TPA6120A2 High Fidelity Headphone Amplifier

1 Features

- SNR of 128dB A-Weighted.
- THD of 112.5dB
- Current-Feedback Architecture
- Output Voltage Noise of 0.9μV_{rms} at Gain = 1V/V (16Ω Load)
- Power Supply Range: ±5V to ±15V
- 1300V/µs Slew Rate
- Can be configured for Single Ended or Differential Inputs
- Independent Power Supplies for Low Crosstalk

2 Applications

- Professional Audio Equipment
- HiFi Smartphone
- Consumer Home Audio Equipment
- Headphone Drivers

3 Description

In applications requiring a high-power output, very high fidelity headphone amplifier, the TPA6120A2 replaces a costly discrete design and allows music, not the amplifier, to be heard. The TPA6120A2's current-feedback AB amplifier architecture delivers high bandwidth, extremely low noise, and up to 128dB of dynamic range.

Three key features make current-feedback amplifiers outstanding for audio. The first feature is the high slew rate that prevents odd order distortion anomalies. The second feature is current-on-demand at the output that enables the amplifier to respond quickly and linearly when necessary without risk of output distortion. When large amounts of output power are suddenly needed, the amplifier can respond extremely quickly without raising the noise floor of the system and degrading the signal-to-noise ratio. The third feature is the gain-independent frequency response that allows the full bandwidth of the amplifier to be used over a wide range of gain settings.

Device Information(1)

PART NUMBER	PACKAGE	BODY SIZE (NOM)
TPA6120A2	HSOP (20)	7.5mm x 12.82mm
	VQFN (14)	3.5mm x 3.5mm

(1) For all available packages, see the orderable addendum at the end of the datasheet.

Table of Contents

5 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision A (July 2014) to Revision B — **Page**

- Changed the Device Information Packages From: DWP (20) and RGY (14) To: HSOP (20) and VQFN (14) ... 1
- Changed QFN to VQFN in the Pin Functions table ... 3
- Added a NOTE to the Applications and Implementation section ... 9
- Added Title: Application Information ... 9
- Deleted Title: Application Circuit ... 9
- Changed the *Design Requirements* ... 10
- Deleted Title: Application Circuit ... 14
- Moved two paragraphs following Figure 19 to proceed Figure 19 ... 14

Changes from Original (March 2004) to Revision A — **Page**

- Changed Added *ESD Rating* table, *Feature Description* section, *Device Functional Modes*, *Application and Implementation* section, *Power Supply Recommendations* section, *Layout* section, *Device and Documentation Support* section, and *Mechanical, Packaging*, and *Orderable Information* section ... 1
- Added the VQFN package information ... 1
- Updated Pin descriptions to clarify power supply. ... 3
- Lowered minimum V_{IC}(±5Vcc) From: ±3.6 To: ±3.4 ... 5
- Lowered minimum V_{IC}(±15Vcc) From: ±13.4V To: ±13.2V ... 5
- Deleted IMD (Intermodulation Distortion), ±12Vcc data, Dynamic Range (replaced with SNR, in 1V/V gain) ... 5
- Changed the THD=N UNIT From: % To: dB ... 5
- Changed the SNR to show the latest data from newer QFN based EVM. ... 5

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted) (1)

	MIN	MAX	UNIT
Supply voltage, xV_{CC+} to xV_{CC-} Where x=L or R channel	9	33	V
Input voltage, V_I (2)		± V_{CC}	
Differential input voltage, V_{ID}		6	V
Minimum load impedance		8	Ω
Continuous total power dissipation	See *Thermal Information*		
Operating free–air temperature range, T_A	–40	85	°C
Operating junction temperature range, T_J (3)	–40	150	°C
Storage Temperature, T_{stg}	–40	125	°C

(1) Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute–maximum–rated conditions for extended periods may affect device reliability.
(2) When the TPA6120A2 is powered down, the input source voltage must be kept below 600mV peak.
(3) The TPA6120A2 incorporates an exposed PowerPAD on the underside of the chip. This acts as a heatsink and must be connected to a thermally dissipating plane for proper power dissipation. Failure to do so may result in exceeding the maximum junction temperature that could permanently damage the device. See TI Technical Brief SLMA002 for more information about utilizing the PowerPAD thermally enhanced package.

7.2 ESD Ratings

				VALUE	UNIT
$V_{(ESD)}$	Electrostatic Discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 (1)	For Pins: LVCC+, RVCC+, LVCC-, RVCC	±500	V
		Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all other pins	For all pins except: LVCC+, RVCC+, LVCC-, RVCC	±2000	
		Charged device model (CDM), per JEDEC specification JESD22-C101		±1500	

(1) Level listed above is the passing level per ANSI, ESDA, and JEDEC JS-001. JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

		MIN	NOM	MAX	UNIT
Supply voltage, V_{CC+} and V_{CC-}	Split Supply	±5		±15	V
	Single Supply	10		30	
Load impedance	V_{CC} = ±5V or ±15V	16			Ω
Operating free–air temperature, T_A		–40		85	°C

7.4 Thermal Information

THERMAL METRIC (1)		TPA6120A2 DWP [HSOP] 20 PINS	TPA6120A2 RGY [VQFN] 14 PINS	UNIT
$R_{\theta JA}$	Junction-to-ambient thermal resistance	44.5	49.4	°C/W
$R_{\theta JCtop}$	Junction-to-case (top) thermal resistance	55.2	62.0	
$R_{\theta JB}$	Junction-to-board thermal resistance	36.1	25.4	
ψ_{JT}	Junction-to-top characterization parameter	23.1	1.6	
ψ_{JB}	Junction-to-board characterization parameter	36.2	25.5	
$R_{\theta JCbot}$	Junction-to-case (bottom) thermal resistance	7.6	6.2	

(1) For more information about traditional and new thermal metrics, see the *IC Package Thermal Metrics* application report, SPRA953.

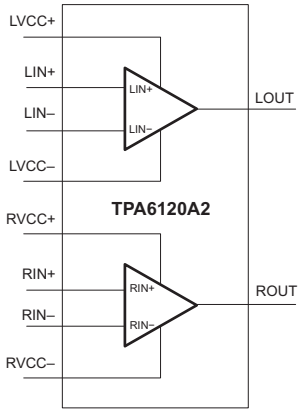
Figure 12. Test Circuit

9 Detailed Description

9.1 Overview

The TPA6120A2 is a current-feedback amplifier with differential inputs and single-ended outputs.

9.2 Functional Block Diagram



9.3 Feature Description

9.3.1 Current-Feedback Amplifier

Current feedback results in low voltage noise, low distortion, high open-loop gain throughout a large frequency range, and can be used in a similar fashion as voltage-feedback amplifiers. The low distortion of the TPA6120A2 results in a signal-to-noise ratio of 128 dB.

9.3.2 Independent Power Supplies

Because the power supplies for the two amplifiers are available separately, one amplifier can be turned off to conserve power.

See *Power Supply Recommendations*.

Copyright © 2004–2015, Texas Instruments Incorporated

9.4 Device Functional Modes

This device operates as a wide-bandwidth, current-feedback amplifier.

10 Applications and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

10.1 Application Information

In many applications, the audio source is digital, and must go through a digital-to-analog converter (DAC) so that traditional analog amplifiers can drive the speakers or headphones.

10.2 Typical Application

10.2.1 High Voltage, High Fidelity DAC + Headphone Amplifier Solution

Figure 13 shows a complete circuit schematic for such a system. The digital audio is fed into a high performance DAC. The PCM1792, a Burr-Brown product from TI, is a 24-bit, stereo DAC.

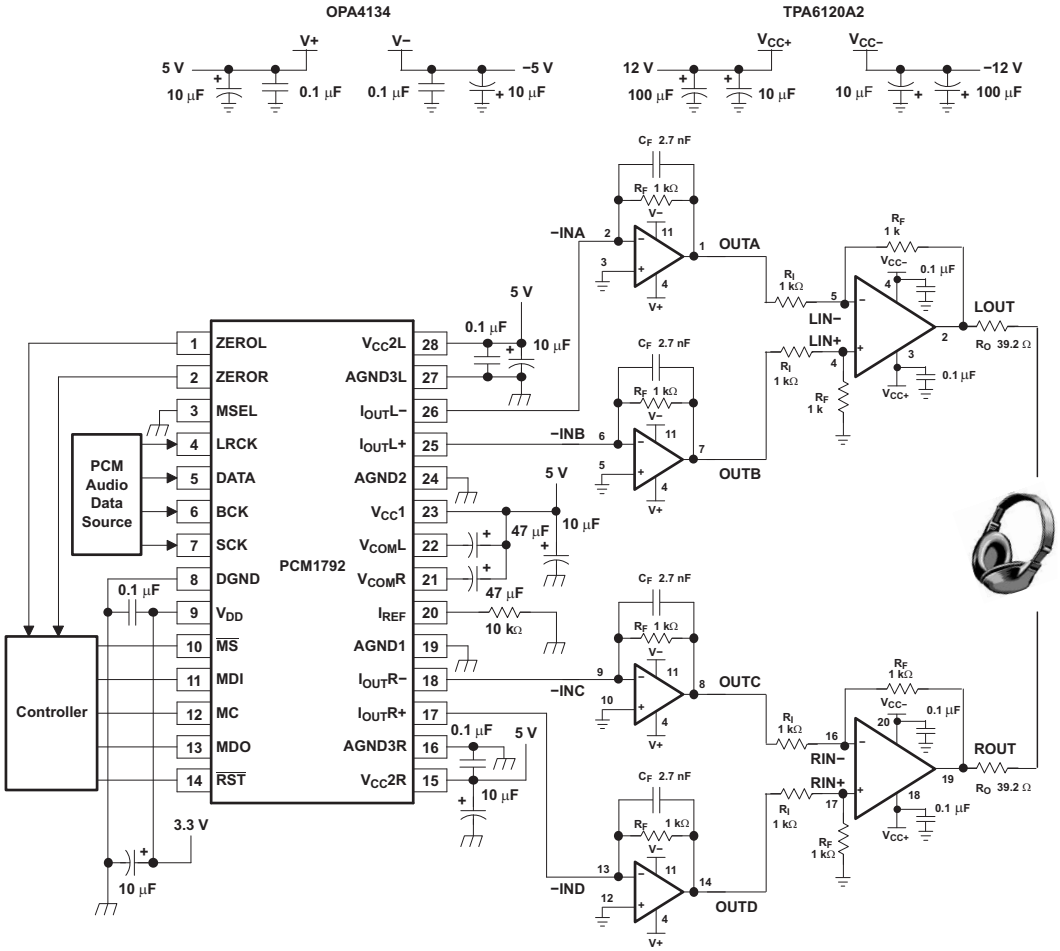


Figure 13. Typical Application Circuit

Typical Application (continued)

10.2.1.1 Design Requirements

- ±12V Operation from bipolar power supply
- Differential voltage source
- Be transparent to the user

10.2.1.2 Detailed Design Procedure

The output of the PCM1792 is current, not voltage, so the OPA4134 is used to convert the current input to a voltage output. The OPA4134 (SBOS058), is a low-noise, high-speed, high-performance operational amplifier. C_F and R_F are used to set the cutoff frequency of the filter. The RC combination in Figure 13 has a cutoff frequency of 59 kHz. All four amplifiers of the OPA4134 are used so the TPA6120A2 can be driven differentially.

The output of the OPA4134 goes into the TPA6120A2. The TPA6120A2 is configured for use with differential inputs, stereo use, and a gain of 2V/V. Note that the 0.1µF capacitors are placed at every supply pin of the TPA6120A2, as well as the 39.2Ω series output resistor.

Each output goes to one channel of a pair of stereo headphones, where the listener enjoys crisp, clean, virtually noise free music with a dynamic range greater than the human ear is capable of detecting.

10.2.1.2.1 Resistor Values

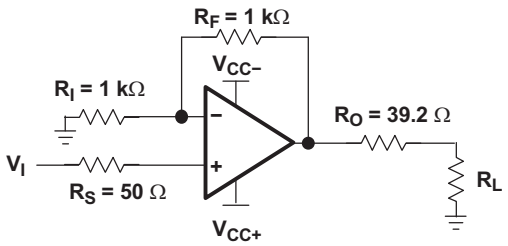

Figure 14. Single-Ended Input With A Noninverting Gain Of 2V/V

In the most basic configuration (see Figure 14), four resistors must be considered, not including the load impedance. The feedback and input resistors, R_F and R_I, respectively, determine the closed-loop gain of the amplifier. R_O is a series output resistor designed to protect the amplifier from any capacitance on the output path, including board and load capacitance. R_S is a series input resistor.

The series output resistor should be between 10Ω and 100Ω. The output series resistance eases the work of the output power stage by increasing the load when low impedance headphones are connected, as well as isolating any capacitance on the following traces and headphone cable.

Because the TPA6120A2 is a current-feedback amplifier, take care when choosing the feedback resistor. TI recommends a lower level of 800Ω for the feedback resistance. No capacitors should be used in the feedback path, as they will form a short circuit at high frequencies.

The value of the feedback resistor should be chosen by using Figure 17 as a guideline. The gain can then be set by adjusting the input resistor. The smaller the feedback resistor, the less noise is introduced into the system. However, smaller values move the dominant pole to higher and higher frequencies, making the device more susceptible to oscillations. Higher feedback resistor values add more noise to the system, but pull the dominant pole down to lower frequencies, making the device more stable. Higher impedance loads tend to make the device more unstable. One way to combat this problem is to increase the value of the feedback resistor. It is not recommended that the feedback resistor exceed a value of 10kΩ. The typical value for the feedback resistor for the TPA6120A2 is 1kΩ. In some cases, where a high-impedance load is used along with a relatively large gain and a capacitive load, it may be necessary to increase the value of the feedback resistor from 1kΩ to 2kΩ, thus adding more stability to the system. Another method to deal with oscillations is to increase the size of R_O.

CAUTION

Do not place a capacitor in the feedback path. Doing so can cause oscillations.

Copyright © 2004–2015, Texas Instruments Incorporated

Typical Application (continued)

Capacitance at the outputs can cause oscillations. Capacitance from some sources, such as layout, can be minimized. Other sources, such as those from the load (for example, the inherent capacitance in a pair of headphones), cannot be easily minimized. In this case, adjustments to R_O and/or R_F may be necessary.

The series output resistor should be kept at a minimum of 10Ω; small enough so that the effect on the load is minimal, but large enough to provide the protection necessary such that the output of the amplifier sees little capacitance. The value can be increased to provide further isolation, up to 100Ω. Care should be taken in selecting the thermal capacity of the output series resistor, as it will create a potential divider with the load and dissipate power.

The series resistor, R_S, should be used for two reasons:

1. It prevents the positive input pin from being exposed to capacitance from the line and source.
2. It prevents the source from seeing the input capacitance of the TPA6120A2.

The 50Ω resistor was chosen because it provides ample protection without interfering in any noticeable way with the signal. Not shown is another 50Ω resistor that can be placed on the source side of R_S to ground. In that capacity, it serves as an impedance match to any 50Ω source. See Figure 15.

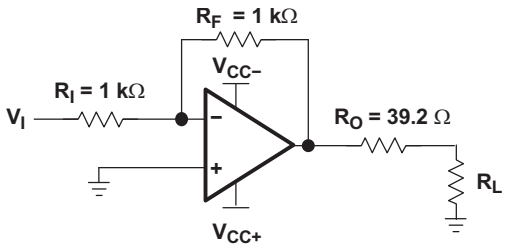

Figure 15. Single-Ended Input With A Noninverting Gain Of –1V/V

Figure 16 shows the TPA6120A2 connected with differential inputs. Differential inputs are useful because they take the greatest advantage of the high CMRR of the device. The two feedback resistor values must be kept the same, as do the input resistor values.

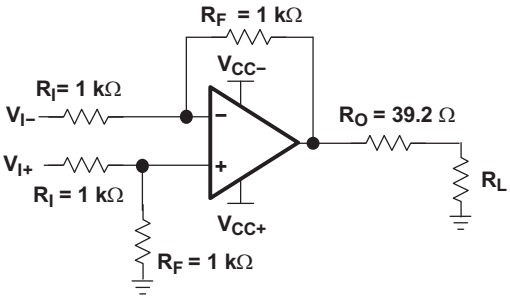

Figure 16. Differential Input With A Noninverting Gain Of 2V/V

Special note regarding mono operation:

- If both amplifiers are powered on, but only one channel is to be used, the unused amplifier MUST have a feedback resistor from the output to the negative input. Additionally, the positive input should be grounded as close to the pin as possible. Terminate the output as close to the output pin as possible with a 25Ω load to ground.
- These measures should be followed to prevent the unused amplifier from oscillating. If it oscillates, and the power pins of both amplifiers are tied together, the performance of the amplifier could be seriously degraded.

Copyright © 2004–2015, Texas Instruments Incorporated

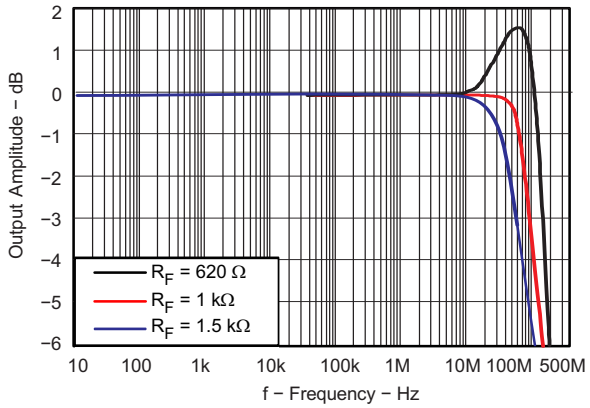
Typical Application (continued)

10.2.1.2.2 Checking For Oscillations And Instability

Checking the stability of the amplifier setup is recommended. High frequency oscillations in the megahertz region can cause undesirable effects in the audio band.

Sometimes, the oscillations can be quite clear. An unexpectedly large draw from the power supply may be an indication of oscillations. These oscillations can be seen with an oscilloscope. However, if the oscillations are not obvious, or there is a chance that the system is stable but close to the edge, placing a scope probe with 10pF of capacitance can make the oscillations worse, or actually cause them to start.

A network analyzer can be used to determine the inherent stability of a system. An output versus frequency curve generated by a network analyzer can be a good indicator of stability. At high frequencies, the curve shows whether a system is oscillating, close to oscillation, or stable. In Figure 17 the system is stable because the high frequency rolloff is smooth and has no peaking. Increasing R_F decreases the frequency at which this rolloff occurs (see the Resistor Values section). Another scenario shows some peaking at high frequency. If the peaking is 2dB, the amplifier is stable as there is still 45 degrees of phase margin. As the peaking increases, the phase margin shrinks, causing the amplifier and the system to approach instability. The same system that normally has a 2dB peak has an increased peak when a capacitor is added to the output, indicating that the system is either on the verge of oscillation or is oscillating; corrective action is required.



V_{CC} = ±5V Gain = 1V/V R_L = 25Ω
V_{IN} = 200mV

Figure 17. High Frequency Peaking for Oscillation and Instability

Copyright © 2004–2015, Texas Instruments Incorporated

Typical Application (continued)

10.2.1.2.3 Thermal Considerations

There is no one to one relationship between output power and heat dissipation, so the following equations must be used:

$$\text{Efficiency of an amplifier} = \frac{P_L}{P_{SUP}} \tag{1}$$

Where

$$P_L = \frac{V_{LRMS}^2}{R_L}, \text{ and } V_{LRMS} = \frac{V_P}{\sqrt{2}}, \text{ therefore, } P_L = \frac{V_P^2}{2R_L} \text{ per channel} \tag{2}$$

$$P_{SUP} = V_{CC}\, I_{CCavg} + V_{CC}\, I_{CC(q)} \tag{3}$$

$$I_{CCavg} = \frac{1}{\pi}\int_0^{\frac{\pi}{2}} \frac{V_P}{R_L} \sin(t)\, dt = -\frac{V_P}{\pi R_L}[\cos(t)]_0^{\frac{\pi}{2}} = \frac{V_P}{\pi R_L} \tag{4}$$

Where

$$V_P = \sqrt{2\, P_L\, R_L} \tag{5}$$

Therefore,

$$P_{SUP} = \frac{V_{CC}\, V_P}{\pi R_L} + V_{CC}\, I_{CC(q)} \tag{6}$$

P_L = Power delivered to load (per channel)
P_{SUP} = Power drawn from power supply
V_{LRMS} = RMS voltage on the load
R_L = Load resistance
V_P = Peak voltage on the load
I_{CC}avg = Average current drawn from the power supply
$I_{CC}(q)$ = Quiescent current (per channel)
V_{CC} = Power supply voltage (total supply voltage = 30 V if running on a ±15-V power supply
η = Efficiency of a SE amplifier

For stereo operation, the efficiency does not change because both P_L and P_{SUP} are doubled, affecting the amount of power dissipated by the package in the form of heat.

A simple formula for calculating the power dissipated, P_{DISS}, is shown in Equation 7:

$$P_{DISS} = (1 - \eta)\, P_{SUP} \tag{7}$$

In stereo operation, P_{SUP} is twice the quantity that is present in mono operation.

The maximum ambient temperature, T_A, depends on the heat-sinking ability of the system. $R_{\theta JA}$ for a 20-pin DWP, whose thermal pad is properly soldered down, is shown in *Thermal Information*. Also see Figure 18.

$$T_A\ \text{Max} = T_J\ \text{Max} - \theta_{JA}\ P_{DISS} \tag{8}$$

Copyright © 2004–2015, Texas Instruments Incorporated

10.2.1.3 Application Performance Plots

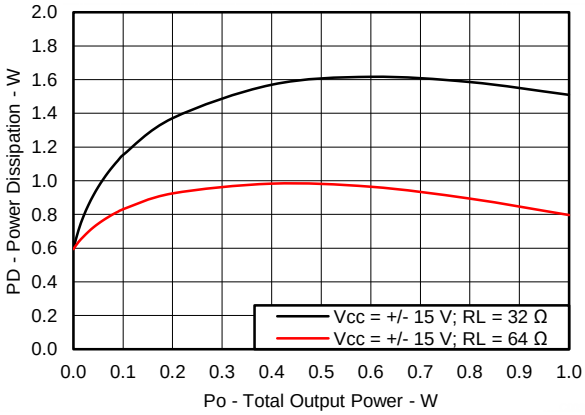


Figure 18. Power Dissipation versus Output Power

10.2.2 High Fidelity Smartphone Application

A new trend in portable applications are termed "Hifi Smartphones". In these systems, a standard portable audio codec continues to be used for telephony, while a separate, higher performance DAC and Headphone Amplifier is used for music playback.

Figure 19 shows a complete circuit schematic for such a system. The digital audio is fed into a high performance DAC. The PCM5242, a Burr-Brown product from TI, is a 32-bit, stereo DAC.

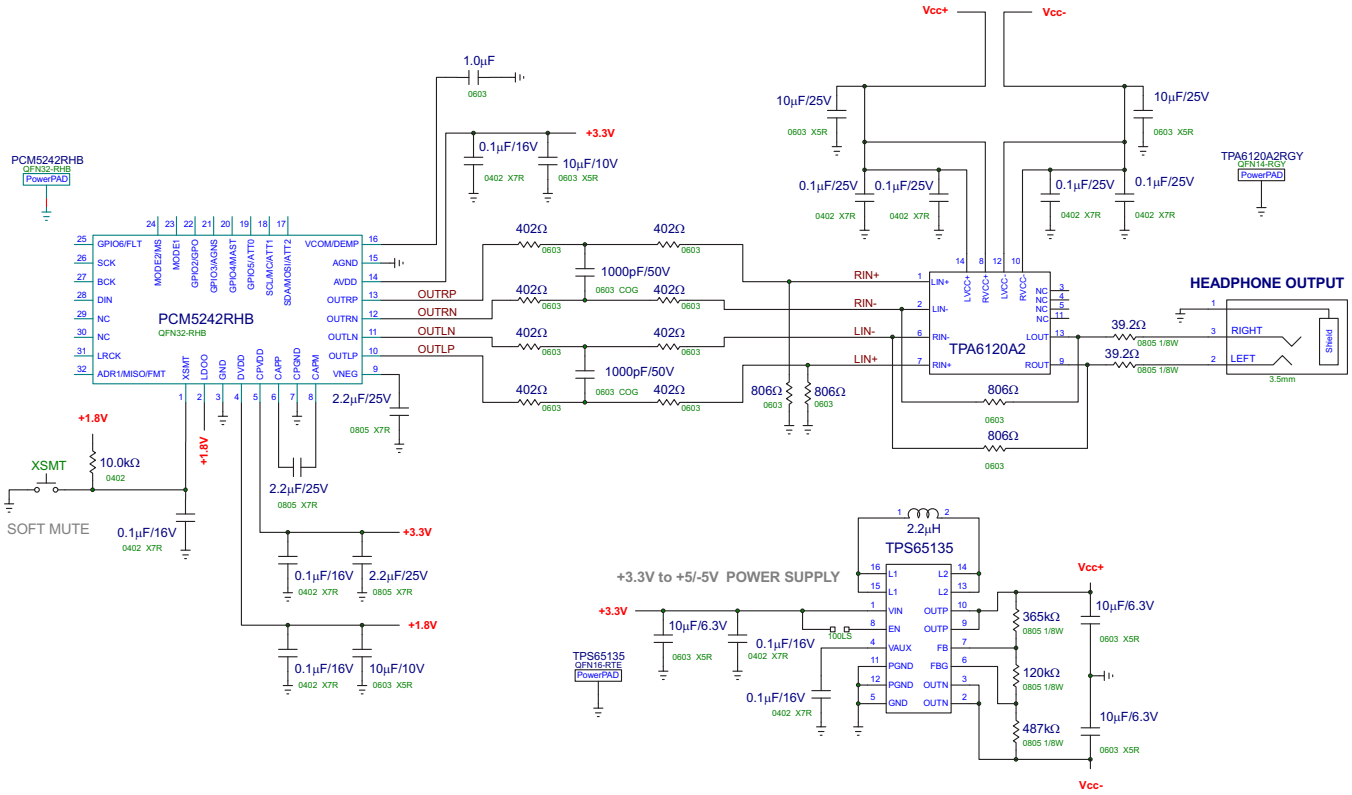

Figure 19. Typical Application Circuit

Copyright © 2004–2015, Texas Instruments Incorporated

10.2.2.1 Design Requirements

- ±5V Operation from an over system power supply of 3.3V
- Stereo differential inputs (DAC is differential)
- Be transparent to the user. (DAC SNR and THD+N performance all the way to the headphone)

10.2.2.2 Detailed Design Procedure

For optimal performance, the TPA6120A2 is configured for use with differential inputs, stereo use, and a gain of 1V/V.

The TPA6120A2 requires a bipolar power supply to drive a ground centered output. The application employs a TPS65135 DC-DC converter that generates ±5V from a single 3.3V supply.

The PCM5242 DAC is configured for a 1VRMS output so that clipping is avoided should the 3.3V power supply sag. The PCM5242 offers a ground centered output, so that no DC blocking capacitors are required between it and the TPA6120A2.

Resistor values around the TPA6120A2 of 806Ω and a 39.2Ω were found to offer the optimal conditions of SNR and THD. Starting with 1KΩ resistors for input and feedback, and 10Ω output resistance, the feedback resistance was lowered to increase the amount of current in the feedback network. The output resistance was increased to ease the load on the headphone amplifier when low impedance headphones are connected. Both of these additions contribute to the excellent SNR and THD of the TPA6120A2 in such a low voltage application.

Note that the 0.1-uF X7R capacitors are placed at every supply pin of the TPA6120A2.

Using such a solution makes the TPA6120A2 transparent in the circuit, even into a low impedance 32Ohm load.

The remaining steps are the same as those described in *Resistor Values*.

10.2.2.3 Application Performance Plots

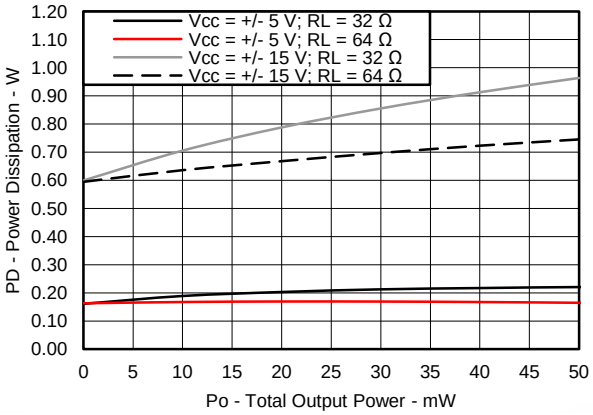

Figure 20. Power Dissipation versus Power Output - 50mW Scale

In this particular application, the TPA6120A2's performance is transparent and the performance of the system is dictated by the PCM5242 DAC.

Copyright © 2004–2015, Texas Instruments Incorporated

11 Power Supply Recommendations

11.1 Independent Power Supplies

The TPA6120A2 consists of two independent high-fidelity amplifiers. Each amplifier has its own voltage supply, allowing the user to leave one of the amplifiers off, saving power, reducing the generated heat, and reducing crosstalk.

Although the power supplies are independent, there are some limitations. When both amplifiers are used, the same voltage must be applied to each amplifier. For example, if the left channel amplifier is connected to a ±12-V supply, the right channel amplifier must also be connected to a ±12-V supply. If the device is connected to a different supply voltage, it may not operate properly and consistently.

When the use of only one amplifier is preferred, it must be the left amplifier. The voltage supply to the left amplifier is also responsible for internal start-up and bias circuitry of the device. Regardless of whether one or both amplifiers are used, the V_{CC-} pins of both amplifiers must always be at the same potential.

To power down the right channel amplifier, disconnect the V_{CC+} pin from the power source.

The two independent power supplies can be tied together on the board to receive their power from the same source.

11.2 Power Supply Decoupling

As with any design, proper power supply decoupling is essential. Decoupling prevents noise from entering the device via the power traces and provides the extra power the device can sometimes require in a rapid fashion, preventing the device from being momentarily current-starved. Both of these functions serve to reduce distortion, leaving a clean, uninterrupted signal at the output.

Bulk decoupling capacitors should be used where the main power is brought to the board. Smaller capacitors should be placed as close as possible to the actual power pins of the device. Because the TPA6120A2 has four power pins, use four surface mount capacitors. Both types of capacitors should be low ESR.

12 Layout

12.1 Layout Guidelines

Proper board layout is crucial to getting the maximum performance out of the TPA6120A2.

A ground plane should be used on the board to provide a low inductive ground connection. Having a ground plane underneath traces adds capacitance, so care must be taken when laying out the ground plane on the underside of the board (assuming a 2-layer board). The ground plane is necessary on the bottom for thermal reasons.

Stray capacitance can still make its way onto the sensitive outputs and inputs. Place components as close as possible to the pins and reduce trace lengths. See Figure 21 and Figure 22. Place the feedback resistor and the series output resistor extremely close to the pins. The input resistor should also be placed close to the pin. If the amplifier is to be driven in a noninverting configuration, ground the input close to the device so the current has a short, straight path to the PowerPAD (gnd).

12.2 Layout Example

This is part of a 4-layer board, where ground, V+, V- are on the bottom and two middle traces, respectively. Key items to note in this layout:

1. R4 and R3 are the output resistors in the schematic. They are sized as 0603 surface mount resistors instead of 0402 for their thermal capacity, as they will be dissipating heat, depending on the output power.
2. Traces are kept as short as possible to avoid any capacitance or oscillation issues.
3. In systems that may be using the DWP package with through hole resistors, it's strongly suggested that the input and output pins and components do not have a ground plane directly beneath them, to avoid stray capacitance.

13 Device and Documentation Support

13.1 Documentation Support

13.1.1 Related Documentation

Headphone Amplifier Parametric Table

SoundPlus™ High Performance Audio Operational Amplifiers, SBOS058

13.2 Trademarks

All trademarks are the property of their respective owners.

13.3 Electrostatic Discharge Caution

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

13.4 Glossary

SLYZ022 — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

14 Mechanical, Packaging, and Orderable Information

The following pages include mechanical packaging and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

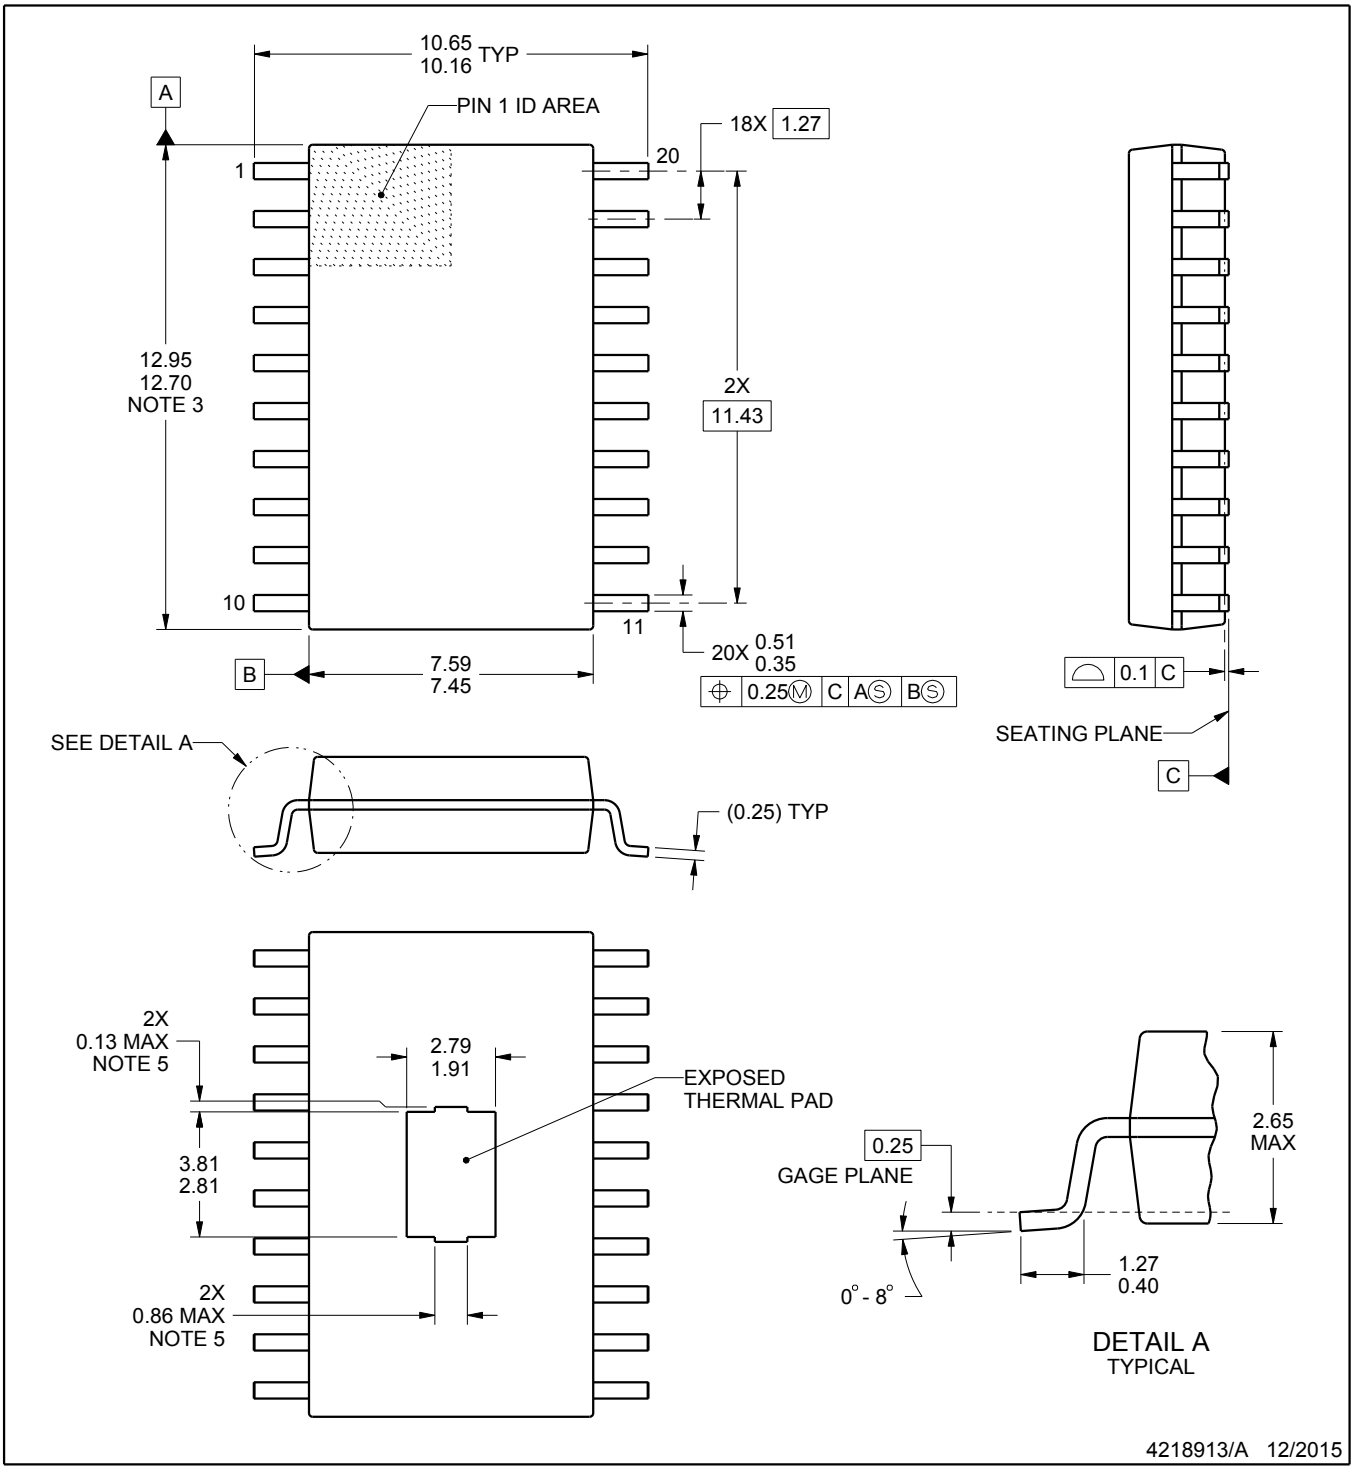
PACKAGE OUTLINE

DWP0020B

PowerPAD™ SOIC - 2.65 mm max height

PLASTIC SMALL OUTLINE



PowerPAD is a trademark of Texas Instruments.

NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm per side.
4. Features may not present.

NOTES: (continued)

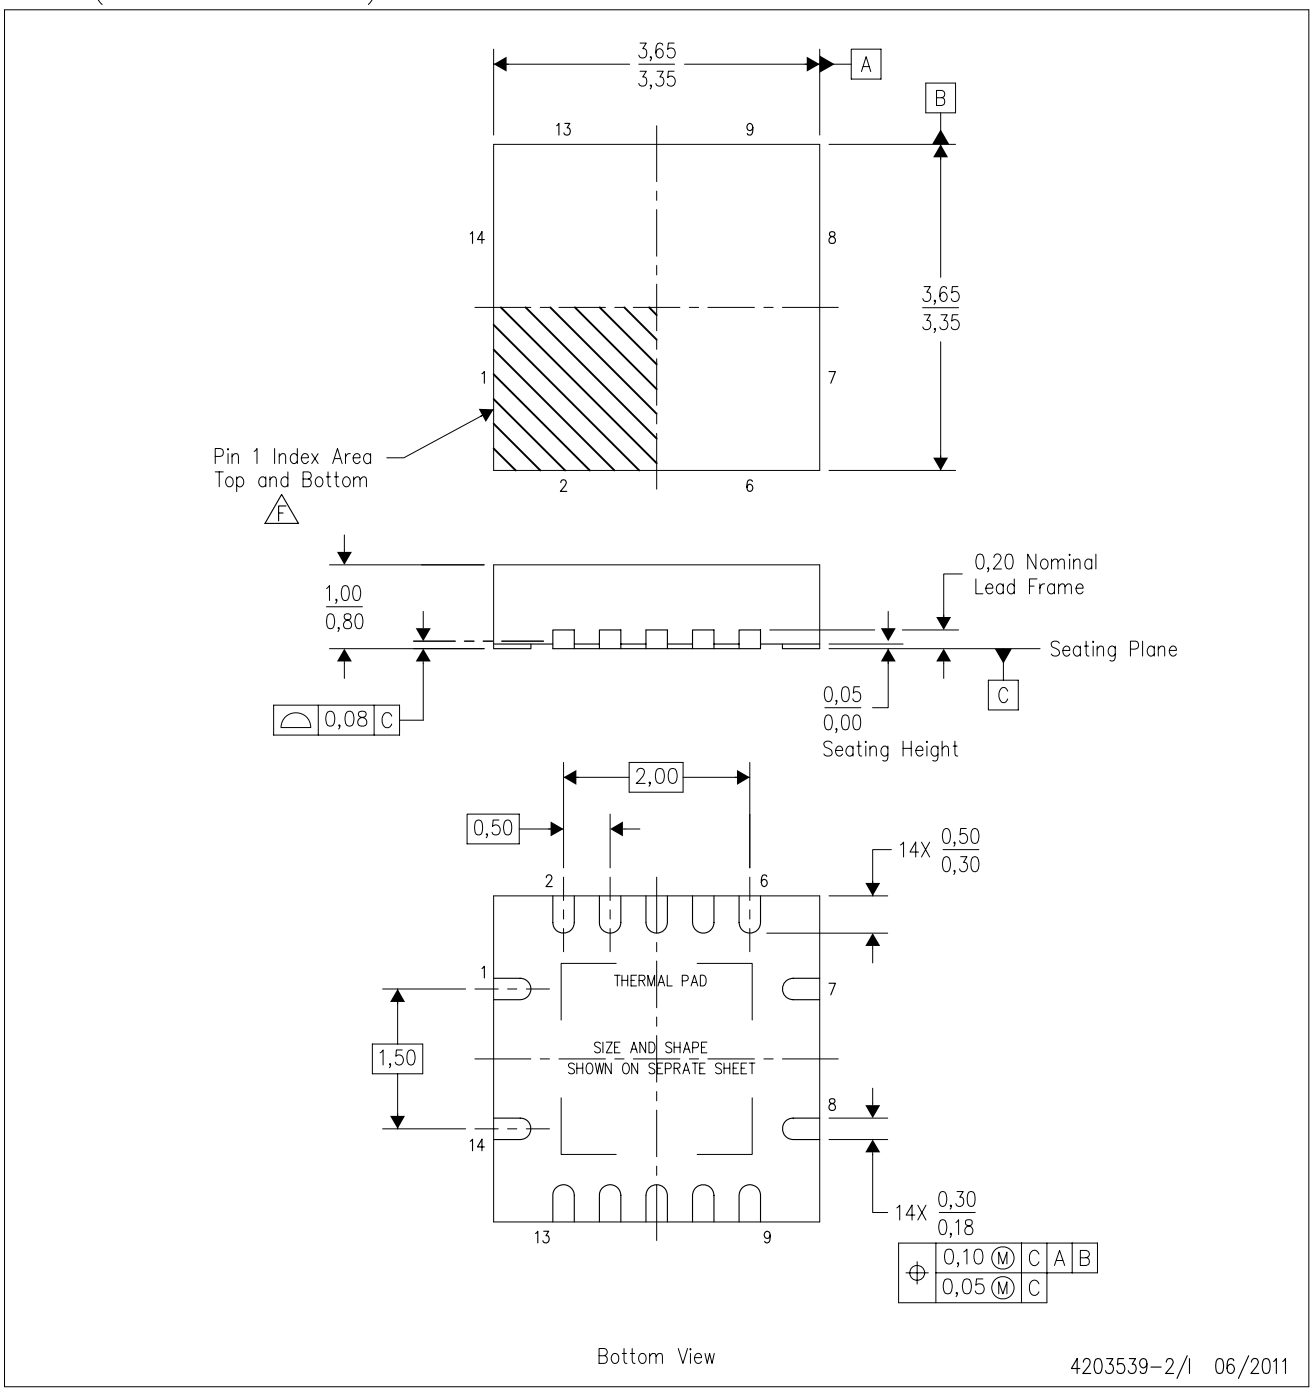
9. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
10. Board assembly site may have different recommendations for stencil design.

RGY (S–PVQFN–N14) PLASTIC QUAD FLATPACK NO–LEAD



NOTES:
A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M–1994.
B. This drawing is subject to change without notice.
C. QFN (Quad Flatpack No–Lead) package configuration.
D. The package thermal pad must be soldered to the board for thermal and mechanical performance.
E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
F. Pin 1 identifiers are located on both top and bottom of the package and within the zone indicated. The Pin 1 identifiers are either a molded, marked, or metal feature.
G. Package complies to JEDEC MO–241 variation BA.

RGY (S–PVQFN–N14) PLASTIC QUAD FLATPACK NO–LEAD

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No–Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

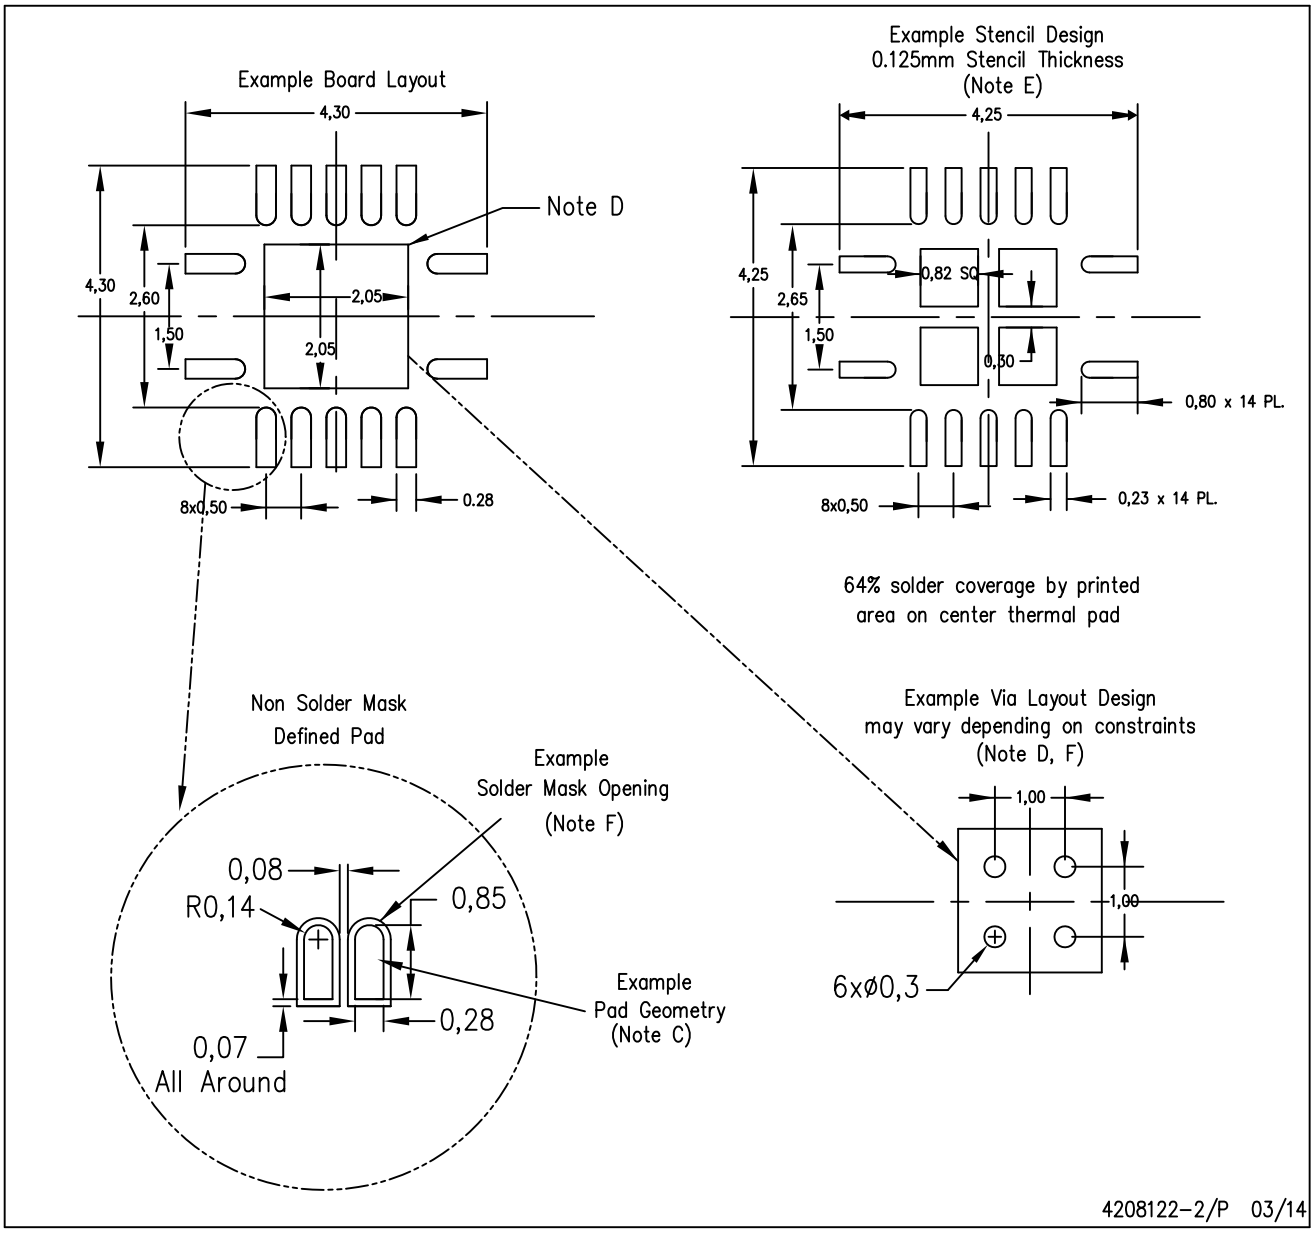
NOTE: All linear dimensions are in millimeters

RGY (S–PVQFN–N14) PLASTIC QUAD FLATPACK NO–LEAD



NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Publication IPC–7351 is recommended for alternate designs.
D. This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat–Pack QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <http: //www.ti.com>.
E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
F. Customers should contact their board fabrication site for minimum solder mask web tolerances between signal pads.

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
