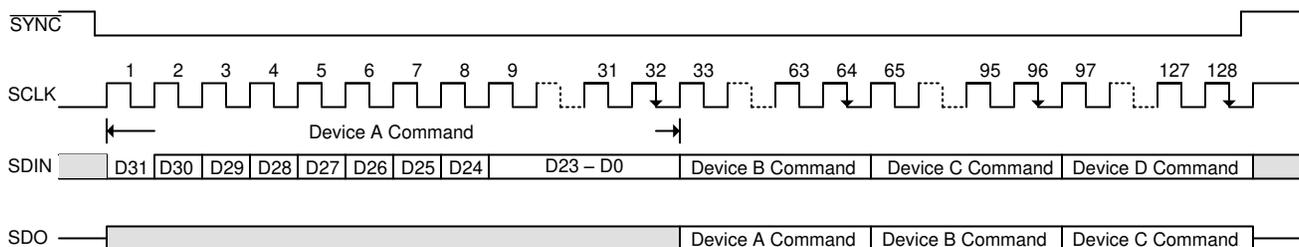

图 7-5. Serial Interface Daisy-Chain Write Cycle

If more than 32 clock pulses are applied, the data ripple out of the shift register and appear on the SDO line. These data are clocked out on the rising edge of SCLK and are valid on the falling edge. By connecting the SDO output of the first device to the SDI input of the next device in the chain, a multiple-device interface is constructed. Each device in the system requires 32 clock pulses.

As a result, the total number of clock cycles must be equal to $32 \times N$, where N is the total number of devices in the daisy-chain. When the serial transfer to all devices is complete the $\overline{\text{SYNC}}$ signal is taken high. This action transfers the data from the SPI shift registers to the internal register of each device in the daisy-chain and

prevents any further data from being clocked into the input shift register. The DAC11001B implements a bit that enables higher speeds for clocking out data from the SDO pin. Enable this feature by setting FSDO (bit 13, address 02h) to 1.

7.5.2 $\overline{\text{CLR}}$ Pin Functionality and Software Clear

The $\overline{\text{CLR}}$ pin is an asynchronous input pin to the DAC. When activated, this level-sensitive pin clears the DAC buffers and DAC latches to the DAC-CLEAR-DATA bits (address 03h). The device exits clear mode on the $\overline{\text{SYNC}}$ rising edge of the next valid write to the device. If the $\overline{\text{CLR}}$ pin receives a logic 0 during a write sequence during normal operation, the clear mode is activated and the buffer and DAC registers are immediately cleared. The DAC registers can also be cleared using the SCLR bit (address 04h, B5); the contents are cleared at the rising edge of $\overline{\text{SYNC}}$.

7.5.3 Output Update (Synchronous and Asynchronous)

The DAC11001B offers both a software and hardware simultaneous update and control function. The DAC double-buffered architecture has been designed so that new data can be entered for the DAC without disturbing the analog output. Data updates can be performed either in synchronous or in asynchronous mode, depending on the status of LDAC-MODE bit (address 02h, B14).

7.5.3.1 Synchronous Update

In synchronous mode (LDACMODE = 1), the $\overline{\text{LDAC}}$ pin is used as an active-low signal for simultaneous DAC updates. Data buffers must be loaded with the desired data before an $\overline{\text{LDAC}}$ low pulse. After an $\overline{\text{LDAC}}$ low pulse, the DAC is updated with the last contents of the corresponding data buffers. If the content of a data buffer is not changed, the DAC output remains unchanged after the $\overline{\text{LDAC}}$ pin is pulsed low.

7.5.3.2 Asynchronous Update

In asynchronous mode (LDACMODE = 0), data are updated with the rising edge of the $\overline{\text{SYNC}}$ (when daisy-chain mode is enabled, DSDO = 0), or at the 32nd falling edge of SCLK (When daisy-chain mode is disabled, DSDO = 1). For asynchronous updates, the $\overline{\text{LDAC}}$ pin is not required, and must be connected to 0 V permanently.

7.5.4 Software Reset Mode

The DAC11001B implements a software reset feature. The software reset function uses the SRST bit (address 04h, B6). When this bit is set to 1, the device resets to the default state.

8 Application and Implementation

备注

以下应用部分中的信息不属于 TI 器件规格的范围，TI 不担保其准确性和完整性。TI 的客户应负责确定器件是否适用于其应用。客户应验证并测试其设计，以确保系统功能。

8.1 Application Information

The DAC11001B is targeted for high-precision applications where ultra-high dc accuracy, ultra-low noise, fast settling, or high total harmonic distortion (THD) are required. The DAC11001B provides 20-bit monotonic resolution and excellent linearity. The DAC11001B finds application in high-performance source measure unit (SMU), arbitrary waveform generation (AWG). The DAC11001B is an also excellent choice for closed-loop control applications such as microelectromechanical system (MEMS) actuators, linear actuators, precision motor control, lens autofocus control in precision microscopy, lens control in mass spectrometer, beam control in electron beam lithography, and so on.

8.2 Typical Application

8.2.1 Source Measure Unit (SMU)

A source measure unit (SMU) is a common building block in memory and semiconductor test equipment and bench-top source measure units. A DAC is used in an SMU to force a desired voltage or a current to a device-under-test (DUT). 图 8-1 provides a simplified circuit diagram of the force-DAC in an SMU.

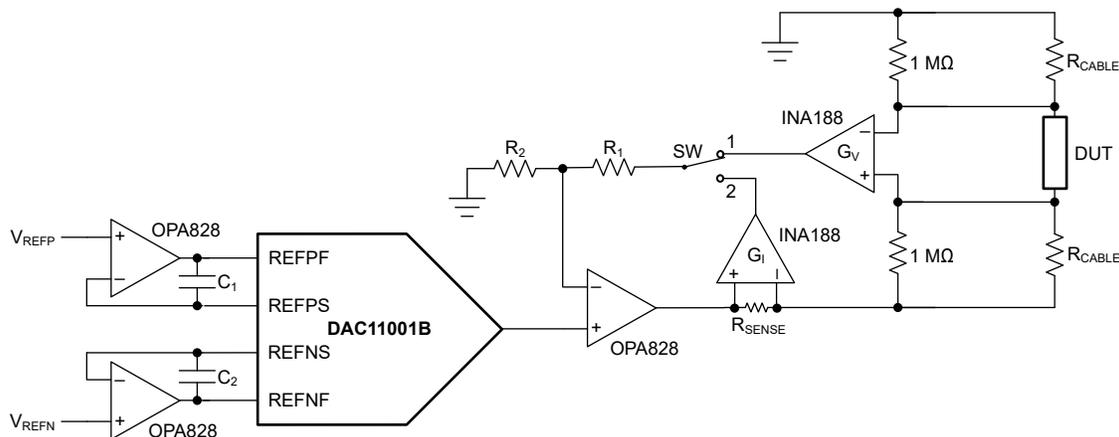

图 8-1. Source Measure Unit

8.2.1.1 Design Requirements

- Force voltage range: ± 10 V
- Force current range: ± 20 mA

8.2.1.2 Detailed Design Procedure

The DAC11001B is an excellent choice for this application to meet the 20-bit resolution requirement. Switch SW is used to toggle between force-voltage and force-current modes, as shown in 图 8-1. The OPA828 is a high-precision amplifier that provides a good balance between dc and ac performance, and can supply ± 30 -mA output current. The INA188 is a zero-drift instrumentation amplifier with gain selected with an external resistor. The external resistor is not shown in the drawing for simplicity. The gain resistor is not required for a gain of 1. 方程式 2 shows the calculation of the voltage gain when switch SW is in position 1.

$$A_V = \frac{1}{G_V} \times \left(1 + \frac{R_1}{R_2} \right) \quad (2)$$

Precision reference sources are available at 5 V or less. Use a ± 5 -V reference with a 2x gain configuration to get an output of ± 10 V. The DAC output amplifier sets the gain at 2, assuming $G_V = 1$, as shown in 方程式 3. R_1 and R_2 are 1-k Ω each. 方程式 3 shows the calculation for the current gain when the switch is in the position 2.

$$A_V = \frac{1}{R_{SENSE} \times G_1} \times \left(1 + \frac{R_1}{R_2} \right) \quad (3)$$

In order to get ± 20 -mA output current range with $R_1 = R_2$, $R_{SENSE} \times G_1$ must be 500. Set G_1 to 50 so that R_{SENSE} is 10- Ω . For a ± 20 -mA output current, the voltage drop across R_{SENSE} is ± 200 -mV. In case the design requires a lower voltage headroom, choose a higher value for G_1 and a smaller resistance value for R_{SENSE} .

There is no equation to select C_1 and C_2 . The values of C_1 and C_2 depend on the stability criteria of the reference buffers when driving the reference inputs of DAC11001B. The values are obtained through simulation. For the OPA828, use $C_1 = C_2 = 100$ pF. The 1-M Ω resistors in the circuit are used for making sure the amplifiers are not left in an open-loop state.

8.2.1.3 Application Curves

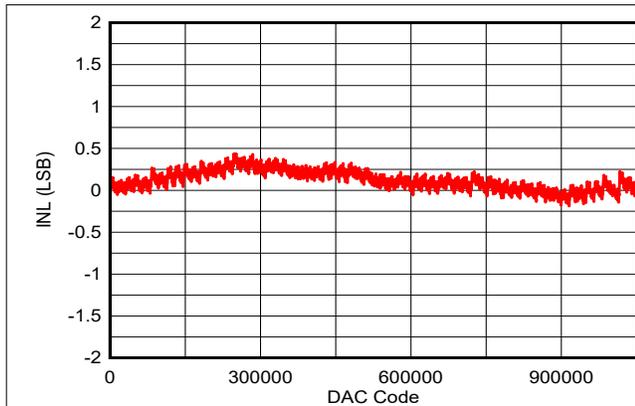

图 8-2. INL at ± 10 -V Output

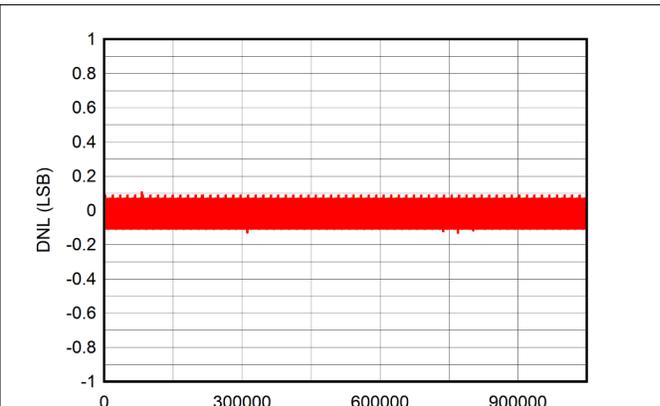

图 8-3. DNL at ± 10 -V Output

8.2.2 High-Precision Control Loop

High-precision control loops are used in precision motion-control applications, such as linear actuator control, servo motor control, galvanometer control, and more. The key requirements for such applications is resolution, monotonicity, settling time, and code-to-code glitch. 图 8-4 provides a simplified circuit of a linear actuator control circuit, wherein the DAC11001B commands the set point and an analog loop controls the actuator.

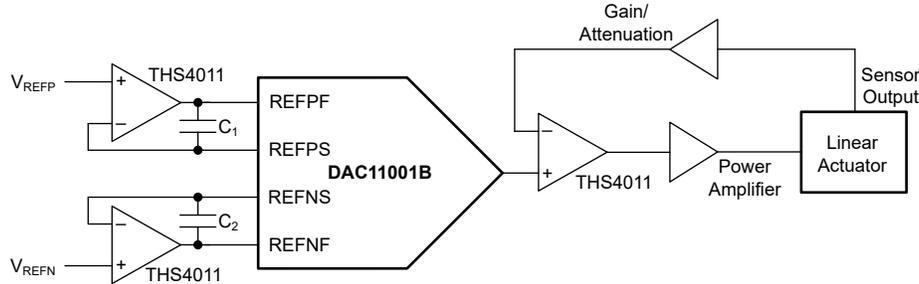

图 8-4. High-Precision Control Loop

8.2.2.1 Design Requirements

- DNL: ± 1 LSB max at 20-bits
- Settling time: $< 2 \mu\text{s}$
- Code-to-code glitch: $< 2 \text{ nV-s}$

8.2.2.2 Detailed Design Procedure

The DAC11001B provides 20-bit monotonic resolution at $< \pm 1$ LSB DNL. The device provides $< 2\text{-}\mu\text{s}$ settling time and $< 2\text{-nV-s}$ code-to-code glitch for major carry transition. The reference and output buffer used for this design is the THS4011, a high-speed amplifier with a 90-ns settling time. For the best settling response, use C_1 and C_2 between 10 pF to 50 pF.

8.2.2.3 Application Curves

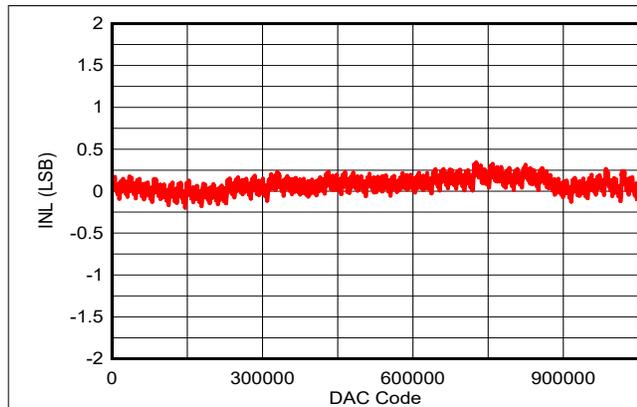

图 8-5. INL at $\pm 5\text{-V}$ Output

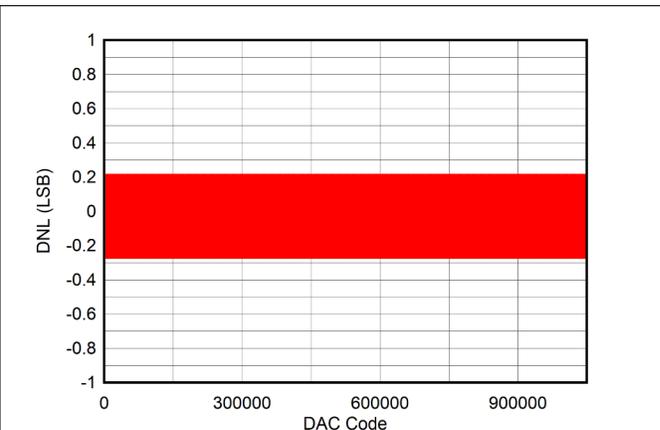

图 8-6. DNL at $\pm 5\text{-V}$ Output

8.2.3 Arbitrary Waveform Generation (AWG)

Arbitrary waveform generation circuits are common in memory and semiconductor test equipment. These circuits are used to generate reference ac waveforms to test semiconductor devices. The key performance parameters of such circuits are THD, SNR, and the update rate. 图 8-7 shows the basic building block example of an AWG circuit using the DAC11001B.

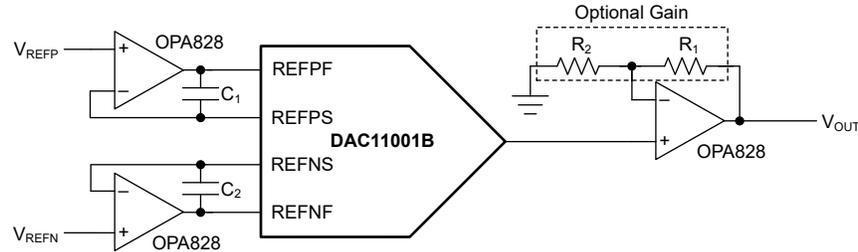

图 8-7. Arbitrary Waveform Generation

8.2.3.1 Design Requirements

- THD at 1 kHz: > - 105 dB
- Update rate: 768 kHz

8.2.3.2 Detailed Design Procedure

The DAC11001B provides a THD of - 115 dB at 1 kHz. The device provides update rates of up to 1 MHz, with marginal degradation in THD at higher frequencies. The OPA828 amplifier provides the best balance between the voltage and current noise densities, and is therefore an excellent choice to use as reference buffers. The OPA828 also offers low-distortion for high-THD applications.

8.2.3.3 Application Curves

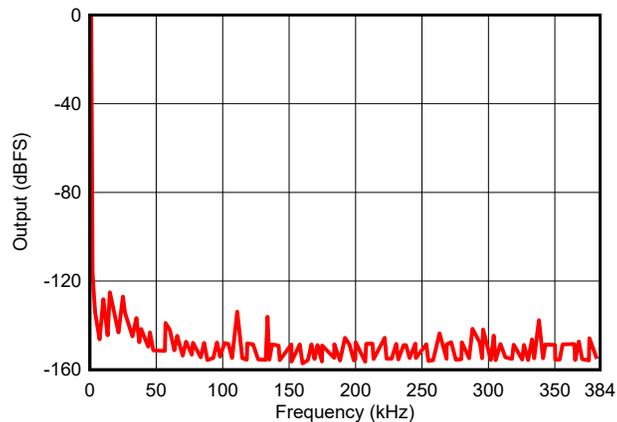

图 8-8. 1-kHz Spectrum vs Frequency

8.3 System Examples

This section provides details on the digital interface and the embedded resistor configurations.

8.3.1 Interfacing to a Processor

The DAC11001B works with a 4-wire SPI interface. The digital interface of the device to a processor is shown in [Figure 8-9](#). The DAC11001B has an $\overline{\text{LDAC}}$ input option for synchronous output update. In ac-signal-generation applications, the jitter in the $\overline{\text{LDAC}}$ signal contributes to signal-to-noise ratio (SNR). Therefore, the $\overline{\text{LDAC}}$ signal must be generated from a low-jitter timer in the processor. The $\overline{\text{CLR}}$ and $\overline{\text{ALARM}}$ pins are static signals, and therefore can be connected to general-purpose input-output (GPIO) pins on the processor. All active-low signals ($\overline{\text{SYNC}}$, $\overline{\text{LDAC}}$, $\overline{\text{CLR}}$, and $\overline{\text{ALARM}}$) must be pulled up to IOVDD using 10-k Ω resistors. $\overline{\text{ALARM}}$ is an output pin from the DAC; therefore, the corresponding GPIO on the processor must be configured as an input. Either poll the GPIO, or configure the GPIO as an interrupt to detect any failure alarm from the DAC. When using a high SCLK frequency, use source termination resistors, as shown in [Section 8.3.1](#). Typically, 33- Ω resistors work on printed circuit boards (PCBs) with a 50- Ω trace impedance.

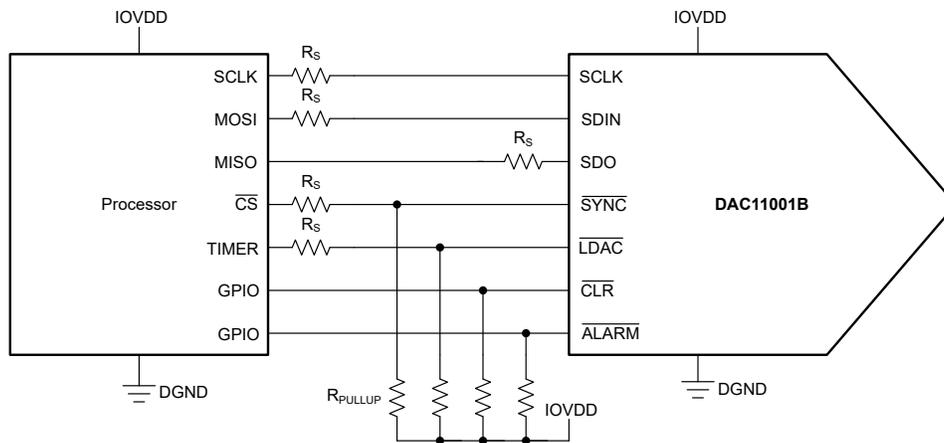

图 8-9. Interfacing to a Processor

8.3.2 Interfacing to a Low-Jitter $\overline{\text{LDAC}}$ Source

When the processor is not able to provide a low-jitter source for the $\overline{\text{LDAC}}$ signal, an external low-jitter LDAC source can be used, as shown in [Figure 8-10](#). The processor can take the $\overline{\text{LDAC}}$ signal as an interrupt and trigger the SPI frame synchronously.

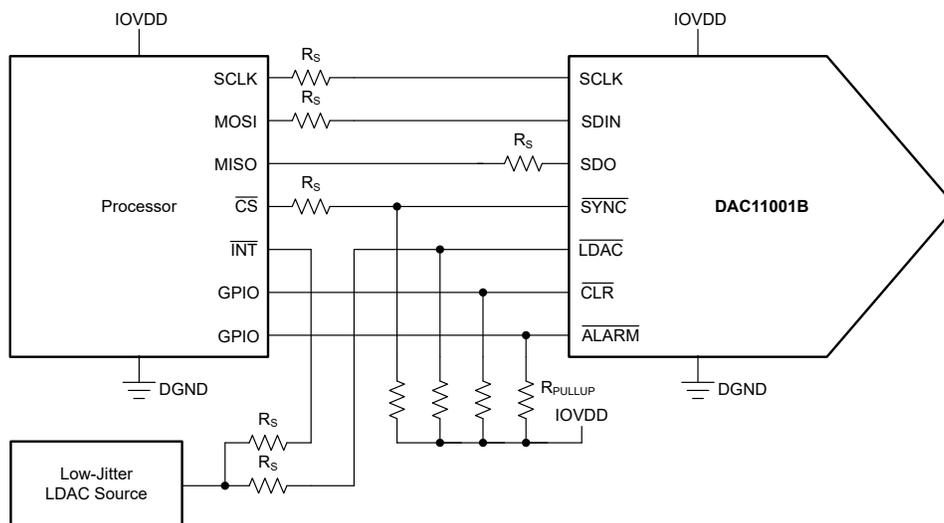

图 8-10. Interfacing to an External $\overline{\text{LDAC}}$ Source

8.3.3 Embedded Resistor Configurations

The DAC11001B provides two embedded resistors with values that are double the value of the output impedance of the R2R ladder. These resistors can be used in various configurations, as shown in the following subsections.

8.3.3.1 Minimizing Bias Current Mismatch

The bias current mismatch in the output amplifier can lead to offset error at the output. To minimize mismatch, the amplifier must have a matching resistor to that of the R2R output impedance on the feedback path. The feedback resistors are used in parallel for this purpose, as shown in [图 8-11](#). Some amplifiers may become unstable with a feedback resistor in the buffer configuration; therefore, a compensation capacitor (C_{COMP}) might be needed, as shown. The typical value of this capacitor is in the range of 22 pF to 100 pF, depending on the amplifier.

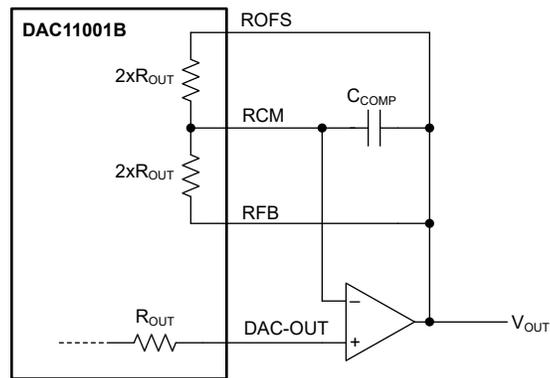

图 8-11. Minimizing Bias Current Mismatch

8.3.3.2 2x Gain Configuration

The circuit of [图 8-11](#) can be configured for 2x gain by connecting one of the resistor ends to ground, as shown in [图 8-12](#).

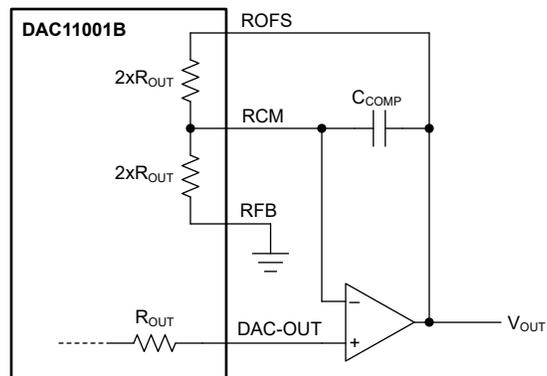

图 8-12. 2x Gain Configuration

8.3.3.3 Generating Negative Reference

Generating a negative reference is a challenge because of the fact that the circuit needs an inverting amplifier involving resistors. The resistor mismatch and temperature drift can lead to inaccuracy. The embedded, matched resistors in DAC11001B can be used as shown in [图 8-13](#), the inverting amplifier configuration, to generate an accurate negative reference voltage.

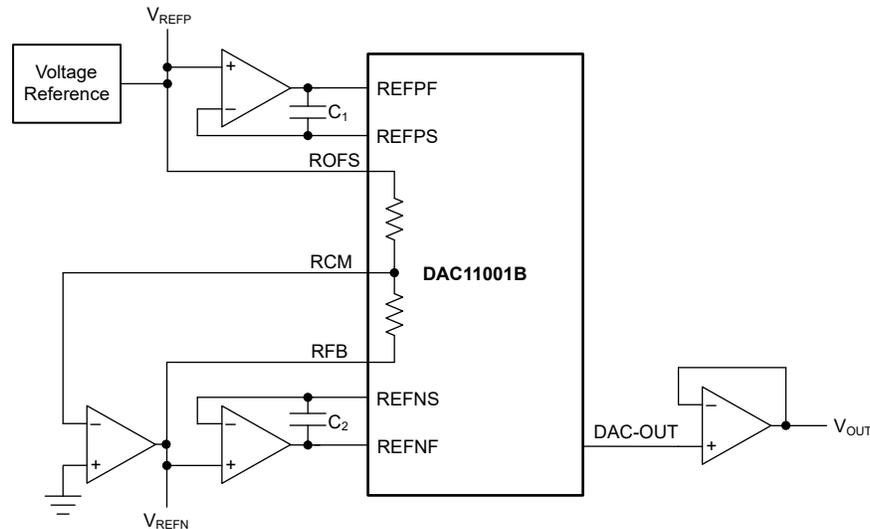

图 8-13. Generating Negative Reference

8.4 What to Do and What Not to Do

8.4.1 What to Do

- Follow recommended grounding, decoupling, and layout schemes for achieving best accuracy.
- Use a low-jitter $\overline{\text{LDAC}}$ source for best ac performance.
- Choose the appropriate amplifiers depending on the application requirements as explained in above sections.

8.4.2 What Not to Do

- Do not apply the reference before the DAC power supplies are powered on.
- Do not use the reference source directly with the DAC reference inputs without using buffers. or else the accuracy drastically degrades.

8.5 Initialization Set Up

The following text shows the pseudocode to get started with the DAC11001B:

```
//SPI Settings
//Mode: Mode-1 (CPOL: 0, CPHA: 1)
//CS Type: Active Low, Per Packet
//Frame length: 32
//SYNTAX: WRITE <REGISTER (HEX ADDRESS), <HEX DATA>
//Select VREF, TnH mode (Good THD), LDAC mode and power-up the DAC
WRITE CONFIG (0x02), 0x004C80
//Write zero code to the DAC
WRITE DACDATA (0x01), 0x000000
//Write mid code to the DAC
WRITE DACDATA (0x01), 0x7FFFF0
//Write full code to the DAC
WRITE DACDATA (0x01), 0xFFFFF0
```

9 Power Supply Recommendations

To get the best performance out of the DAC11001B, the power supply, grounding, and decoupling are very important. Use a PCB with a ground-plane reference, which helps in confining the digital return currents. A low mutual inductance path is created just beneath the high-frequency digital traces causing the return currents to follow the respective signal traces, thus minimizing crosstalk. On the other hand, dc signals spread over the ground plane without being confined below the signal trace. Therefore, in precision dc applications, limiting the common-impedance coupling is very difficult unless the ground planes are physically separated. 图 9-1 shows a method to divide the grounds so that there is no common-mode current flow between the grounds, while maintaining the same dc potential across all grounds. This circuit assumes that the REFGND and LOAD-GND are provided from isolated power sources, therefore, there is no common-mode current flow through the reference or the load.

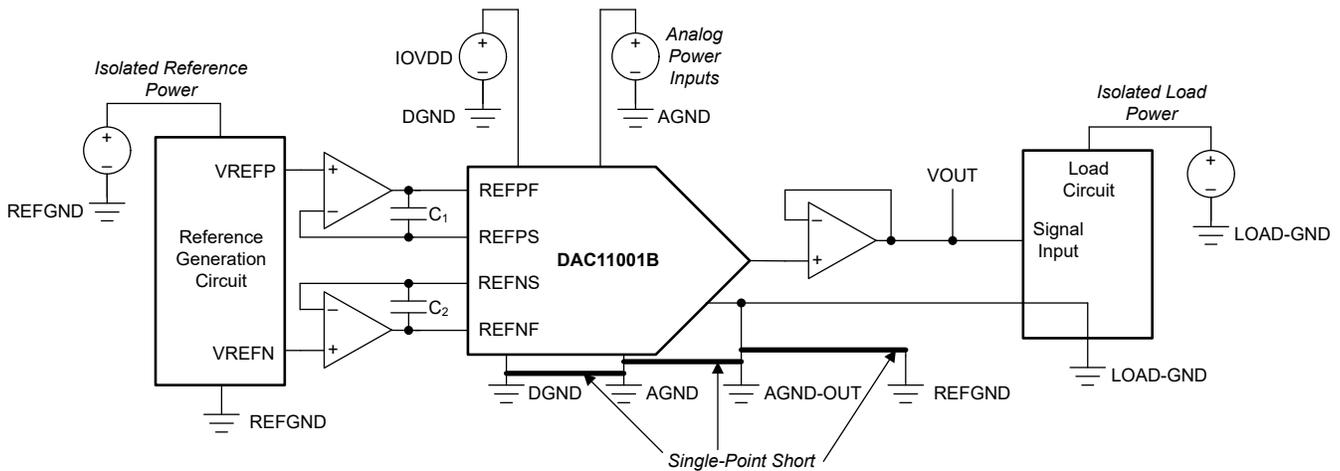

图 9-1. Power and Signal Grounding

When the load circuit is powered from a source referenced to AGND, and the LOAD-GND is shorted to AGND at the far end, the AGND-OUT must no longer be shorted to AGND locally near the DAC. The local shorting creates a ground loop, otherwise. The resulting connection that avoids the ground loop is shown in 图 9-2.

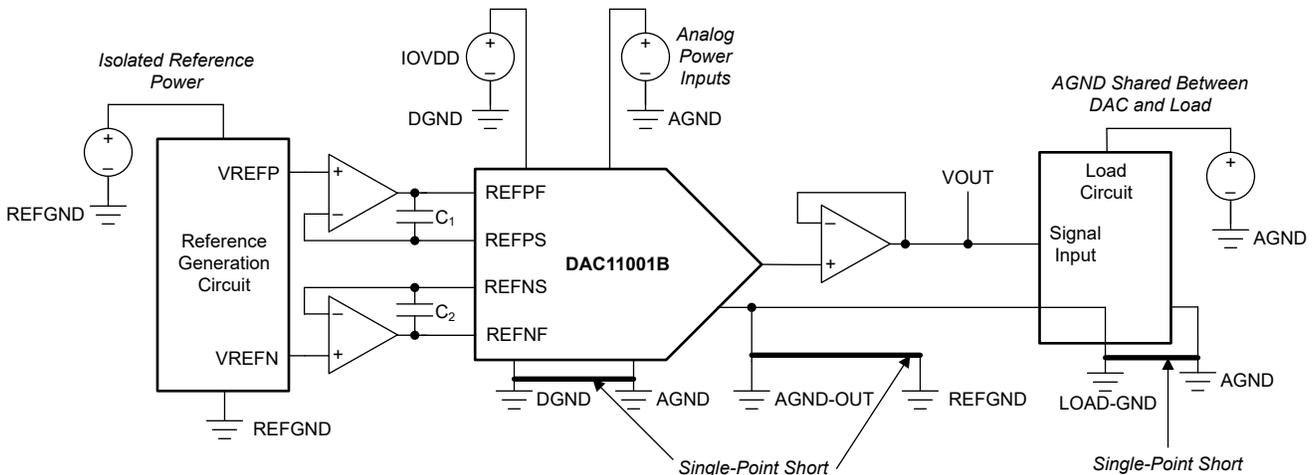

图 9-2. Grounding Scheme When AGND is Load Ground

When the reference source is powered from a power source with AGND as the ground, there is a possibility of common-impedance coupling causing a code-dependent shift in the reference voltage. To avoid undesired coupling, drive REFGND using a buffer that maintains the reference ground potential equals to that of AGND-OUT, as shown in 图 9-3.

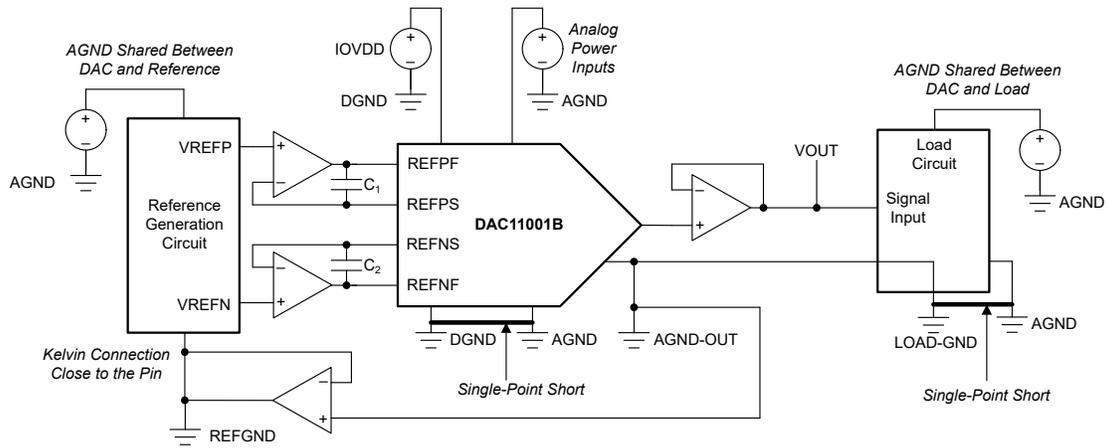

图 9-3. Connecting the Reference Ground

Channel-to-channel dc crosstalk is a major concern in multichannel applications, such as battery test equipment. While the DAC11001B is single-channel, the crosstalk problem can appear at a system level when using multiple DAC11001B devices. The problem becomes severe when the grounds of the loads are shorted together creating a possible ground loop. In such cases, avoid the local short between AGND and AGND-OUT. Use a single short between AGND and DGND for all the DACs. If the PCB layout allows for the digital signal and analog power supplies to be kept separate, DGND and AGND can be combined to a single ground plane. 图 9-4 shows an example circuit for minimizing dc crosstalk across DAC channels in a system.

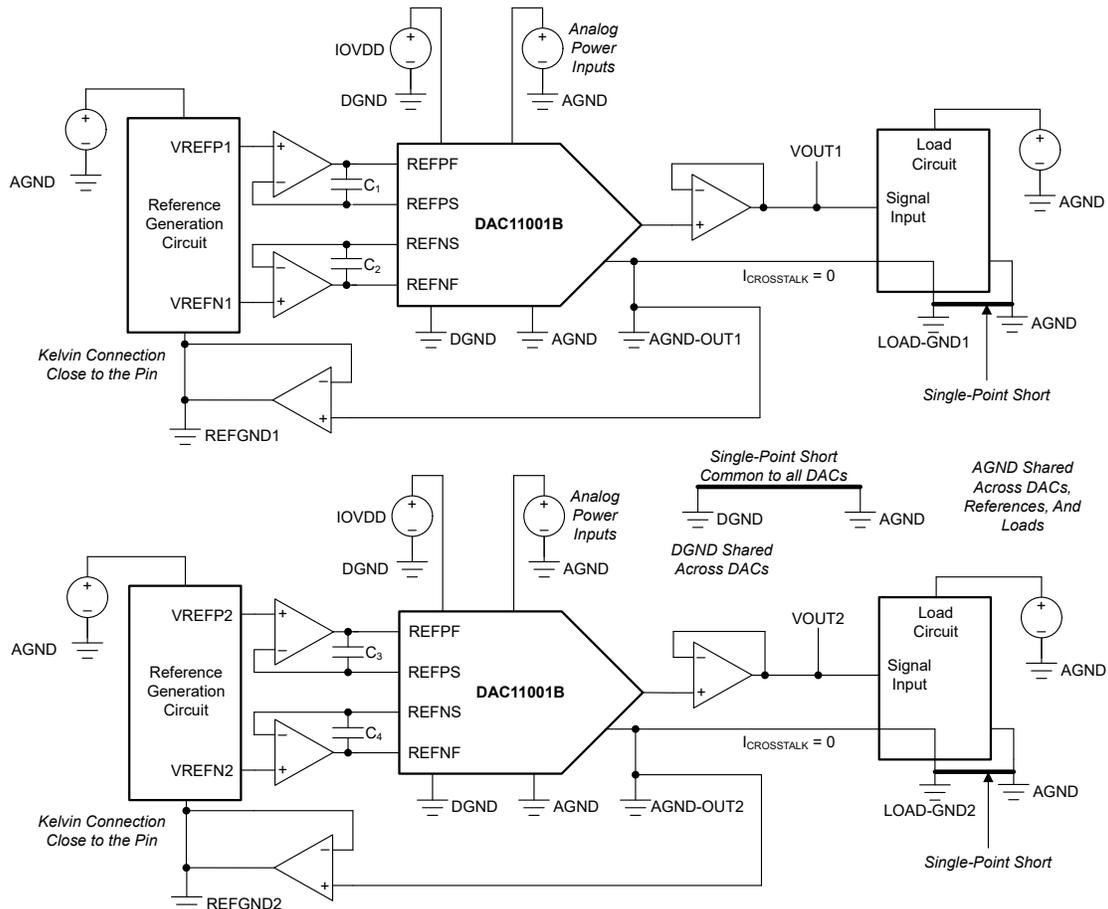

图 9-4. Minimizing Multichannel DC Crosstalk

Power-supply bypassing and decoupling is key to keeping power supply noise, switching transients, and common-mode currents away from the DAC output. There are three main objective of power-supply bypassing:

- *Filtering*: Filter out noise and ripple from power supplies
- *Bypassing*: Supply switching or load transient currents locally by avoiding trace inductances
- *Decoupling*: Stop local transient currents from impacting other circuits

To achieve these objectives, use the following 3-element scheme. Place a decoupling capacitor close to every power supply pin to provide the local current path for load and circuit switching transients. This capacitor must be referenced to the respective load ground for best load transient suppression. Use a 0.1- μF to 1- μF , X7R, multilayer ceramic capacitor (MLCC) for this purpose. For analog power supplies, a 10- Ω series resistor provides the best decoupling. For filtering the power-supply noise and ripple, 10- μF capacitors work best when placed at the power entry point of the board. An example decoupling scheme is shown in [图 9-5](#).

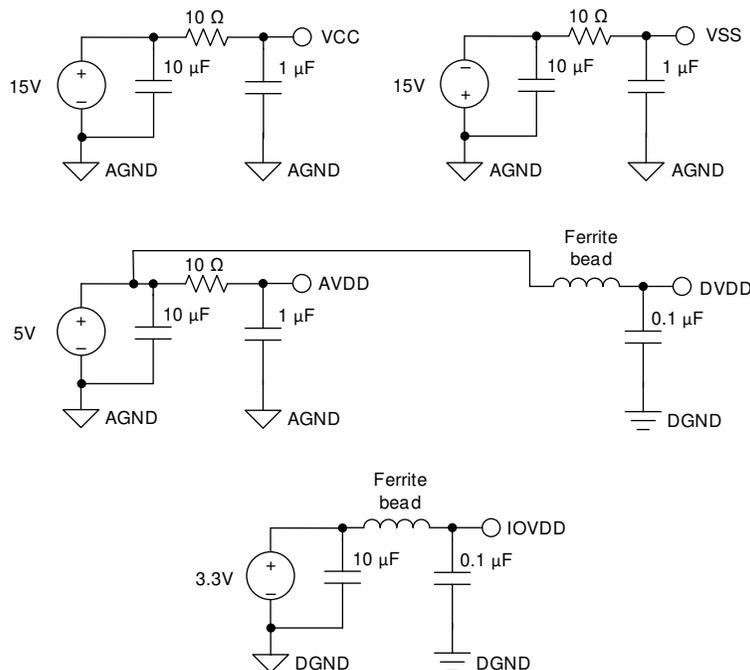

图 9-5. Power-Supply Decoupling

9.1 Power-Supply Sequencing

The DAC11001B does not require any power-supply sequence. However, the power supplies to the AVDD pin must be capable of providing 30-mA of current if V_{SS} ramps before AV_{DD} . This current is derived from the AVDD pin, and flows out of the VSS pin. This condition is transient, and the device stops consuming this current when the power supplies are ramped up. To avoid this condition, make sure to ramp AV_{DD} before V_{SS} .

10 Layout

10.1 Layout Guidelines

PCB layout plays a significant role for achieving desired ac and dc performance from the DAC11001B. The DAC11001B has a pinout that supports easy splitting of the noisy and quiet grounds. The digital signals are available on two adjacent sides of the device; whereas, the power and analog signals are available separate sides. [图 10-4](#) shows an example layout, where the different ground planes have been clearly demarcated. The figure also shows the best positions for the single-point shorts between the ground planes. For best power-supply bypassing, place the bypass capacitors close to the respective power pins as shown. Provide unbroken ground reference planes for the digital signal traces, especially for the SPI and LDAC signals.

10.1.1 PCB Assembly Effects on Precision

The printed-circuit board (PCB) assembly process, including reflow soldering, imparts thermal stresses on the device which can degrade the precision of the device and must be considered in the development of very-high-precision systems. Standard reflow guidelines must be followed to achieve the device specified performance. For more information please see Texas Instruments, [MSL Ratings and Reflow Profiles application report](#).

Baking the PCBs after the assembly process can restore the precision of the device to pre-assembly values. [图 10-1](#) to [图 10-3](#) show the effect of reflow soldering on the typical distribution of INL of the device.

[图 10-1](#) shows the INL distribution for a set of DAC11001B devices before the PCB assembly process. Exposing the devices to a JEDEC-standard thermal profile for reflow soldering produces the histogram shown in [图 10-2](#) on another set of devices. The standard INL deviation increased due to the thermal stress imparted to the device from the reflow process. However, baking DAC11001B units for 60 minutes at 125°C after the reflow soldering process produced the distribution given in [图 10-3](#). The post-reflow bake restored the INL standard deviation to pre-assembly levels.

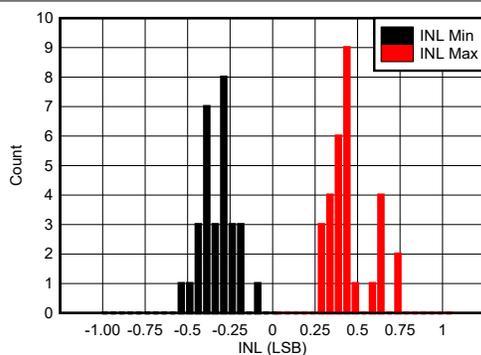

图 10-1. Typical INL Distribution Before Reflow Soldering

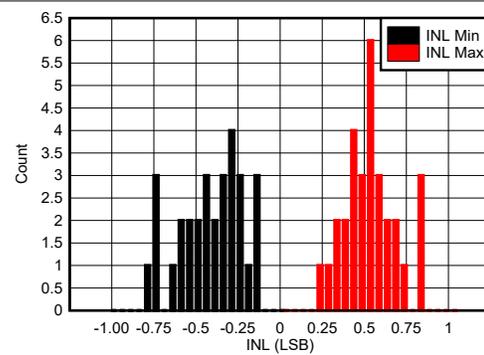

图 10-2. Typical INL Distribution After Reflow Soldering

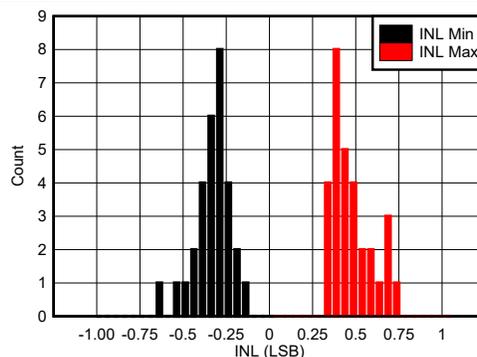

图 10-3. Typical INL Distribution Post-Reflow Units Baked at 125°C for 60 Minutes

11.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

(1) **Status:** For more details on status, see our [product life cycle](#).

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
