

## ISO154x-Q1 低功耗双向 I<sup>2</sup>C 隔离器

### 1 特性

- 符合汽车应用要求
- 具有符合 AEC-Q100 标准的下列特性：
  - 器件温度等级 1：-40°C 至 +125°C 的工作环境温度范围
  - 器件 HBM ESD 分类等级 3A
  - 器件 CDM ESD 分类等级 C6
- 提供功能安全
  - 可帮助进行功能安全系统设计的文档：  
[ISO1540-Q1, ISO1541-Q1](#)
- 隔离式双向 I<sup>2</sup>C 兼容型通信
- 支持高达 1MHz 的工作频率
- 3V 至 5.5V 电源电压范围
- 开漏输出，1 侧灌电流为 3.5mA，而 2 侧灌电流为 35mA
- ±50kV/μs 瞬态抗扰度（典型值）
- 安全相关认证：
  - 符合 DIN EN IEC 60747-17 (VDE 0884-17) 标准的 4242V<sub>PK</sub> 隔离
  - 符合 UL 1577 标准且持续时长为 1 分钟的 2500V<sub>RMS</sub> 隔离
  - 根据 IEC 62368-1 终端设备标准，获得 CSA 认证
  - 根据 GB4943.1-2011 标准，实现 CQC 基本绝缘

### 2 应用

- 电动和混合动力汽车
- 隔离式 I<sup>2</sup>C 总线
- SMBus 和 PMBus 接口
- 开漏网络
- 电机控制系统
- 电池管理
- I<sup>2</sup>C 电平转换

### 3 说明

ISO1540-Q1 和 ISO1541-Q1 器件均为兼容 I<sup>2</sup>C 接口的低功耗双向隔离器。凭借德州仪器 (TI) 电容隔离技术使用，这些器件的逻辑输入和输出缓冲器由二氧化硅 (SiO<sub>2</sub>) 绝缘栅进行隔离。与隔离式电源搭配使用时，这些器件可阻断高电压、隔离接地并防止噪声电流进入本地接地端，以至于干扰或损坏敏感电路。

与光电耦合器相比，这项隔离技术在功能、性能、尺寸、功耗方面具有一定优势。ISO1540-Q1 和 ISO1541-Q1 器件支持将一个完全隔离的 I<sup>2</sup>C 接口融入小型封装中。

ISO1540-Q1 具有两条隔离式双向通道，分别应用于时钟和数据线，而 ISO1541-Q1 具有一条双向数据通道和一条单向时钟通道。ISO1541-Q1 在具有一个控制器的应用中非常实用，ISO1540-Q1 适用于多控制器应用。对于目标可能需要时钟延展的应用，应使用 ISO1540-Q1 器件。

这些器件通过将 1 侧低电平输出电压偏移至高于 1 侧高电平输入电压的方式实现隔离式双向通信，从而避免标准数字隔离器发生内部逻辑锁存。

| T <sub>stg</sub> Storage temperature             |            | - 65  | 150                       | °C   |

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) All voltage values here within are with respect to the local ground pin (GND1 or GND2) and are peak voltage values.
- (3) Maximum voltage must not exceed 6 V.

### 6.2 ESD Ratings

|  |   |                          | VALUE | UNIT |
|--|---|--------------------------|-------|------|
| V <sub>(ESD)</sub> Electrostatic discharge | Human-body model (HBM), per AEC Q100-002 <sup>(1)</sup> | All pins except bus pins | ±4000 | V    |

- (1) Creepage and clearance requirements should be applied according to the specific equipment isolation standards of an application. Care should be taken to maintain the creepage and clearance distance of a board design to ensure that the mounting pads of the isolator on the printed-circuit board do not reduce this distance. Creepage and clearance on a printed-circuit board become equal in certain cases. Techniques such as inserting grooves and/or ribs on a printed circuit board are used to help increase these specifications.
- (2) This coupler is suitable for *basic electrical insulation* only within the maximum operating ratings. Compliance with the safety ratings shall be ensured by means of suitable protective circuits.
- (3) Apparent charge is electrical discharge caused by a partial discharge (pd).
- (4) All pins on each side of the barrier tied together creating a two-terminal device

## 6.8 Safety Limiting Values

Safety limiting intends to minimize potential damage to the isolation barrier upon failure of input or output circuitry. A failure of the I/O can allow low resistance to ground or the supply and, without current limiting, dissipate sufficient power to overheat the die and damage the isolation barrier, potentially leading to secondary system failures.

| PARAMETER  | TEST CONDITIONS   | MIN | TYP | MAX | UNIT |
|--|---|-----|-----|-----|------|
| I <sub>S</sub> Safety input, output, or supply current | R <sub>θJA</sub> = 114.6°C/W, V <sub>I</sub> = 5.5 V, T <sub>J</sub> = 150°C, T <sub>A</sub> = 25°C, see <a href="#">Figure 6-1</a> |     |     | 198 | mA   |
|  | R <sub>θJA</sub> = 114.6°C/W, V <sub>I</sub> = 3.6 V, T <sub>J</sub> = 150°C, T <sub>A</sub> = 25°C, see <a href="#">Figure 6-1</a> |     |     | 303 |      |
| T <sub>S</sub> Safety temperature                      |   |     |     | 150 | °C   |

The safety-limiting constraint is the maximum junction temperature specified in the data sheet. The power dissipation and junction-to-air thermal impedance of the device installed in the application hardware determines the junction temperature. The assumed junction-to-air thermal resistance in the [Table 6.4](#) is that of a device installed on a high-K test board for leaded surface-mount packages. The power is the recommended maximum input voltage times the current. The junction temperature is then the ambient temperature plus the power times the junction-to-air thermal resistance.

- (1) This parameter does not apply to the ISO1541-Q1 SCL1 line as it is unidirectional.
- (2)  $\Delta V_{OIT1} = V_{OL1} - V_{IHT1}$ . This represents the minimum difference between a Low-Level Output Voltage and a High-Level Input Voltage Threshold to prevent a permanent latch condition that would otherwise exist with bidirectional communication.
- (3) Any VCC voltages, on either side, less than the minimum will ensure device lockout. Both VCC voltages greater than the maximum will prevent device lockout.

## 7 Detailed Description

### 7.1 Overview

The I<sup>2</sup>C bus is used in a wide range of applications because it is simple to use. The bus consists of a two-wire communication bus that supports bidirectional data transfer between a controller device and several target devices. The controller, or processor, controls the bus, specifically the serial clock (SCL) line. Data is transferred between the controller and target through a serial data (SDA) line. This data can be transferred in four speeds: standard mode (0 to 100 kbps), fast mode (0 to 400 kbps), fast-mode plus (0 to 1 Mbps), and high-speed mode (0 to 3.4 Mbps). The most common speeds are the standard and fast modes.

The I<sup>2</sup>C bus operates in bidirectional, half-duplex mode, while standard digital isolators are unidirectional devices. To make efficient use of one technology supporting the other, external circuitry is required that separates the bidirectional bus into two unidirectional signal paths without introducing significant propagation delay. These devices have their logic input and output buffers separated by TI's capacitive isolation technology using a silicon dioxide (SiO<sub>2</sub>) barrier. When used in conjunction with isolated power supplies, these devices block high voltages, isolate grounds, and prevent noise currents from entering the local ground and interfering with or damaging sensitive circuitry.

### 7.4 Isolator Functional Principle

To isolate a bidirectional signal path (SDA or SCL), the ISO1540-Q1 internally splits a bidirectional line into two unidirectional signal lines, each of which is isolated through a single-channel digital isolator. Each channel output is made open-drain to comply with the open-drain technology of I<sup>2</sup>C. Side 1 of the ISO1540-Q1 connects to a low-capacitance I<sup>2</sup>C node, while side 2 is designed for connecting to a fully loaded I<sup>2</sup>C bus with up to 400 pF of capacitance.

图 7-3. SDA Channel Design and Voltage Levels at SDA1

At first sight, the arrangement of the internal buffers suggests a closed signal loop that is prone to latch-up. However, this loop is broken by implementing an output buffer (B) whose output low-level is raised by a diode drop to approximately 0.75 V, and the input buffer (C) that consists of a comparator with defined hysteresis. The

comparator's upper and lower input thresholds then distinguish between the proper low-potential of 0.4 V (maximum) driven directly by SDA1 and the buffered output low-level of B.

图 7-4 demonstrate the switching behavior of the I<sup>2</sup>C isolator, ISO1540-Q1, between a controller node at SDA1 and a heavy loaded bus at SDA2.

图 7-4. SDA Channel Timing in Receive and Transmit Directions

### 7.4.1 Receive Direction (Left Diagram of)

When the I<sup>2</sup>C bus drives SDA2 low, SDA1 follows after a certain delay in the receive path. The output low is the buffered output of  $V_{OL1} = 0.75\text{ V}$ , which is sufficiently low to be detected by Schmitt-trigger inputs with a minimum input-low voltage of  $V_{IL} = 0.9\text{ V}$  at 3 V supply levels.

When SDA2 is released, its voltage potential increases towards  $V_{CC2}$  following the time-constant formed by  $R_{PU2}$  and  $C_{bus}$ . After the receive delay, SDA1 is released and also rises towards  $V_{CC1}$ , following the time-constant  $R_{PU1} \times C_{node}$ . Because of the significant lower time-constant, SDA1 may reach  $V_{CC1}$  before SDA2 reaches  $V_{CC2}$  potential.

### 7.4.2 Transmit Direction (Right Diagram of)

When a controller drives SDA1 low, SDA2 follows after a certain delay in the transmit direction. When SDA2 turns low it also causes the output of buffer B to turn low but at a higher 0.75 V level. This level cannot be observed immediately as it is overwritten by the lower low-level of the controller.

However, when the controller releases SDA1, the voltage potential increases and first must pass the upper input threshold of the comparator,  $V_{IHT1}$ , to release SDA2. SDA1 then increases further until it reaches the buffered output level of  $V_{OL1} = 0.75\text{ V}$ , maintained by the receive path. When comparator C turns high, SDA2 is released after the delay in transmit direction. It takes another receive delay until B's output turns high and fully releases SDA1 to move toward  $V_{CC1}$  potential.

## 8 Application and Implementation

### 备注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 8.1 Application Information

#### 8.1.1 I<sup>2</sup>C Bus Overview

The inter-integrated circuit (I<sup>2</sup>C) bus is a single-ended, multi-controller, 2-wire bus for efficient inter-IC communication in half-duplex mode.

I<sup>2</sup>C uses open-drain technology, requiring two lines, serial data (SDA) and serial clock (SCL), to be connected to VDD by resistors (see [图 8-1](#)). Pulling the line to ground is considered a logic zero while letting the line float is a logic one. This logic is used as a channel access method. Transitions of logic states must occur while the SCL pin is low. Transitions while the SCL pin is high indicate START and STOP conditions. Typical supply voltages are 3.3 V and 5 V, although systems with higher or lower voltages are allowed.

图 8-1. I<sup>2</sup>C Bus

I<sup>2</sup>C communication uses a 7-bit address space with 16 reserved addresses, so a theoretical maximum of 112 nodes can communicate on the same bus. In praxis, however, the number of nodes is limited by the specified, total bus capacitance of 400 pF, which restricts communication distances to a few meters.

The specified signaling rates for the ISO1540-Q1 and ISO1541-Q1 devices are 100 kbps (standard mode), 400 kbps (fast mode), 1 Mbps (fast mode plus).

The bus has two roles for nodes: controller and target. A controller node issues the clock and target addresses, and also initiates and ends data transactions. A target node receives the clock and addresses and responds to requests from the controller. [图 8-2](#) shows a typical data transfer between controller and target.

**图 8-2. Timing Diagram of a Complete Data Transfer**

The controller initiates a transaction by creating a START condition, following by the 7-bit address of the target it wishes to communicate with. This is followed by a single read and write (R/W) bit, representing whether the controller wishes to write to 0, or to read from 1 the target. The controller then releases the SDA line to allow the target to acknowledge the receipt of data.

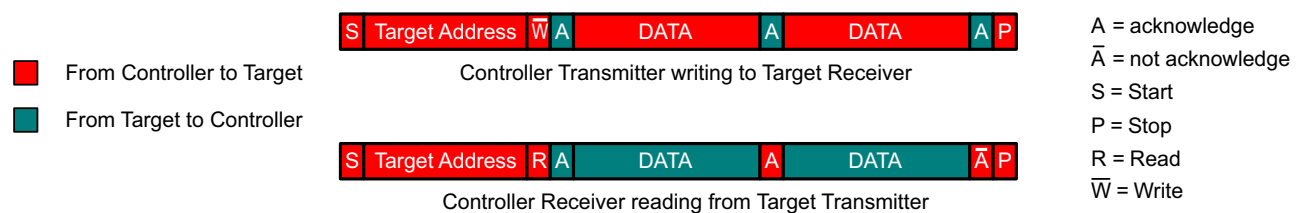

The target responds with an acknowledge bit (ACK) by pulling the SDA pin low during the entire high time of the 9th clock pulse on the SCL signal, after which the controller continues in either transmit or receive mode (according to the R/W bit sent), while the target continues in the complementary mode (receive or transmit, respectively).

The address and the 8-bit data bytes are sent most significant bit (MSB) first. The START bit is indicated by a high-to-low transition of SDA while SCL is high. The STOP condition is created by a low-to-high transition of SDA while SCL is high.

If the controller writes to a target, it repeatedly sends a byte with the target sending an ACK bit. In this case, the controller is in controller-transmit mode and the target is in target-receive mode.

If the controller reads from a target, it repeatedly receives a byte from the target, while acknowledging (ACK) the receipt of every byte but the last one (see 图 8-3). In this situation, the controller is in controller-receive mode and the target is in target-transmit mode.

The controller ends the transmission with a STOP bit, or may send another START bit to maintain bus control for further transfers.

**图 8-3. Transmit or Receive Mode Changes During a Data Transfer**

When writing to a target, a controller mainly operates in transmit-mode and only changes to receive-mode when receiving acknowledgment from the target.

When reading from a target, the controller starts in transmit-mode and then changes to receive-mode after sending a READ request (R/W bit = 1) to the target. The target continues in the complementary mode until the end of a transaction.

**备注**

The controller ends a reading sequence by not acknowledging (NACK) the last byte received. This procedure resets the target state machine and allows the controller to send the STOP command.

## 8.2 Typical Application

图 8-4 shows isolated I<sup>2</sup>C data acquisition system built with TI microcontroller, analog-to-digital converter, and I<sup>2</sup>C isolator, ISO1541-Q1.

The entire circuit operates from a single 3.3-V supply. A low-power push-pull converter, SN6501-Q1, drives a center-tapped transformer with an output that is rectified and linearly regulated to provide a stable 5-V supply for the data converter.

图 8-4. Isolated I<sup>2</sup>C Data Acquisition System

### 8.2.1 Design Requirements

The recommended power supply voltages (VCC1 and VCC2) must be from 3 V to 5.5 V. A recommended decoupling capacitor with a value of 0.1 µF is required between both the VCC1 and GND1 pins, and the VCC2 and GND2 pins to support of power supply voltages transient and to ensure reliable operation at all data rates.

### 8.2.2 Detailed Design Procedure

The power-supply capacitor with a value of 0.1-µF must be placed as close to the power supply pins as possible. The recommended placement of the capacitors must be 2-mm maximum from input and output power supply pins (VCC1 and VCC2).

The maximum load permissible on the input lines, SDA1 and SCL1, is  $\leq 40$  pF and on the output lines, SDA2 and SCL2, is  $\leq 400$  pF.

The minimum pullup resistors on the input lines, SDA1 and SCL1 to VCC1 must be selected in such a way that input current drawn is  $\leq 3.5$  mA. The minimum pullup resistors on the input lines, SDA2 and SCL2, to VCC2 must be selected in such a way that output current drawn is  $\leq 35$  mA. The maximum pullup resistors on the

input lines (SDA1 and SCL1) to VCC1 and on output lines (SDA1 and SCL1) to VCC2, depends on the load and rise time requirements on the respective lines.

## 9 Power Supply Recommendations

To help ensure reliable operation at data rates and supply voltages, TI recommends connecting a 0.1- $\mu$ F bypass capacitor at the input and output supply pins (VCC1 and VCC2). The capacitors should be placed as close to the supply pins as possible. If only a single, primary-side power supply is available in an application, isolated power can be generated for the secondary-side with the help of a transformer driver such as TI's [SN6501-Q1](#) device. For such applications, detailed power supply design and transformer selection recommendations are available in [SN6501-Q1 Transformer Driver for Isolated Power Supplies](#) (SLLSEF3).

## 10 Layout

### 10.1 Layout Guidelines

A minimum of four layers is required to accomplish a low EMI PCB design (see [图 10-1](#)). Layer stacking should be in the following order (top-to-bottom): high-speed signal layer, ground plane, power plane and low-frequency signal layer.

- Routing the high-speed traces on the top layer avoids the use of vias (and the introduction of their inductances) and allows for clean interconnects between the isolator and the transmitter and receiver circuits of the data link.
- Placing a solid ground plane next to the high-speed signal layer establishes controlled impedance for transmission line interconnects and provides an excellent low-inductance path for the return current flow.
- Placing the power plane next to the ground plane creates additional high-frequency bypass capacitance of approximately 100 pF/in<sup>2</sup>.
- Routing the slower speed control signals on the bottom layer allows for greater flexibility as these signal links usually have margin to tolerate discontinuities such as vias.

If an additional supply voltage plane or signal layer is needed, add a second power or ground plane system to the stack to keep it symmetrical. This makes the stack mechanically stable and prevents it from warping. Also the power and ground plane of each power system can be placed closer together, thus increasing the high-frequency bypass capacitance significantly.

For detailed layout recommendations, see the [Digital Isolator Design Guide](#) (SLLA284)

#### 10.1.1 PCB Material

For digital circuit boards operating at less than 150 Mbps, (or rise and fall times greater than 1 ns), and trace lengths of up to 10 inches, use standard FR-4 UL94V-0 printed circuit board. This PCB is preferred over cheaper alternatives because of lower dielectric losses at high frequencies, less moisture absorption, greater strength and stiffness, and the self-extinguishing flammability-characteristics.
