4 修订历史记录

Changes from Revision D (April 2016) to Revision E	Page
• 已删除 删除了最后一个 特性 项目	1
• Deleted LMP8480-H row from <i>Device Comparison Table</i>	3
• Changed REFA to REFB and REFB to REFA for pins 6 and 7, respectively, in <i>Pin Functions</i> table	3
• Deleted NCQ column from <i>Thermal Information</i> table	4
• Changed bidirectional to unidirectional is description of Figure 22 in <i>Basic Connections</i> section	13

Changes from Revision C (September 2015) to Revision D	Page
• 更改了典型应用原理图: 调换了 RSN 和 RSP 标签	1
• Changed conditions of <i>Electrical Characteristics</i> table	5
• Added unit to R _{OUT} parameter in <i>Electrical Characteristics</i> table	5
• Changed first paragraph of <i>Overview</i> section	10

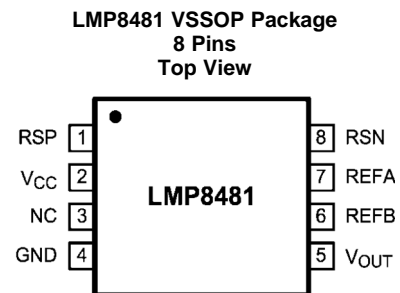

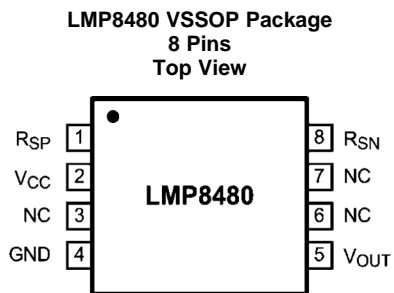

Changes from Revision B (December 2014) to Revision C	Page
• 已删除 删除了 LMP8480 和 LMP8481 的 WSON 封装选项	1
• Deleted -F version (50x gain) for LMP8480 and LMP8481	3
• Deleted WSON package options for LMP8480 and LMP8481	3

Changes from Revision A (August 2012) to Revision B	Page
• 已添加 引脚配置和功能部分, ESD 额定值表, 特性 说明 部分、器件功能模式、应用和实施部分、电源相关建议部分、布局部分、器件和文档支持部分以及机械、封装和可订购信息部分	1

5 Device Comparison Table

DEVICE NAME	GAIN	POLARITY
LMP8480-T	x20	Unidirectional
LMP8480-S	x60	Unidirectional
LMP8481-T	x20	Bidirectional or unidirectional
LMP8481-S	x60	Bidirectional or unidirectional
LMP8481-H	x100	Bidirectional or unidirectional

6 Pin Configuration and Functions

Pin Functions

PIN		I/O	DESCRIPTION	
NO.	NAME			
1	R _{SP}	I	Positive current sense input	
2	V _{CC}	P	Positive supply voltage	
3	NC	—	No connection – not internally connected	
4	GND	P	Ground	
5	V _{OUT}	O	Output	
6	NC or REFB	I	LMP8480: no connection	LMP8481: reference voltage “B” input
7	NC or REFA	I	LMP8480: no connection	LMP8481: reference voltage “A” input
8	R _{SN}	I	Negative current sense input	

7 Specifications

7.1 Absolute Maximum Ratings

 over operating free-air temperature range (unless otherwise noted)⁽¹⁾⁽²⁾⁽³⁾

		MIN	MAX	UNIT
Supply voltage (V_{CC} to GND)		–0.3	85	V
R_{SP} or R_{SN} to GND		–0.3	85	V
V_{OUT} to GND		–0.3 to the lesser of ($V_{CC} + 0.3$) or +20		V
V_{REF} pins (LMP8481 only)	Other V_{REF} pin tied to ground	–0.3	12	V
	Applied to both V_{REF} pins tied together	–0.3	6	
Differential input voltage		–85	85	V
Current into output pin		–20 ⁽⁴⁾	20	mA
Current into any other pins		–5 ⁽⁴⁾	5	mA
Operating temperature		–40	125	°C
Junction temperature		–40	150	°C
Storage temperature		–65	150	°C

- (1) The maximum power dissipation must be derated at elevated temperatures and is dictated by $T_{J(MAX)}$, θ_{JA} , and the ambient temperature, T_A . The maximum allowable power dissipation $P_{DMAX} = (T_{J(MAX)} - T_A) / \theta_{JA}$ or the number given in [Absolute Maximum Ratings](#), whichever is lower.
- (2) If Military/Aerospace specified devices are required, contact the Texas Instruments Sales Office/Distributors for availability and specifications.
- (3) Stresses beyond those listed under [Absolute Maximum Ratings](#) may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under [Recommended Operating Conditions](#) is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (4) When the input voltage (V_{IN}) at any pin exceeds power supplies ($V_{IN} < GND$ or $V_{IN} > V_S$), the current at that pin must not exceed 5 mA, and the voltage (V_{IN}) has to be within the [Absolute Maximum Ratings](#) for that pin. The 20-mA package input current rating limits the number of pins that can safely exceed the power supplies with current flow to four pins.

7.2 ESD Ratings

		VALUE	UNIT
$V_{(ESD)}$ Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±750	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

 Expected normal operating conditions over free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
Supply voltage (V _{CC})		4.5	76	V
Common mode voltage		4.0	76	V
Reference input (LMP8481 only)	V _{REFA} and V _{REFB} tied together	−0.3 to the lesser of (V _{CC} − 1.5) or +6		V
	Single V _{REF} pin with other V _{REF} pin grounded	−0.3 or +12 where the average of the two V _{REF} pins is less than the lesser of (V _{CC} − 1.5) or +6		

- (1) Exceeding the [Recommended Operating Conditions](#) for extended periods of time may effect device reliability or cause parametric shifts.

7.4 Thermal Information

THERMAL METRIC ⁽¹⁾		LMP8480, LMP8481	UNIT
		DGK (VSSOP)	
		8 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	185	°C/W

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

7.5 Electrical Characteristics

- (1) *Electrical Characteristics* table values apply only for factory testing conditions at the temperature indicated. Factory testing conditions result in very limited self-heating of the device such that $T_J = T_A$. **No** specification of parametric performance is indicated in the electrical tables under conditions of internal self-heating where $T_J > T_A$.
- (2) All limits are specified by testing, design, or statistical analysis.
- (3) Typical values represent the most likely parametric norm at the time of characterization. Actual typical values can vary over time and also depend on the application and configuration. The typical values are not tested and are not ensured on shipped production material.
- (4) Offset voltage temperature drift is determined by dividing the change in V_{OS} at the temperature extremes by the total temperature change.
- (5) Positive bias current corresponds to current flowing into the device.
- (6) This parameter is specified by design and/or characterization and is not tested in production.

Electrical Characteristics (continued)

unless otherwise specified, all limits specified for at $T_A = 25^\circ\text{C}$, $V_{CC} = 4.5\text{ V}$ to 76 V , $4.5\text{ V} \leq V_{CM} \leq 76\text{ V}$, $R_L = 100\text{ k}\Omega$, $V_{SENSE} = (V_{RSP} - V_{RSN}) = 0\text{ V}^{(1)}$

8 Detailed Description

8.1 Overview

The LMP8480 and LMP8481 are single-supply, high-side current sense amplifiers with available fixed gains of x20, x60 and x100. The power supply range is 4.5 V to 76 V, and the common-mode input voltage range is capable of 4.0-V to 76-V operation. The supply voltage and common-mode range are completely independent of each other, which causes the LMP848x supply voltage to be extremely flexible because the LMP848x supply voltage can be greater than, equal to, or less than the load source voltage, and allows the device to be powered from the system supply or the load supply voltage.

The LMP8480 and LMP8481 supply voltage does not have to be larger than the load source voltage. A 76-V load source voltage with a 5-V supply voltage is perfectly acceptable.

8.1.1 Theory of Operation

The LMP8480 and LMP8481 are comprised of two main stages. The first stage is a differential input current to voltage converter, followed by a differential voltage amplifier and level-shifting output stage. Also present is an internal 14-V low-dropout regulator (LDO) to power the amplifiers and output stage, as well as a reference divider resistor string to allow the setting of the reference level.

As [Figure 18](#) illustrates, the current flowing through R_{SENSE} develops a voltage drop called V_{SENSE} . The voltage across the sense resistor, V_{SENSE} , is then applied to the input R_{SP} and R_{SN} pins of the amplifier.

Internally, the voltage on each input pin is converted to a current by the internal precision thin-film input resistors R_{GP} and R_{GN} . A second set of much higher value V_{CM} sense resistors between the inputs provide a sample of the input common-mode voltage for internal use by the differential amplifier.

V_{SENSE} is applied to the differential amplifier through R_{GP} and R_{GN} . These resistors change the input voltage to a differential current. The differential amplifier then servos the resistor currents through the MOSFETs to maintain a zero balance across the differential amplifier inputs.

With no input signal present, the currents in R_{GP} and R_{GN} are equal. When a signal is applied to V_{SENSE} , the current through R_{GP} and R_{GN} are imbalanced and are no longer equal. The amplifier then servos the MOSFETs to correct this current imbalance, and the extra current required to balance the input currents is then reflected down into the two lower 400-k Ω tail resistors. The difference in the currents into the tail resistors is therefore proportional to the amplitude and polarity of V_{SENSE} . The tail resistors, being larger than the input resistors for the same current, then provide voltage gain by changing the current into a proportionally larger voltage. The gain of the first stage is then set by the tail resistor value divided by R_G value.

The differential amplifier stage then samples the voltage difference across the two 400-k Ω tail resistors and also applies a further gain-of-five and output level-shifting according to the applied reference voltage (V_{REF}).

The resulting output of the amplifier will be equal to the differential input voltage times the gain of the device, plus any voltage value applied to the two V_{REF} pins.

The resistor values in the schematic are ideal values for clarity and understanding. [Table 1](#) shows the actual values used that account for parallel combinations and loading. This table can be used for calculating the effects of any additional external resistance.

The LMP8480 is identical to the LMP8481, except that both the V_{REF} pins are grounded internally.

Table 1. Actual Internal Resistor Values

GAIN OPTION	R_{GP} AND R_{GN} (Each)	$R_{VCMSENSE}$ (Each)	R_{TAIL} (Each)	DIFFERENTIAL AMP FB (Each)	V_{REFX} RESISTORS (Each)
20x	98.38 k	491.9 k	393.52 k	1967.6 k	98.38 k
60x	32.793 k	172.165 k	393.52 k	1967.6 k	98.38 k
100x	19.676 k	98.38 k	393.52 k	1967.6 k	98.38 k

8.2 Functional Block Diagrams

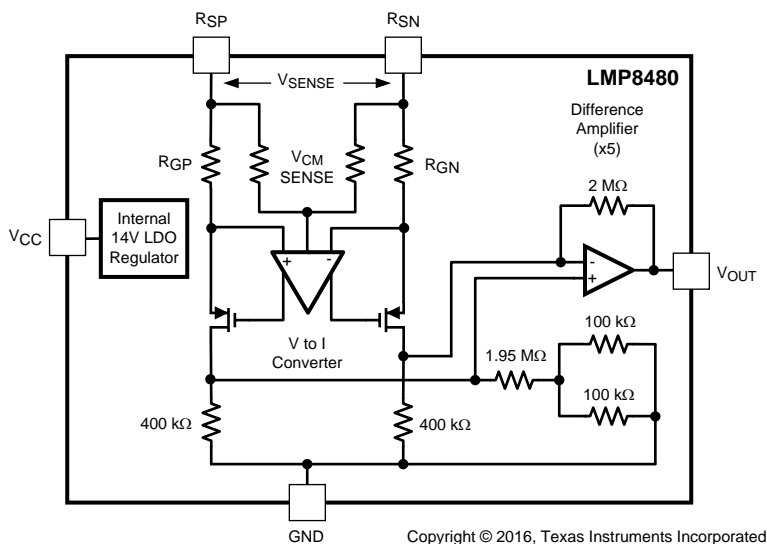

Figure 17. LMP8480 Block Diagram

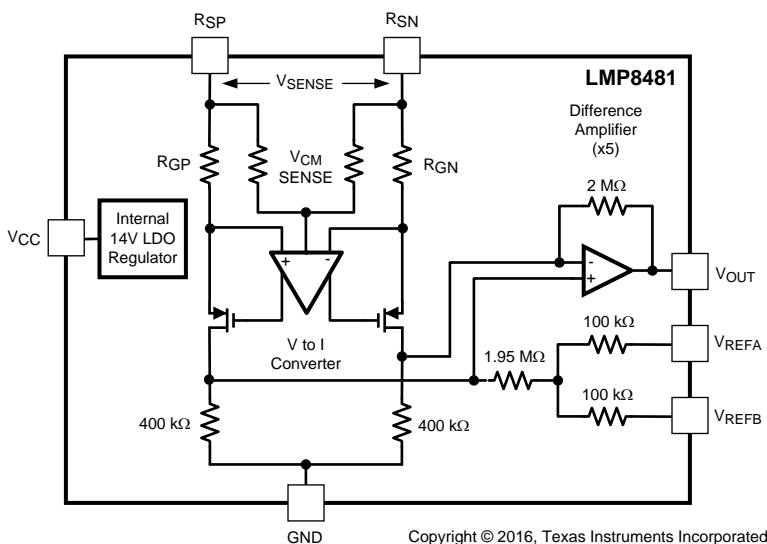

Figure 18. LMP8481 Block Diagram

8.3 Feature Description

8.3.1 Basic Connections

Figure 19 through Figure 22 show the basic connections for several different configurations.

Figure 19 shows the basic connections for the LMP8480 for unidirectional applications. The output is at zero with zero sense voltage.

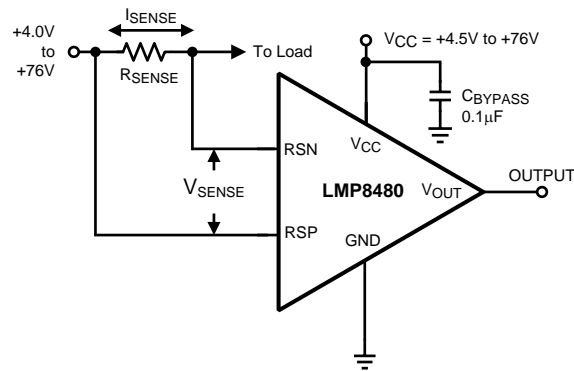

Figure 19. LMP8480 Basic Connections (Unidirectional)

Figure 20 shows the basic connections for the LMP8481 for bidirectional applications using an external reference input. At zero input voltage, the output is at the applied reference voltage (V_{REF}), moving positive or negative from the zero reference point.

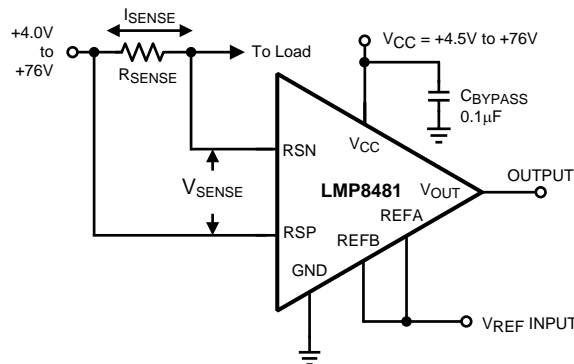

Figure 20. LMP8481 Basic Connections for External 1:1 V_{REF} Input (Bidirectional)

Figure 21 shows the basic connections for the LMP8481 for bidirectional applications centering the output at one-half the applied V_{REF} or V_{CC} voltage. If V_{REFA} is connected to V_{CC} , then the output zero point is $V_{CC} / 2$. If V_{REFA} is connected to the ADC V_{REF} line, then the zero output is at mid-scale for the ADC.

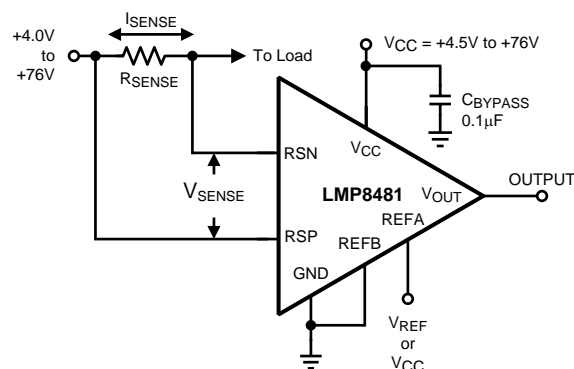

Figure 21. LMP8481 Basic Connections for Mid-Bias ($V_{REF} / 2$) Input (Bidirectional)

Feature Description (continued)

Figure 22 shows the how to connect the LMP8481 for unidirectional applications, thus making the LMP8481 equivalent to the LMP8480 in Figure 19.

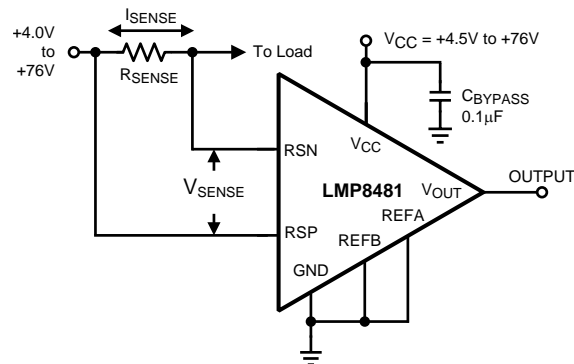

Figure 22. LMP8481 Connections for Unidirectional Configuration (Equivalent to LMP8480 Unidirectional)

8.3.2 Selection of the Sense Resistor

The accuracy of the current measurement depends heavily on the accuracy of the shunt resistor R_{SENSE} . The value of R_{SHUNT} depends on the application and is a compromise between small-signal accuracy, maximum permissible voltage drop, and allowable power dissipation in the current measurement circuit.

The use of a 4-terminal or Kelvin sense resistor is highly recommended; see the [Layout Guidelines](#) section.

For best results, the value of the resistor is calculated from the maximum expected load current I_{LMAX} and the expected maximum output swing V_{OUTMAX} , plus a few percent of headroom. See the [Maximum Output Voltage](#) section for details about the maximum output voltage limits.

High values of R_{SENSE} provide better accuracy at lower currents by minimizing the effects of amplifier offset. Low values of R_{SENSE} minimize load voltage loss, but at the expense of accuracy at low currents. A compromise between low current accuracy and load circuit losses must generally be made.

The maximum V_{SENSE} voltage that must be generated across the R_{SENSE} resistor is shown in Equation 1:

$$V_{SENSE} = V_{OUTMAX} / A_V \quad (1)$$

NOTE

The maximum V_{SENSE} voltage must be no more than 667 mV.

From this maximum V_{SENSE} voltage, the R_{SENSE} value can be calculated from Equation 2:

$$R_{SENSE} = V_{SENSE} / I_{LMAX} \quad (2)$$

Take care not exceed the maximum power dissipation of the resistor. The maximum sense resistor power dissipation is shown in Equation 3:

$$P_{RSENSE} = V_{SENSE} \times I_{LMAX} \quad (3)$$

Using a 2-3x minimum safety margin is recommended in selecting the power rating of the resistor.

8.3.3 Using PCB Traces as Sense Resistors

While it may be tempting to use a known length of PCB trace resistance as a sense resistor, it is not recommended.

The temperature coefficient of copper is typically 3300-4000 ppm/°K, and can vary over PCB process variations and require measurement correction (possibly requiring ambient temperature measurements).

A typical surface mount sense resistor tempco is in the 50 ppm to 500 ppm/°C range offering more measurement consistency and accuracy over the copper trace. Special low-tempco resistors are available in the 0.1 to 50 ppm range, but at a higher cost.

Feature Description (continued)

8.3.4 V_{REFA} and V_{REFB} Pins (LMP8481 Only)

The voltage applied to the V_{REFA} and V_{REFB} pins controls the output zero reference level. Depending on how the pins are configured, the output reference level can be set to GND, or $V_{\text{CC}} / 2$, or external $V_{\text{REF}} / 2$, or the average of two different input references.

The reference inputs consist of a pair of divider resistors with equal values to a common summing point, V_{REF}' , as shown in Figure 23. Assuming V_{SENSE} is zero, the output is at the same value as V_{REF}' .

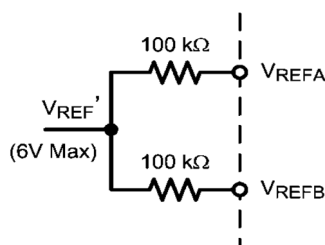

Figure 23. V_{REF} Input Resistor Network

V_{REF}' is the voltage at the resistor tap-point that is directly applied to the output as an offset. With the two V_{REF} inputs tied together, the output zero voltage has a 1:1 ratio relationship with V_{REF}' .

$$V_{\text{OUT}} = (V_{\text{RSP}} - V_{\text{RSN}}) \times A_v + V_{\text{REF}}' \quad (4)$$

Where:

$$V_{\text{REF}}' = V_{\text{REFA}} = V_{\text{REFB}} \text{ (Equal Inputs)} \quad (5)$$

or:

$$V_{\text{REF}}' = (V_{\text{REFA}} + V_{\text{REFB}}) / 2 \text{ (Different Inputs)} \quad (6)$$

8.3.4.1 One-to-One (1:1) Reference Input

To directly set the reference level, the two inputs are connected to the external reference voltage. The applied V_{REF} is reflected 1:1 on the output, as shown in Figure 24.

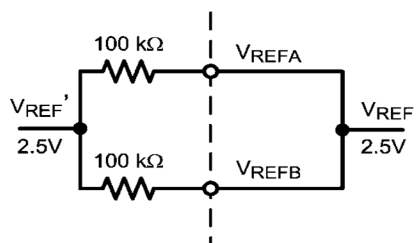

Figure 24. Applying 1:1 Direct Reference Voltage

Feature Description (continued)

8.3.4.2 Setting Output to One-Half V_{CC} or external V_{REF}

For mid-range operation, V_{REFB} must be tied to ground and V_{REFA} can be tied to V_{CC} or an external A/D reference voltage. The output is set to one-half the reference voltage. For example, a 5-V reference results in a 2.5-V output zero reference.

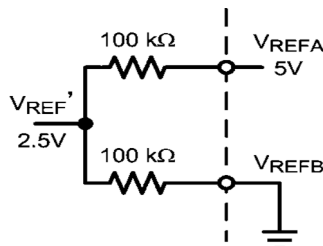

Figure 25. Applying a Divided Reference Voltage

$$V_{REF'} = (V_{REFA} - V_{REFB}) / 2 \quad (7)$$

When the reference pins are biased at different voltages, the output is referenced to the average of the two applied voltages.

The reference pins must always be driven from clean, stable sources, such as A/D reference lines or clean supply lines. Any noise or drifts on the reference inputs are directly reflected in the output. Take care if the power supply is used as the reference source so as to not introduce supply noise, drift or sags into the measurement.

Different resistor divider ratios can be set by adding external resistors in series with the internal 100-kΩ resistors, though the temperature coefficient (tempco) of the external resistors may not tightly track the internal resistors and there are slight errors over temperature.

The LMP8480 is identical to the LMP8481, except that both the V_{REF} pins are grounded internally. The LMP8481 can replace the LMP8480 if both V_{REF} pins are grounded.

8.3.5 Reference Input Voltage Limits (LMP8481 Only)

The maximum voltage on either reference input pin is limited to V_{CC} or 12 V, whichever is less.

The average voltage on the two V_{REF} pins, and thus the actual output reference voltage level, is limited to a maximum of 1.5 V below V_{CC} , or 6 V, whichever is less. Beware that supply voltages of less than 7.5 V have a diminishing V_{REF} maximum.

Both V_{REFA} and V_{REFB} can both be grounded to provide a ground referenced output (thus functionally duplicating the LMP8480).

Note that there can be a dynamic error in the V_{REF} to output level matching of up to 100 $\mu V/V$. Normally this error is not an issue for fixed references, but if the reference voltage is dynamically adjusted during operation, this error must be taken into account during calibration routines. This error varies in both amplitude and polarity part-to-part, but the slope is generally linear.

8.3.6 Low-Side Current Sensing

The LMP8480 and LMP8481 are not recommended for low-side current sensing at ground level. The voltage on either input pin must be a minimum of 4.0 V above the ground pin for proper operation. The output level may not be valid for common-mode voltages below 4 V. This minimum voltage requirement must be taken into consideration for monitoring or feedback applications where the load-supply voltage can dip below 4 V or be switched completely off.

Feature Description (continued)

8.3.7 Input Series Resistance

Because the input stage uses precision resistors to convert the voltage on the input pin to a current, any resistance added in series with the input pins changes the gain. If a resistance is added in series with an input, the gain of that input does not track that of the other input, causing a constant gain error.

TI does not recommend using external resistances to alter the gain because external resistors do not have the same thermal matching as the internal thin film resistors.

If resistors are purposely added for filtering, resistance must be added equally to both inputs and the user must be aware that the gain changes slightly. See the end of the [Theory of Operation](#) section for the internal resistor values. External resistances must be kept below 10 Ω .

8.3.8 Minimum Output Voltage

The amplifier output cannot swing to exactly 0 V. There is always a minimum output voltage set by the output transistor saturation and input offset errors. This voltage creates a minimum output swing around the zero current reading resulting from the output saturation. The user must be aware of this output swing when designing any servo loops or data acquisition systems that may assume 0 V = 0 A. If a true zero is required, use the LMP8481 with a VREF set slightly above ground (> 50 mV); see the [Swinging Output Below Ground](#) section for a possible solution to this issue.

8.3.9 Swinging Output Below Ground

If a negative supply is available, a pulldown resistor can be added from the output to the negative voltage to allow the output to swing a few millivolts below ground. Adding a pulldown resistor allows the ADC to resolve true zero and recover codes that normally are lost to the negative output saturation limit.

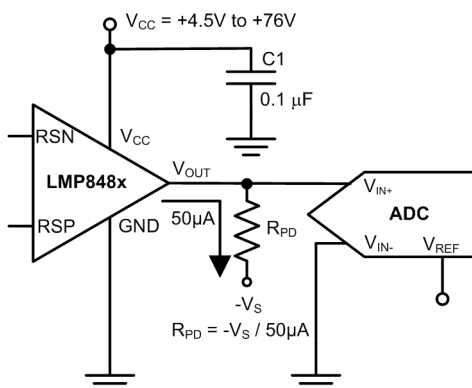

Figure 26. Output Pulldown Resistor Example

A minimum of 50 μ A must be sourced (pulled) from the output to a negative voltage. The pulldown resistor can be calculated from:

$$R_{PD} = -V_S / 50 \mu A \quad (8)$$

For example, if a -5-V supply is available, use a pulldown resistor of 5 V / 50 μ A = 100 k Ω . Adding this resistor allows the output to swing to approximately 10 mV below ground.

This technique can also reduce the maximum positive swing voltage. Do not forget to include the parallel loading effects of the pulldown any output load. Exceeding -100 mV on the output is not recommended. Source currents greater than 100 μ A must be avoided to prevent self-heating at high-supply voltages. Pulldown resistor values must not be so low as to heavily load the output during positive output excursions. This mode of operation is not directly specified and is not ensured.

Feature Description (continued)

8.3.10 Maximum Output Voltage

The LMP8481 has an internal precision 14-V low-dropout regulator that limits the maximum amplifier output swing to approximately 250 mV below V_{CC} or 13.7 V (whichever is less). This regulator effectively clamps the maximum output to slightly less than 13.7 V even with a V_{CC} greater than 14 V; see [Typical Application With a Resistive Divider](#) section for more information.

8.4 Device Functional Modes

8.4.1 Unidirectional vs Bidirectional Operation

Unidirectional operation is where the load current only flows in one direction (V_{SENSE} is always positive). Application examples are PA monitoring, non-inductive load monitoring, and laser or LED drivers. Unidirectional operation allows the output zero reference to be true zero volts on the output. The LMP8480 is designed for unidirectional applications where the setting of VREF is not required; see the [Unidirectional Application With the LMP8480](#) section for more details.

Bidirectional operation is where the load current can flow in both directions (V_{SENSE} can be positive or negative). Application examples are battery-charging or regenerative motor monitoring. The LMP8481 is designed for bidirectional applications and has a pair of VREF pins to allow the setting of the output zero reference level (V_{REF}); see the [Unidirectional Application With the LMP8480](#) section for more details.

9 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The LMP848x amplifies the voltage developed across a current-sensing resistor when current passes through it. Flexible offset inputs allow adjusting the functionality of the output for multiple configurations, as discussed throughout this section.

9.1.1 Input Common-Mode and Differential Voltage Range

The input common-mode range, where common-mode range is defined as the voltage from ground to the voltage on R_{SP} input, must be in the range of 4.0 V to 76 V. Operation below 4.0 V on either input pin introduces severe gain error and nonlinearities.

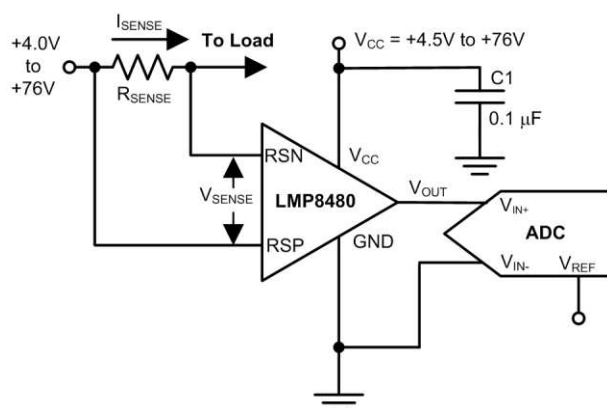

The maximum differential voltage (defined as the voltage difference between R_{SP} and R_{SN}) must be 667 mV or less. The theoretical maximum input is 700 mV ($14\text{ V} / 20$).

Taking the inputs below 4 V does not damage the device, but the output conditions during this time are not predictable and are not ensured.

If the load voltage (V_{cm}) is expected to fall below 4 V as part of normal operation, preparations must be made for invalid output levels during this time.

9.2 Typical Applications

9.2.1 Unidirectional Application With the LMP8480

Copyright © 2016, Texas Instruments Incorporated

Figure 27. Unidirectional Application with the LMP8480

9.2.1.1 Design Requirements

The LMP8480 is designed for unidirectional current sense applications. The output of the amplifier is equal to the differential input voltage times the fixed device gain.

9.2.1.2 Detailed Design Procedure

The output voltage can be calculated from [Equation 9](#):

$$V_{OUT} = (V_{RSP} - V_{RSN}) \times A_v \quad (9)$$

Typical Applications (continued)

Note that the minimum zero reading is limited by the lower output swing and input offset. The LMP8480 is functionally identical to the LMP8481, but with the V_{REFA} and V_{REFB} nodes grounded internally. The LMP8481 can replace the LMP8480 if both the V_{REF} inputs (pins 6 and 7) are grounded.

9.2.1.3 Application Curve

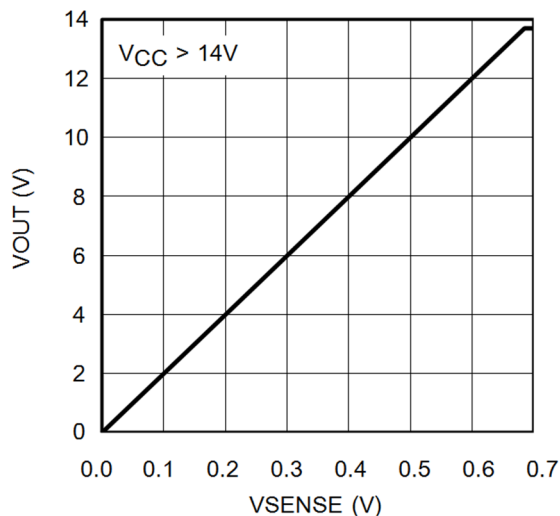

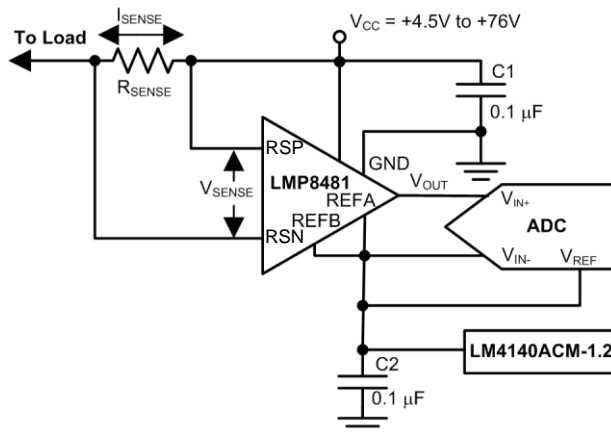

Figure 28. Unidirectional Transfer Function for Gain-of-20 Option

9.2.2 Bidirectional Current Sensing Using the LMP8481

Copyright © 2016, Texas Instruments Incorporated

Figure 29. Bidirectional Current Sensing Using the LMP8481

9.2.2.1 Design Requirements

Bidirectional operation is required where the measured load current can be positive or negative. Because V_{SENSE} can be positive or negative, and the output cannot swing negative, the zero output level must be level-shifted above ground to a known zero reference point. The LMP8481 allows for the setting this reference point.

Typical Applications (continued)

9.2.2.2 Detailed Design Procedure

The V_{REFA} and V_{REFB} pins set the zero reference point. The output zero reference point is set by applying a voltage to the REFA and REFB pins; see the [Unidirectional Application With the LMP8480](#) section. The [V_{REFA} and V_{REFB} Pins \(LMP8481 Only\)](#) section describes the output transfer function with a 1.2-V reference applied to the gain-of-20 option.

9.2.2.3 Application Curve

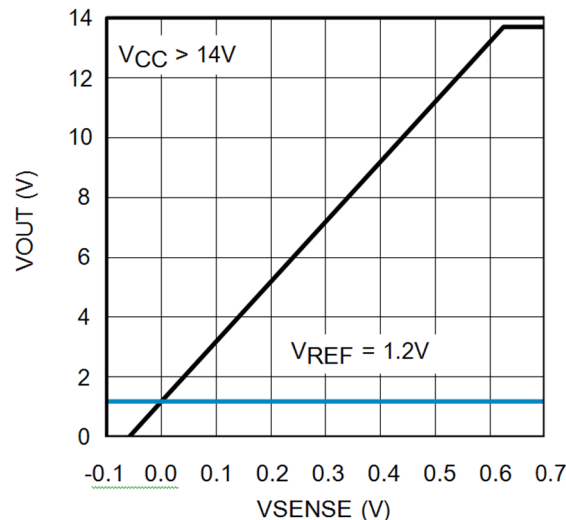

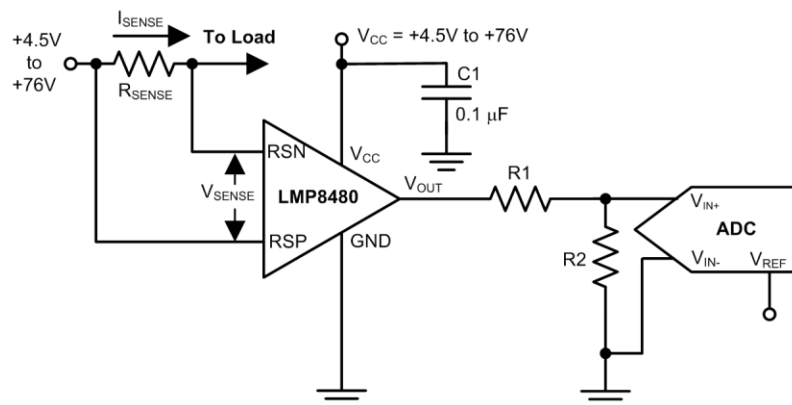

Figure 30. Bidirectional Transfer Function Using a 1.2-V Reference Voltage

9.2.3 Typical Application With a Resistive Divider

Take care if the output is driving an A/D input with a maximum A/D maximum input voltage lower than the amplifier supply voltage because the output can swing higher than the planned load maximum resulting from input transients or shorts on the load and overload or possibly damage the A/D input.

A resistive attenuator, as shown in [Figure 31](#), can be used to match the maximum swing to the input range of the A/D converter.

Figure 31. Typical Application With Resistive Divider Example

10 Power Supply Recommendations

10.1 Power Supply Decoupling

In order to decouple the LMP848x from ac noise on the power supply, TI recommends using a 0.1- μ F bypass capacitor between the V_{CC} and GND pins. This capacitor must be placed as close as possible to the supply pins. In some cases, an additional 10- μ F bypass capacitor can further reduce the supply noise.

Do not forget that these bypass capacitors must be rated for the full supply and load source voltage. TI recommends that the working voltage of the capacitor (WVDC) be at least two times the maximum expected circuit voltage.

11 Layout

11.1 Layout Guidelines

The traces leading to and from the sense resistor can be significant error sources. With small value sense resistors ($< 100\text{ m}\Omega$), any trace resistance shared with the load current can cause significant errors.

The amplifier inputs must be directly connected to the sense resistor pads using Kelvin or 4-wire connection techniques. The traces must be one continuous piece of copper from the sense resistor pad to the amplifier input pin pad, and ideally on the same copper layer with minimal vias or connectors. These recommendations can be important around the sense resistor if any significant heat gradients are being generated.

To minimize noise pickup and thermal errors, the input traces must be treated as a differential signal pair and routed tightly together with a direct path to the input pins. The input traces must be run away from noise sources, such as digital lines, switching supplies or motor drive lines. Remember that these traces can contain high voltage, and must have the appropriate trace routing clearances.

Because the sense traces only carry the amplifier bias current (approximately 7 μ A at room temperature), the connecting input traces can be thinner, signal level traces. Excessive resistance in the trace must also be avoided.

The paths of the traces must be identical, including connectors and vias, so that these errors are equal and cancel.

The sense resistor heats up when the load increases. When the resistor heats up, the resistance generally goes up, which causes a change in the readings. The sense resistor must have as much heatsinking as possible to remove this heat through the use of heatsinks or large copper areas coupled to the resistor pads. A reading drifting over time after turn-on can usually be traced back to sense resistor heating.

11.2 Layout Example

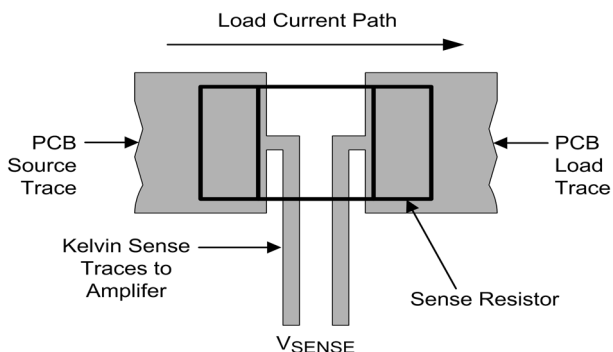

Figure 32. Kelvin or 4-Wire Connection to the Sense Resistor

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

(2) Material type: When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) RoHS values: Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

(4) Lead finish/Ball material: Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) MSL rating/Peak reflow: The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) Part marking: There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

4214862/A 04/2023

NOTES: (continued)

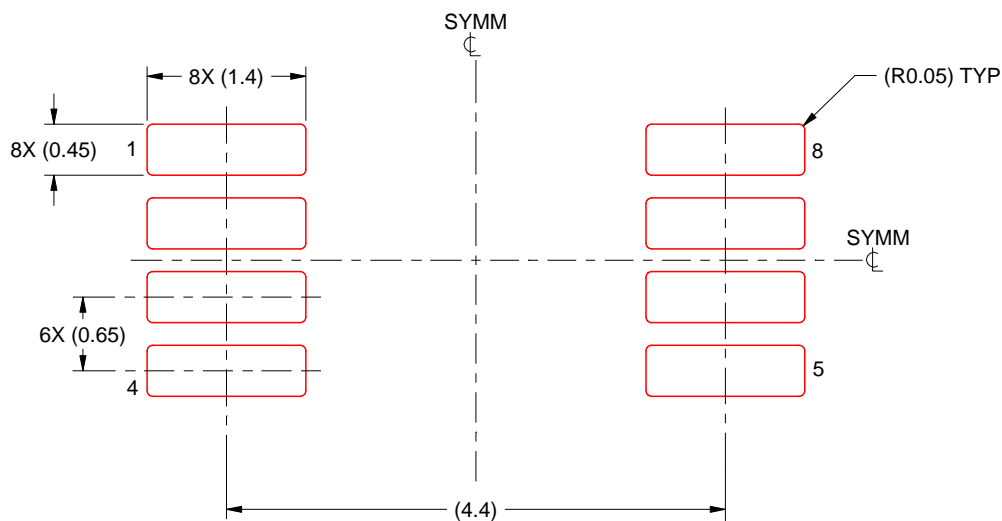

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.
9. Size of metal pad may vary due to creepage requirement.
