

TPS54824 4.5V 至 17V 输入、电流模式、8A 同步 SWIFT™ 降压转换器

1 特性

- 小型 3.5mm x 3.5mm HotRod™ 四方扁平无引线 (QFN) 封装
- 集成的 14.1mΩ 和 6.1mΩ MOSFET
- 峰值电流模式控制，提供快速瞬态响应
- 200kHz 至 1.6MHz 的固定开关频率
- 与外部时钟同步
- 0.6V 电压基准，在广泛的温度范围内提供 $\pm 0.85\%$ 的精度
- 输出电压范围：0.6V 至 12V
- 断续电流限制
- 安全启动至预偏置输出电压
- 可调软启动和电源排序
- 可调节输入欠压锁定
- 3μA 关断电流
- 针对欠压及过压的电源良好输出监控
- 输出过压保护
- 非锁存热关断保护
- 运行结温范围：-40°C 至 150°C
- 由 WEBENCH® 设计中心提供支持

2 应用

- 电信和无线基础设施
- 工业自动化测试设备
- 企业交换和存储 应用
- 高密度分布式电源系统

3 说明

TPS54824 是具有完整功能的 17V、8A 同步降压转换器，采用了 3.5mm x 3.5mm HotRod™ QFN 封装。

该器件专门进行了优化，具有高效率并集成了高侧和低侧 MOSFET，适用于小型解决方案。它还通过使用峰值电流模式控制（可减少组件数量）并选择高开关频率（缩小电感器尺寸）进一步节省了空间。

峰值电流模式控制简化了环路补偿并可提供快速瞬态响应。在器件过载的情况下，针对高侧和低侧拉电流限制的逐周期峰值电流限制功能可保护器件。断续模式可在短路或者过载故障持续存在的情况下限制 MOSFET 功率损耗。

电源正常监控电路会对稳压器输出进行监控。PGOOD 引脚是一个开漏输出，会在输出电压调节过程中进入高阻抗。除非出现故障，否则内部抗尖峰脉冲时间会阻止拉低 PGOOD 引脚。

专用 EN 引脚可以用于控制稳压器开/关，并且调整输入欠压锁定。输出电压启动斜坡由 SS/TRK 引脚控制，该引脚既支持独立电源运行，又支持跟踪模式。

5 Pin Configuration and Functions

**RNV Package
18-Pin VQFN-HR**

Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
BOOT	1	I	Floating supply voltage for high-side MOSFET gate drive circuit. Connect a 0.1- μ F ceramic capacitor between BOOT and SW pins.
VIN	2, 11	I	Input voltage supply pin. Power for the internal circuit and the connection to drain of high-side MOSFET. Connect both pins to the input power source with a low impedance connection. Connect both pins and their neighboring PGND pins.
PGND	3, 4, 5, 8, 9, 10	–	Ground return for low-side power MOSFET and its drivers.
SW	6, 7	O	Switching node. Connected to the source of the high-side MOSFET and drain of the low-side MOSFET.
AGND	12	–	Ground of internal analog circuitry. AGND must be connected to the PGND plane.
RT/CLK	13	I	Switching frequency setting pin. In RT mode, an external timing resistor adjusts the switching frequency. In CLK mode, the device synchronizes to an external clock input to this pin.
FB	14	I	Converter feedback input. Connect to the output voltage with a resistor divider.
COMP	15	I	Error amplifier output and input to the PWM modulator. Connect loop compensation to this pin.
SS/TRK	16	I	Soft-start and tracking pin. Connecting an external capacitor sets the soft-start time. This pin can also be used for tracking and sequencing.
EN	17	I	Enable pin. Float or pull high to enable the device. Connect a resistor divider to this pin to implement adjustable under voltage lockout and hysteresis.
PGOOD	18	O	Open-drain power good indicator. It is asserted low if output voltage is outside if the PGOOD thresholds, VIN is low, EN is low, device is in thermal shutdown or device is in soft-start.

6 Specifications

6.1 Absolute Maximum Ratings

 over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
Voltage	V _{IN}	-0.3	19	V
	BOOT	-0.3	27	
	BOOT (10 ns transient)	-0.3	30	
	BOOT (vs SW)	-0.3	7	
	SW	-1	20	
	SW (10 ns transient)	-3	23	
EN, SS/TRK, PGOOD, RT/CLK, FB, COMP		-0.3	6.5	
Operating Junction Temperature Range, T _J		-40	150	°C
Storage Temperature Range, T _{STG}		-55	150	°C

- (1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

6.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins ⁽¹⁾	±2000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101, all pins ⁽²⁾	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
 (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

Parameter		MIN	NOM	MAX	UNIT
V _{IN}	Input voltage range	4.5		17	V
V _{OUT}	Output Voltage	0.6		12	V
I _{OUT}	Output current			8	A

7 Detailed Description

7.1 Overview

The TPS54824 is a 17-V, 8-A, synchronous step-down (buck) converter with two integrated n-channel MOSFETs. To improve performance during line and load transients the device implements a constant frequency, peak current mode control which also simplifies external frequency compensation. The wide switching frequency of 200 kHz to 1600 kHz allows for efficiency and size optimization when selecting the output filter components. The switching frequency is adjusted using a resistor to ground on the RT/CLK pin. The TPS54824 also has an internal phase lock loop (PLL) connected to the RT/CLK pin that can be used to synchronize the switching cycle to the falling edge of an external system clock.

The integrated MOSFETs allow for high efficiency power supply designs with continuous output currents up to 8 amperes. The MOSFETs have been sized to optimize efficiency for lower duty cycle applications. The device reduces the external component count by integrating a bootstrap recharge circuit. The bias voltage for the integrated high-side MOSFET is supplied by a capacitor between the BOOT and SW pins. The BOOT capacitor voltage is monitored by a BOOT to SW UVLO (BOOT-SW UVLO) circuit allowing SW pin to be pulled low to recharge the BOOT capacitor. The device can operate at 100% duty cycle as long as the BOOT capacitor voltage is higher than the preset BOOT-SW UVLO threshold which is typically 2.2 V.

The TPS54824 has been designed for safe monotonic startup into pre-biased loads. The default start up is when VIN is typically 4.1 V. The EN pin has an internal pull-up current source that can be used to adjust the input voltage under voltage lockout (UVLO) with two external resistors. In addition, the internal pull-up current of the EN pin allows the device to operate with the EN pin floating. The operating current for the TPS54824 is typically 580 μ A when not switching and under no load. When the device is disabled, the supply current is typically 3 μ A.

The SS/TRK (soft start/tracking) pin is used to minimize inrush currents or provide power supply sequencing during power up. A small value capacitor or resistor divider should be coupled to the pin for soft start or critical power supply sequencing requirements. The output voltage can be stepped down to as low as the 0.6 V voltage reference (V_{REF}). The device has a power good comparator (PGOOD) with hysteresis which monitors the output voltage through the FB pin. The PGOOD pin is an open drain MOSFET which is pulled low when the FB pin voltage is less than 89% or greater than 108% of the reference voltage V_{REF} and asserts high when the FB pin voltage is 91% to 106% of V_{REF} .

The device is protected from output overvoltage, overload and thermal fault conditions. The device minimizes excessive output overvoltage transients by taking advantage of the overvoltage circuit power good comparator. When the overvoltage comparator is activated, the high-side MOSFET is turned off and prevented from turning on until the FB pin voltage is lower than 106% of the V_{REF} . The device implements both high-side MOSFET over current protection and bidirectional low-side MOSFET over current protections which help control the inductor current and avoid current runaway. The device also shuts down if the junction temperature is higher than thermal shutdown trip point. The device is restarted under control of the soft start circuit automatically when the junction temperature drops 15°C typically below the thermal shutdown trip point.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Fixed Frequency PWM Control

The device uses an adjustable fixed frequency, peak current mode control. The output voltage is compared through external resistors on the FB pin to an internal voltage reference by an error amplifier which drives the COMP pin. An internal oscillator initiates the turn on of the high-side power switch. The error amplifier output is converted into a current reference which compares to the high-side power switch current. When the power switch current reaches current reference generated by the COMP voltage level the high-side power switch is turned off and the low-side power switch is turned on.

The device adds an internal slope compensation ramp to prevent subharmonic oscillations. The peak inductor current limit remains constant over the full duty cycle range.

7.3.2 Continuous Conduction Mode Operation (CCM)

As a synchronous buck converter, the device works in CCM (Continuous Conduction Mode) under all load conditions.

Feature Description (接下页)

7.3.3 VIN Pins and VIN UVLO

The VIN pin voltage supplies the internal control circuits of the device and provides the input voltage to the power converter system. The input voltage for VIN can range from 4.5 V to 17 V. The device implements internal UVLO circuitry on the VIN pin. The device is disabled when the VIN pin voltage falls below the internal VIN UVLO threshold. The internal VIN UVLO threshold has a hysteresis of 200 mV. A voltage divider connected to the EN pin can adjust the input voltage UVLO appropriately. See [Enable and Adjustable UVLO](#) for more details.

7.3.4 Voltage Reference and Adjusting the Output Voltage

The voltage reference system produces a precise $\pm 0.85\%$, 0.6 V voltage reference over temperature by scaling the output of a temperature stable band gap circuit. The output voltage is set with a resistor divider from the output (V_{OUT}) to the FB pin shown in [图 23](#). It is recommended to use 1% tolerance or better divider resistors. Start with a fixed value for the bottom resistor in the divider, typically 10 k Ω , then use [公式 1](#) to calculate the top resistor in the divider. To improve efficiency at light loads consider using larger value resistors. If the values are too high the regulator is more susceptible to noise and voltage errors from the FB input current are noticeable. The minimum output voltage and maximum output voltage can be limited by the minimum on time of the high side MOSFET and bootstrap voltage (BOOT-SW voltage) respectively.

Copyright © 2016, Texas Instruments Incorporated

图 23. FB Resistor Divider

$$R_{FBT} = R_{FBB} \times \left(\frac{V_{OUT}}{V_{REF}} - 1 \right) \quad (1)$$

7.3.5 Error Amplifier

The device uses a transconductance error amplifier. The error amplifier compares the FB pin voltage to the lower of the SS/TRK pin voltage or the internal 0.6-V voltage reference. The transconductance of the error amplifier is 1100 $\mu\text{A/V}$. The frequency compensation network is connected between the COMP pin and ground.

When operating at current limit the COMP pin voltage is clamped to a maximum level to improve response when the load current decreases. When FB is greater than the internal voltage reference or SS/TRK the COMP pin voltage is clamped to a minimum level and the devices enters a high-side skip mode.

7.3.6 Enable and Adjustable UVLO

The EN pin provides on/off control of the device. Once the EN pin voltage exceeds its threshold voltage, the device starts operation. If the EN pin voltage is pulled below the threshold voltage, the regulator stops switching and enters low operating current state. The EN pin has an internal pull-up current source, I_p , allowing the user to float the EN pin for enabling the device. If an application requires controlling the EN pin, an open drain or open collector output logic can be interfaced with the pin.

Feature Description (接下页)

An external resistor divider can be added from VIN to the EN pin for adjustable UVLO and hysteresis as shown in 图 24. The EN pin has a small pull-up current I_p which sets the default state of the pin to enable when no external components are connected. The pull-up current is also used to control the voltage hysteresis for the UVLO function since it increases by I_h once the EN pin crosses the enable threshold. The UVLO thresholds can be calculated using 公式 2 and 公式 3. When using the adjustable UVLO function, 500 mV or greater hysteresis is recommended.

Copyright © 2016, Texas Instruments Incorporated

图 24. Adjustable UVLO Using EN

$$R_{ENT} = \frac{V_{START} \times \left(\frac{V_{ENFALLING}}{V_{ENRISING}} \right) - V_{STOP}}{I_p \times \left(1 - \frac{V_{ENFALLING}}{V_{ENRISING}} \right) + I_h} \quad (2)$$

$$R_{ENB} = \frac{R_{ENT} \times V_{ENFALLING}}{V_{STOP} - V_{ENFALLING} + R_{ENT} \times (I_p + I_h)} \quad (3)$$

7.3.7 Soft Start and Tracking

The TPS54824 regulates to the SS/TRK pin while its voltage is lower than the internal reference to implement soft start. A capacitor on the SS/TRK pin to ground sets the soft start time. The SS/TRK pin has an internal pull-up current source of 5 μ A that charges the external soft start capacitor. 公式 4 calculates the required soft start capacitor value. The FB voltage will follow the SS/TRK pin voltage with a 25 mV offset up to 90% of the internal voltage reference. When the SS/TRK voltage is greater than 90% of the internal reference voltage the offset increases as the effective system reference transitions from the SS/TRK voltage to the internal voltage reference.

$$C_{SS} \text{ (nF)} = \frac{I_{SS} \text{ (\mu A)} \times t_{SS} \text{ (ms)}}{V_{REF} \text{ (V)}} = 8.3 \times t_{SS} \text{ (ms)} \quad (4)$$

If during normal operation, VIN goes below the UVLO, EN pin pulled below 1.15 V, or a thermal shutdown event occurs, the TPS54824 stops switching and the SS/TRK pin floats. When the VIN goes above UVLO, EN goes above 1.20 V, or a thermal shutdown is exited, the SS/TRK pin is discharged to near ground before reinitiating a powering up sequence.

Feature Description (接下页)

When the COMP pin voltage is clamped by the maximum COMP clamp in an overload condition the SS/TRK pin is discharged to near the FB voltage. When the overload condition is removed, the soft-start circuit controls the recovery from the fault output level to the nominal output regulation voltage. At the beginning of recovery a spike in the output voltage may occur while the COMP voltage transitions from the maximum clamp to the value determined by the loop.

7.3.8 Safe Start-up into Pre-Biased Outputs

The device has been designed to prevent the low-side MOSFET from discharging a pre-biased output. During monotonic pre-biased startup, the low-side MOSFET is not allowed to sink current until the SS/TRK pin voltage is higher than the FB pin voltage and the high-side MOSFET begins to switch. The one exception is if the BOOT-SW voltage is below the UVLO threshold. While in BOOT-SW UVLO, the low-side MOSFET is allowed to turn on to charge the BOOT capacitor. The low-side MOSFET reverse current protection provides another layer of protection for the device after the high-side MOSFET begins to switch.

7.3.9 Power Good

The PGOOD pin is an open-drain output requiring an external pull-up resistor to output a high signal. Once the FB pin is between 91% and 106% of the internal voltage reference and SS/TRK is greater than 0.75 V, after a 272 cycle deglitch time the PGOOD pin is de-asserted and the pin floats. A pull-up resistor between the values of 10 k Ω and 100 k Ω to a voltage source that is 6.5 V or less is recommended. PGOOD is in a defined state once the VIN input voltage is greater than 1 V but with reduced current sinking capability.

When the FB is lower than 89% or greater than 108% of the nominal internal reference voltage, after a 16 cycle deglitch time the PGOOD pin is pulled low. PGOOD is immediately pulled low if VIN falls below its UVLO, EN pin is pulled low or the TPS54824 enters thermal shutdown.

Feature Description (接下页)

7.3.10 Sequencing (SS/TRK)

Many of the common power supply sequencing methods can be implemented using the SS/TRK, EN and PGOOD pins.

The sequential method is illustrated in 图 25 using two TPS54824 or similar devices. The power good of the first device is coupled to the EN pin of the second device which enables the second power supply once the primary supply reaches regulation.

图 26 shows the method implementing ratiometric sequencing by connecting the SS/TRK pins of two devices together. The regulator outputs ramp up and reach regulation at the same time. When calculating the soft-start time the current source must be doubled in 公式 4.

图 25. Sequential Start-Up Sequence

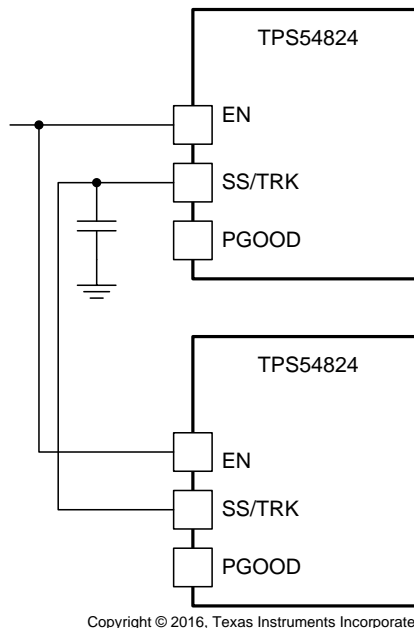

图 26. Ratiometric Start-Up Sequence

Feature Description (接下页)

Ratiometric and simultaneous power supply sequencing can be implemented by connecting the resistor network of R_{TRT} and R_{TRB} shown in 图 27 to the output of the power supply that needs to be tracked or another voltage reference source. Using 公式 6 and 公式 7, the tracking resistors can be calculated to initiate the V_{OUT2} slightly before, after or at the same time as V_{OUT1} . 公式 5 is the voltage difference between V_{OUT1} and V_{OUT2} .

To design a ratiometric start-up in which the V_{OUT2} voltage is slightly greater than the V_{OUT1} voltage when V_{OUT2} reaches regulation, use a negative number in 公式 6 and 公式 7 for ΔV . 公式 5 results in a positive number for applications where the V_{OUT2} is slightly lower than V_{OUT1} when V_{OUT2} regulation is achieved.

The ΔV variable is zero volts for simultaneous sequencing. To minimize the effect of the inherent SS/TRK to FB offset ($V_{ssoffset} = 25\text{ mV}$) in the soft-start circuit and the offset created by the pull-up current source ($I_{ss} = 5\text{ }\mu\text{A}$) and tracking resistors, the $V_{ssoffset}$ and I_{ss} are included as variables in the equations.

To ensure proper operation of the device, the calculated R_{TRT} value from 公式 6 must be greater than the value calculated in 公式 8.

$$\Delta V = V_{OUT1} - V_{OUT2} \quad (5)$$

$$R_{TRT} = \frac{V_{OUT2} + \Delta V}{V_{REF}} \times \frac{V_{ssoffset}}{I_{ss}} \quad (6)$$

$$R_{TRB} = \frac{V_{REF} \times R_{TRT}}{V_{OUT2} + \Delta V - V_{REF}} \quad (7)$$

$$R_{TRT} > 2800 \times V_{OUT1} - 180 \times \Delta V \quad (8)$$

Feature Description (接下页)

7.3.11 Adjustable Switching Frequency (RT Mode)

In RT mode, a resistor (RT resistor) is connected between the RT/CLK pin and AGND. The switching frequency of the device is adjustable from 200 kHz to 1600 kHz by placing a maximum of 250 kΩ and minimum of 30.1 kΩ respectively. To determine the RT resistance for a given switching frequency, use 公式 9. To reduce the solution size one would set the switching frequency as high as possible, but tradeoffs of the supply efficiency and minimum controllable on-time should be considered. 公式 10 can be used to calculate the switching frequency for a given RT resistance.

$$RT(k\Omega) = 58650 \times f_{SW} (kHz)^{-1.028} \quad (9)$$

$$f_{SW} (kHz) = 43660 \times RT(k\Omega)^{-0.973} \quad (10)$$

7.3.12 Synchronization (CLK Mode)

An internal Phase Locked Loop (PLL) has been implemented to allow synchronization from 200 kHz to 1600 kHz, and to easily switch from RT mode to CLK mode. To implement the synchronization feature, connect a square wave clock signal to the RT/CLK pin with a duty cycle from 20% to 80%. The clock signal amplitude must transition lower than 0.8 V and higher than 2 V. The start of the switching cycle is synchronized to the falling edge of the RT/CLK pin.

In applications where both RT mode and CLK mode are needed, the device can be configured as shown in 图 28. Before the external clock is present, the device works in RT mode and the switching frequency is set by RT resistor. When the external clock is present, the CLK mode overrides the RT mode. The first time the SYNC pin is pulled above the RT/CLK high threshold (2 V), the device switches from the RT mode to the CLK mode and the RT/CLK pin becomes high impedance as the PLL starts to lock onto the frequency of the external clock.

If the input clock goes away the internal clock frequency begins to drop and after 10 μs without a clock the device returns to RT mode. Output undershoot while the switching frequency drops can occur. Output overshoot can also occur when the switching frequency steps back up to the RT mode frequency. A high impedance tri-state buffer as shown in 图 30 is recommended for best performance during the transition from CLK mode to RT mode because it minimizes the loading on the RT/CLK pin allowing faster transition back to RT mode. 图 31 shows the typical performance for the transition from RT mode to CLK mode then back to RT mode. A series RC circuit as shown in 图 29 can also be used to interface the RT/CLK pin but the capacitive load slows down the transition back to RT mode. The series RC circuit is not recommended if the transition from CLK mode to RT mode is important.

7.3.13 Bootstrap Voltage and 100% Duty Cycle Operation (BOOT)

The device provides an integrated bootstrap voltage regulator. A small capacitor between the BOOT and SW pins provides the gate drive voltage for the high side MOSFET. The BOOT capacitor is refreshed when the low-side MOSFET is on. The recommended value of the BOOT capacitor is 0.1 μ F. A ceramic capacitor with an X7R or X5R grade dielectric with a voltage rating of 10 V or higher is recommended for stable performance over temperature and voltage.

When operating with a low voltage difference from input to output, the high side MOSFET of the device will operate at 100% duty cycle as long as the BOOT to SW pin voltage is greater than 2.2 V. The device will begin to transition to 100% duty cycle operation when the high-side MOSFET off-time is less than 100 ns typical. When the voltage from BOOT to SW drops below 2.2 V, the high-side MOSFET is turned off due to BOOT UVLO and the low side MOSFET pulls SW low to recharge the BOOT capacitor. When operating at 100% duty cycle the high-side MOSFET can remain on for many switching cycles before the MOSFET is turned off to refresh the capacitor because the gate drive current sourced by the BOOT capacitor is small. The effective switching frequency reduced and the effective maximum duty cycle of the switching regulator is near 100%. The output voltage of the converter during dropout is mainly influenced by the voltage drops across the power MOSFET, the inductor resistance, and the printed circuit board resistance.

7.3.14 Output Overvoltage Protection (OVP)

The TPS54824 incorporates an output overvoltage protection (OVP) circuit to minimize output voltage overshoot. The OVP feature minimizes the overshoot by comparing the FB pin voltage to the OVP threshold. The OVP threshold is the same as the 108% PGOOD threshold. If the FB pin voltage is greater than the OVP threshold the high-side MOSFET is turned off preventing current from flowing to the output and minimizing output overshoot. When the high-side MOSFET turns off, the low-side MOSFET turns on and the current in the inductor discharges. The output voltage can overshoot the OVP threshold as the current in the inductor discharges to 0 A. When the FB voltage drops lower than the 106% PGOOD threshold, the high-side MOSFET is allowed to turn on at the next clock cycle.

7.3.15 Overcurrent Protection

The device is protected from overcurrent conditions by cycle-by-cycle current limiting on both the high-side MOSFET and the low-side MOSFET. In an extended overcurrent condition the device will enter hiccup to reduce power dissipation.

Feature Description (接下页)

7.3.15.1 High-side MOSFET Overcurrent Protection

The device implements current mode control which uses the COMP pin voltage to control the turnoff of the high-side MOSFET and the turnon of the low-side MOSFET on a cycle-by-cycle basis. Each cycle the switch current and the current reference generated by the COMP pin voltage are compared, when the peak switch current intersects the current reference the high-side switch is turned off. The maximum peak switch current through the high-side MOSFET for overcurrent protection is done by limiting the current reference internally. If the peak current required to regulate the output is greater than the internal limit, the output voltage is pulled low and the error amplifier responds by driving the COMP pin high. The maximum COMP voltage is then clamped by an internal COMP clamp circuit. If the COMP voltage is clamped high for more than the hiccup wait time of 512 switching cycles, the device will shut down itself and restart after the hiccup time of 16384 cycles.

7.3.15.2 Low-side MOSFET Overcurrent Protection

While the low-side MOSFET is turned on the current through it is monitored. During normal operation the low-side MOSFET sources current to the load. At the end of every clock cycle, the low-side MOSFET sourcing current is compared to the internally set low-side sourcing current limit. If the low-side sourcing current is exceeded the high-side MOSFET is not turned on and the low-side MOSFET stays on for the next cycle. The high-side MOSFET is turned on again when the low-side current is below the low-side sourcing current limit at the start of a cycle. The low-side sourcing current limit prevents current runaway.

The low-side MOSFET may also sink current from the load. If the low-side sinking current limit is exceeded the low-side MOSFET is turned off immediately for the rest of that clock cycle. In this scenario both MOSFETs are off until the start of the next cycle. If the low-side MOSFET turns off due to sinking current limit protection, the low-side MOSFET can only turn on again after the high-side MOSFET turns on then off or if the device enters BOOT UVLO.

7.4 Device Functional Modes

The EN pin and a VIN UVLO is used to control turn on and turn off of the TPS54824. The device becomes active when $V_{(VIN)}$ exceeds the 4.1 V typical UVLO and when $V_{(EN)}$ exceeds 1.20 V typical. The EN pin has an internal current source to enable the output when the EN pin is left floating. If the EN pin is pulled low the device is put into a low quiescent current state.

8 Application and Implementation

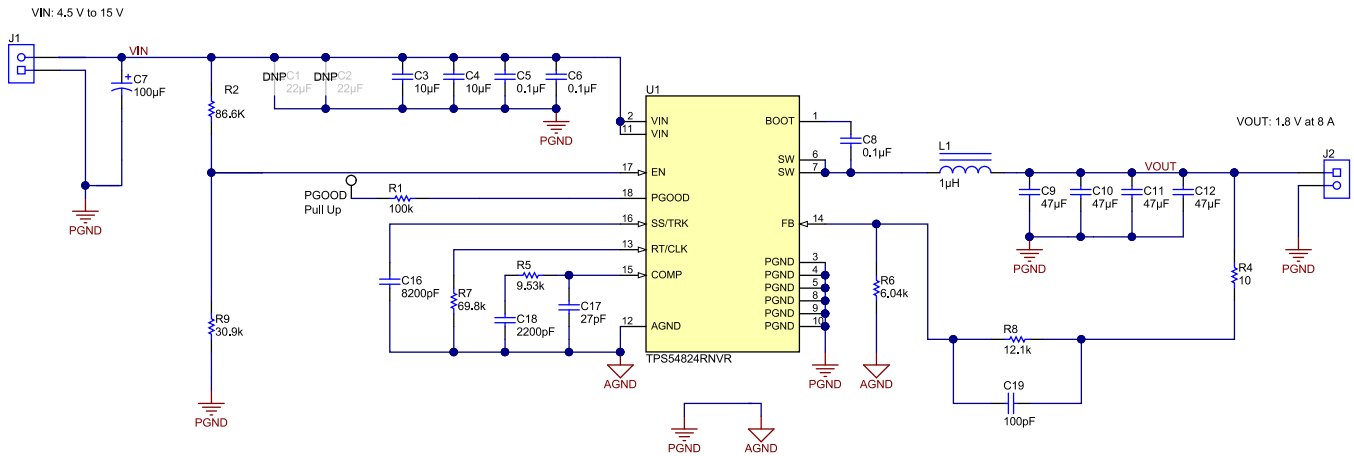

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The TPS54824 is a synchronous buck converter designed for 4.5 V to 17 V input and 8-A load. This procedure illustrates the design of a high-frequency switching regulator using ceramic output capacitors. Alternatively the WEBENCH[®] software can be used to generate a complete design. The WEBENCH[®] software uses an interactive design procedure and accesses a comprehensive database of components when generating a design. This section presents a simplified discussion of the design process.

8.2 Typical Application

图 32. TPS54824 4.5-V to 15-V Input, 1.8-V Output Converter Application Schematic

8.2.1 Design Requirements

For this design example, use the parameters shown in 表 1.

表 1. Design Parameters

PARAMETER	EXAMPLE VALUE
Input voltage range (V_{IN})	4.5 to 15 V, 12 V Nominal
Output voltage (V_{OUT})	1.8 V
Transient response	+/- 4%, +/- 72 mV
Output ripple voltage	0.5%, 9 mV
Output current rating (I_{OUT})	8 A
Operating frequency (f_{SW})	700 kHz

8.2.2 Detailed Design Procedure

8.2.2.1 Switching Frequency

The first step is to decide on a switching frequency for the converter. It is capable of running from 200 kHz to 1.6 MHz. Typically the highest switching frequency possible is desired because it will produce the smallest solution size. A high switching frequency allows for lower valued inductors and smaller output capacitors compared to a power supply that switches at a lower frequency. The main trade off made with selecting a higher switching frequency is extra switching power loss, which hurt the converter's efficiency.

The maximum switching frequency for a given application is limited by the minimum on-time of the converter and is estimated with 公式 11. Using a maximum minimum on-time of 150 ns for the TPS54824 and 15 V maximum input voltage for this application, the maximum switching frequency is 800 kHz. Considering the 10% tolerance of the switching frequency, a switching frequency of 700 kHz was selected. 公式 12 calculates R7 to be 69.7 kΩ. A standard 1% 69.8 kΩ value was chosen in the design.

$$f_{\text{SW}}(\text{max}) = \frac{1}{t_{\text{onmin}}} \times \frac{V_{\text{OUT}}}{V_{\text{IN}}(\text{max})} \quad (11)$$

$$RT(\text{k}\Omega) = 58650 \times f_{\text{SW}}(\text{kHz})^{-1.028} \quad (12)$$

8.2.2.2 Output Inductor Selection

To calculate the value of the output inductor, use 公式 13. K_{IND} is a ratio that represents the amount of inductor ripple current relative to the maximum output current. The inductor ripple current is filtered by the output capacitor. Therefore, choosing high inductor ripple currents impacts the selection of the output capacitor since the output capacitor must have a ripple current rating equal to or greater than the inductor ripple current. Additionally with current mode control the sensed inductor current ripple is used in the PWM modulator. Choosing small inductor ripple currents can degrade the transient response performance or introduce jitter in the duty cycle. The inductor ripple, K_{IND} is normally from 0.2 to 0.4 for the majority of applications giving a peak to peak ripple current range of 1.6 A to 3.2 A. For applications requiring operation near the minimum on-time, with on-times less than 200 ns, the target ripple must be 2.4 A or larger. For other applications the target ripple should be 0.8 A or larger.

For this design example, $K_{\text{IND}} = 0.3$ is used and the inductor value is calculated to be 0.94 μH. The next standard value 1 μH is selected. It is important that the RMS current and saturation current ratings of the inductor not be exceeded. The RMS and peak inductor current can be found from 公式 15 and 公式 16. For this design, the RMS inductor current is 8.0 A and the peak inductor current is 9.1 A. The chosen inductor is a Cyttec CMLE063T-1R0MS. It has a saturation current rating of 16.0 A (30% inductance loss) and a RMS current rating of 16.0 A (40 °C temperature rise). The DC series resistance is 5.6 mΩ typical.

The current flowing through the inductor is the inductor ripple current plus the output current. During power up, faults or transient load conditions, the inductor current can increase above the calculated peak inductor current level calculated in 公式 16. In transient conditions, the inductor current can increase up to the switch current limit of the device. For this reason, the most conservative approach is to specify the ratings of the inductor based on the switch current limit rather than the steady-state peak inductor current.

$$L1 = \frac{V_{\text{inmax}} - V_{\text{out}}}{I_{\text{o}} \times K_{\text{IND}}} \times \frac{V_{\text{out}}}{V_{\text{inmax}} \times f_{\text{sw}}} \quad (13)$$

$$I_{\text{ripple}} = \frac{V_{\text{inmax}} - V_{\text{out}}}{L1} \times \frac{V_{\text{out}}}{V_{\text{inmax}} \times f_{\text{sw}}} \quad (14)$$

$$I_{\text{Lrms}} = \sqrt{I_{\text{o}}^2 + \frac{1}{12} \times \left(\frac{V_{\text{o}} \times (V_{\text{inmax}} - V_{\text{o}})}{V_{\text{inmax}} \times L1 \times f_{\text{sw}}} \right)^2} \quad (15)$$

$$I_{Lpeak} = I_{out} + \frac{I_{ripple}}{2} \quad (16)$$

8.2.2.3 Output Capacitor

There are two primary considerations for selecting the value of the output capacitor. The output voltage ripple and how the regulator responds to a large change in load current. The output capacitance needs to be selected based on the more stringent of these two criteria.

The desired response to a large change in the load current is the first criteria and is typically the most stringent. The output capacitor supplies or absorbs charge until the regulator responds to the load step. The regulator does not respond immediately to a large, fast increase or decrease in load current. A regulator usually needs two or more clock cycles for the control loop to sense the change in output voltage then adjust the peak switch current in response to the change in load. As an estimation, the output capacitance must be large enough to supply the difference in current for 2 clock cycles to maintain the output voltage within the specified range. At higher switching frequencies the fastest response time is limited to about 2 μ s. 公式 17 shows the minimum output capacitance necessary, where ΔI_{OUT} is the change in output current, $t_{response}$ is the regulator's estimated response time and ΔV_{OUT} is the allowable change in the output voltage. The maximum of $2/f_{sw}$ or 2 μ s should be used for the response time in the output capacitance calculation. The response to a transient load also depends on the loop compensation and slew rate of the transient load. This calculation assumes the loop compensation is designed for the output filter with the equations later on in this procedure.

For this example, the transient load response is specified as a 4% change in V_{OUT} for a load step of 4 A. Therefore, ΔI_{OUT} is 4 A and ΔV_{OUT} is 72 mV. Using these numbers with a 2.9 μ s response time gives a target capacitance of 159 μ F. This value does not take the ESR of the output capacitor into account in the output voltage change. For ceramic capacitors, the effect of the ESR can be small enough to be ignored. Aluminum electrolytic and tantalum capacitors have higher ESR that must be considered for load step response.

公式 18 calculates the minimum output capacitance needed to meet the output voltage ripple specification. Where f_{sw} is the switching frequency, V_{ripple} is the maximum allowable output voltage ripple, and I_{ripple} is the inductor ripple current. In this case, the target maximum output voltage ripple is 9 mV. Under this requirement, 公式 18 yields 46 μ F.

$$C_o > t_{response} \times \frac{\Delta I_{out}}{\Delta V_{out}} \quad (17)$$

$$C_o > \frac{1}{8 \times f_{sw}} \times \frac{1}{\frac{V_{ripple}}{I_{ripple}}} \quad (18)$$

Where:

- ΔI_{OUT} is the change in output current
- ΔV_{OUT} is the allowable change in the output voltage
- f_{sw} is the regulators switching frequency

公式 19 calculates the maximum combined ESR the output capacitors can have to meet the output voltage ripple specification and this shows the ESR should be less than 4 m Ω . In this case ceramic capacitors will be used and the combined ESR of the ceramic capacitors in parallel is much less than 4 m Ω . Capacitors also have limits to the amount of ripple current they can handle without producing excess heat and failing. An output capacitor that can support the inductor ripple current must be specified. Capacitor datasheets specify the RMS (Root Mean Square) value of the maximum ripple current. 公式 20 can be used to calculate the RMS ripple current the output capacitor needs to support. For this application, 公式 20 yields 660 mA and the ceramic capacitors used in this design will have a ripple current rating much higher than this.

$$Resr < \frac{V_{ripple}}{I_{ripple}} \quad (19)$$

$$I_{\text{corms}} = \frac{V_{\text{out}} \times (V_{\text{inmax}} - V_{\text{out}})}{\sqrt{12} \times V_{\text{inmax}} \times L1 \times f_{\text{sw}}} \quad (20)$$

X5R and X7R ceramic dielectrics or similar should be selected for power regulator capacitors because they have a high capacitance to volume ratio and are fairly stable over temperature. The output capacitor must also be selected with the DC bias and AC voltage derating taken into account. The derated capacitance value of a ceramic capacitor due to DC voltage bias and AC RMS voltage is usually found on the manufacturer's website. For this application example, four 47 μF 6.3 V 1206 X5R ceramic capacitors each with 3 m Ω of ESR are used. The estimated capacitance after derating using the capacitor manufacturer's website is 29 μF each. With 4 parallel capacitors the total output capacitance is 116 μF and the ESR is 0.7 m Ω . The effective capacitance used is less than originally calculated above because testing the real circuit on the bench showed that less capacitance was required to achieve the desired response.

8.2.2.4 Input Capacitor

The TPS54824 requires input decoupling ceramic capacitors type X5R, X7R or similar from VIN to PGND placed as close as possible to the IC. At least 4.7 μF of effective capacitance is required and some applications may require a bulk capacitance. A 0.1 μF capacitor must be placed by both VIN pins 2 and 11 to provide high frequency bypass to reduce overshoot and ringing on VIN and SW. The additional bypass capacitance can be placed near either pin. The effective capacitance must include any DC voltage bias and AC voltage effects. The voltage rating of the input capacitor must be greater than the maximum input voltage. The capacitor must also have a ripple current rating greater than the maximum RMS input current of the TPS54824. The RMS input current can be calculated using [公式 21](#).

For this example design, a ceramic capacitor with at least a 25 V voltage rating is required to support the maximum input voltage. Two 10 μF 1206 X5R 35 V and two 0.1 μF 0603 X7R 25 V capacitors in parallel has been selected to be placed on both sides of the IC near both VIN pins to PGND pins. Based on the capacitor manufacturer's website, the total ceramic input capacitance derates to 5.6 μF at the nominal input voltage of 12 V. A 100 μF bulk capacitance is also used in this circuit to bypass long leads when connected a lab bench top power supply.

The input capacitance value determines the input ripple voltage of the regulator. The input voltage ripple can be calculated using [公式 22](#). The maximum input ripple occurs when operating nearest to 50% duty cycle. Using the nominal design example values of $I_{\text{outmax}} = 8 \text{ A}$, $C_{\text{in}} = 5.6 \mu\text{F}$, and $f_{\text{SW}} = 700 \text{ kHz}$, the input voltage ripple with the 12 V nominal input is 260 mV and the RMS input ripple current with the 4.5 V minimum input is 3.0 A.

$$I_{\text{cirms}} = I_{\text{out}} \times \sqrt{\frac{V_{\text{out}}}{V_{\text{inmin}}} \times \frac{(V_{\text{inmin}} - V_{\text{out}})}{V_{\text{inmin}}}} \quad (21)$$

$$\Delta V_{\text{in}} = \frac{I_{\text{outmax}} \times \left(1 - \frac{V_{\text{out}}}{V_{\text{in}}}\right) \times \frac{V_{\text{out}}}{V_{\text{in}}}}{C_{\text{in}} \times f_{\text{SW}}} \quad (22)$$

8.2.2.5 Output Voltage Resistors Selection

The output voltage is set with a resistor divider created by R8 (R_{FBT}) and R6 (R_{FBB}) from the output node to the FB pin. It is recommended to use 1% tolerance or better resistors. For this example design, 6.04 k Ω was selected for R8. Using [公式 23](#), R6 is calculated as 12.08 k Ω . The nearest standard 1% resistor is 12.1 k Ω .

$$R_{\text{FBT}} = R_{\text{FBB}} \times \left(\frac{V_{\text{OUT}}}{V_{\text{REF}}} - 1\right) \quad (23)$$

8.2.2.6 Soft-start Capacitor Selection

The soft-start capacitor determines the amount of time it takes for the output voltage to reach its nominal programmed value during power up. This is useful if a load requires a controlled voltage slew rate. This is also used if the output capacitance is very large and would require large amounts of current to quickly charge the capacitor to the output voltage level. The large currents necessary to charge the capacitor may make the TPS54824 reach its current limit or cause the input voltage rail to sag due excessive current draw from the input power supply. Limiting the output voltage slew rate solves both of these problems. The soft-start capacitor value can be calculated using [公式 24](#). For the example circuit, the soft-start time is not too critical since the output capacitor value is $4 \times 47 \mu\text{F}$ which does not require much current to charge to 1.8 V. The example circuit has the soft-start time set to an arbitrary value of 1 ms which requires a 8.2-nF capacitor.

$$C_{SS} (\text{nF}) = \frac{I_{SS} (\mu\text{A}) \times t_{SS} (\text{ms})}{V_{REF} (\text{V})} = 8.3 \times t_{SS} (\text{ms}) \quad (24)$$

8.2.2.7 Undervoltage Lockout Set Point

The Undervoltage Lockout (UVLO) is adjusted using the external voltage divider network of R2 (R_{ENT}) and R9 (R_{ENB}). The UVLO has two thresholds; one for power up when the input voltage is rising and one for power-down or brown outs when the input voltage is falling. For the example design, the supply should turn on and start switching once the input voltage increases above 4.5 V (UVLO start or enable). After the regulator starts switching, it should continue to do so until the input voltage falls below 4.0 V (UVLO stop or disable). [公式 2](#) and [公式 3](#) can be used to calculate the values for the upper and lower resistor values. For the voltages specified, the standard resistor value used for R2 is 86.6 k Ω and for R4 is 30.9 k Ω .

8.2.2.8 Bootstrap Capacitor Selection

A 0.1- μF ceramic capacitor must be connected between the BOOT to SW pin for proper operation. A 1 Ω to 5.6 Ω resistor can be added in series with the BOOT capacitor to slow down the turn on of the high-side MOSFET. This can reduce voltage spikes on the SW node with the trade off of more power loss and lower efficiency.

8.2.2.9 PGOOD Pull-up Resistor

A 100 k Ω resistor is used to pull-up the power good signal when FB conditions are met. The pull-up voltage source must be less than the 6.5 V absolute maximum of the PGOOD pin.

8.2.2.10 Compensation

There are several methods used to compensate DC - DC regulators. The method presented here is easy to calculate and ignores the effects of the slope compensation internal to the device. Because the slope compensation is ignored, the actual cross-over frequency will usually be lower than the cross-over frequency used in the calculations. This method assumes the cross-over frequency is between the modulator pole and the ESR zero and the ESR zero is at least 10 times greater the modulator pole. This is the case when using low ESR output capacitors. Use the WEBENCH[®] software for more accurate loop compensation. These tools include a more comprehensive model of the control loop.

To get started, the modulator pole, $f_{p\text{mod}}$, and the ESR zero, f_{z1} must be calculated using [公式 25](#) and [公式 26](#). For C_{out} , use a derated value of 116 μF and an ESR of 1 m Ω . Use equations [公式 27](#) and [公式 28](#), to estimate a starting point for the crossover frequency, f_{co} , to design the compensation. For the example design, $f_{p\text{mod}}$ is 6.1 kHz and $f_{z\text{mod}}$ is 1370 kHz. [公式 27](#) is the geometric mean of the modulator pole and the ESR zero. [公式 28](#) is the mean of modulator pole and one half the switching frequency. [公式 27](#) yields 92 kHz and [公式 28](#) gives 46 kHz. Use the lower value of [公式 27](#) or [公式 28](#) for an initial crossover frequency. Next, the compensation components are calculated. A resistor in series with a capacitor is used to create a compensating zero. A capacitor in parallel to these two components forms the compensating pole.

$$f_{p\text{mod}} = \frac{I_{out\text{max}}}{2 \times \pi \times V_{out} \times C_{out}} \quad (25)$$

$$f_{z\text{mod}} = \frac{1}{2 \times \pi \times R_{esr} \times C_{out}} \quad (26)$$

$$f_{CO} = \sqrt{f_{p,mod} \times f_{z,mod}} \quad (27)$$

$$f_{CO} = \sqrt{f_{p,mod} \times \frac{f_{sw}}{2}} \quad (28)$$

To determine the compensation resistor, R5, use 公式 29. R5 is calculated to be 5.71 kΩ and the closest standard value 5.76 kΩ. Use 公式 30 to set the compensation zero to the modulator pole frequency. 公式 30 yields 4500 pF for compensating capacitor C18 and the closest standard value is 4700 pF.

$$R_{COMP} = \left(\frac{2 \times \pi \times f_{CO} \times C_{OUT}}{g_{mPS}} \right) \times \left(\frac{V_{OUT}}{V_{REF} \times g_{mEA}} \right) \quad (29)$$

Where:

- Power stage transconductance, $g_{mPS} = 16 \text{ A/V}$
- $V_{OUT} = 1.8 \text{ V}$
- $V_{REF} = 0.6 \text{ V}$
- Error amplifier transconductance, $g_{mEA} = 1100 \text{ } \mu\text{A/V}$

$$C_{COMP} = \frac{1}{2 \times \pi \times R_{COMP} \times f_{PMOD}} \quad (30)$$

A compensation pole is implemented using an additional capacitor C17 in parallel with the series combination of R5 and C18. This capacitor is recommended to help filter any noise that may couple to the COMP voltage signal. Use the larger value of 公式 31 and 公式 32 to calculate the C17 and to set the compensation pole. C17 is calculated to be the largest of 20 pF and 79 pF. The closest standard value is 82 pF.

$$C_{HF} = \frac{C_{OUT} \times R_{ESR}}{R_{COMP}} \quad (31)$$

$$C_{HF} = \frac{1}{\pi \times R_{COMP} \times f_{SW}} \quad (32)$$

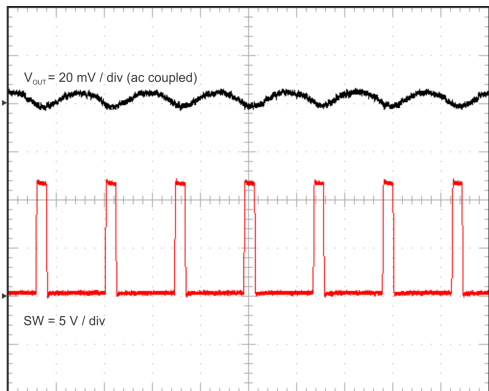

This design example uses type III compensation by adding the feed forward capacitor C19 in parallel with the upper feedback resistor. The use of this capacitor for type III compensation is optional. Type III compensation increases the crossover and adds phase boost above what is possible from type II compensation because it places an additional zero/pole pair. This zero/pole pair is not independent. As a result once the zero location is chosen, the pole is fixed as well. The zero is placed 1.5 times above the intended crossover frequency by calculating the value of C19 with 公式 33. The calculated value is 190 pF and the closest standard value is 180 pF.

$$C_{FF} = \frac{1}{3 \times \pi \times R_{FBT} \times f_{CO}} \quad (33)$$

The initial compensation based on these calculations is R5 = 5.76 kΩ, C18 = 4700 pF, C17 = 82 pF and C19 = 180 pF. These values yield a stable design but after testing the real circuit these values were changed to target a higher crossover frequency to improve transient response performance. The crossover frequency is increased by increasing the value of R5 and decreasing the value of all 3 compensation capacitors. The final values used in this example are R5 = 9.53 kΩ, C18 = 2200 pF, C17 = 27 pF and C19 = 100 pF.

8.2.3 Application Curves

$V_{IN} = 12\text{ V}$ $V_{OUT} = 1.8\text{ V}$ $I_{OUT} = 0\text{ A}$

9 Power Supply Recommendations

The TPS54824 is designed to be powered by a well regulated dc voltage between 4.5 and 17 V. The TPS54824 is a buck converter so the input supply voltage must be greater than the desired output voltage to regulate the output voltage to the desired value. If the input supply voltage is not high enough the output voltage will begin to drop. Input supply current must be appropriate for the desired output current.

10 Layout

10.1 Layout Guidelines

- VIN and PGND traces should be as wide as possible to reduce trace impedance and improve heat dissipation.
- An input capacitor is required on both VIN pins of the IC and must be placed as close as possible to the IC.
- The PGND trace between the output capacitor and the PGND pin should be as wide as possible to minimize its trace impedance.
- Provide sufficient vias for the input capacitor and output capacitor.
- Keep the SW trace as physically short and wide as practical to minimize radiated emissions.
- A separate VOUT path should be connected to the upper feedback resistor.
- Voltage feedback loop should be placed away from the high-voltage switching trace. It is preferable to use ground copper near it as a shield.
- The trace connected to the FB node should be as small as possible to avoid noise coupling.
- Place components connected to the RT/CLK, FB, COMP and SS/TRK pins as close to the IC as possible and minimize traces connected to these pins to avoid noise coupling.
- AGND must be connected to PGND on the PCB. Connect AGND to PGND in a region away from switching currents.

10.2 Layout Example

图 51 through 图 54 shows an example PCB layout and the following list provides a description of each layer.

- The top layer has all components and the main traces for VIN, SW, VOUT and PGND. Both VIN pins are bypassed with two input capacitors placed as close as possible to the IC. Multiple vias are placed near the input and output capacitors. The AGND trace is connected to PGND with a wide trace away from the input capacitors to minimize switching noise.
- Midlayer 1 is used to route the BOOT pin to the BOOT-SW capacitor (CBT). The rest of this layer is covered with PGND.
- Midlayer 2 has a wide trace connecting both VIN pins of the IC. It also has a parallel trace for VOUT to minimize trace resistance. The rest of this layer is covered with PGND.
- The bottom layer has the trace connecting the FB resistor divider to VOUT at the point of regulation. PGND is filled into the rest of this layer to aid with thermal performance.

10.3 Alternate Layout Example

图 55 through 图 58 shows an alternate example PCB layout with unsymmetrical placement of the input capacitors and output capacitors. Both VIN pins are still bypassed with an input capacitor placed as close as possible to the IC.

11 器件和文档支持

11.1 接收文档更新通知

如需接收文档更新通知，请访问 www.ti.com.cn 网站上的器件产品文件夹。点击右上角的提醒我 (Alert me) 注册后，即可每周定期收到已更改的产品信息。有关更改的详细信息，请查阅已修订文档中包含的修订历史记录。

11.2 社区资源

The following links connect to TI community resources. Linked contents are provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

TI E2E™ Online Community *TI's Engineer-to-Engineer (E2E) Community*. Created to foster collaboration among engineers. At e2e.ti.com, you can ask questions, share knowledge, explore ideas and help solve problems with fellow engineers.

Design Support *TI's Design Support* Quickly find helpful E2E forums along with design support tools and contact information for technical support.

11.3 商标

HotRod, E2E are trademarks of Texas Instruments.
WEBENCH is a registered trademark of Texas Instruments.

11.4 静电放电警告

这些装置包含有限的内置 ESD 保护。存储或装卸时，应将导线一起截短或将装置放置于导电泡棉中，以防止 MOS 门极遭受静电损伤。

11.5 Glossary

[SLYZ022](#) — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

12 机械、封装和可订购信息

以下页中包括机械、封装和可订购信息。这些信息是针对指定器件可提供的最新数据。这些数据会在无通知且不对本文档进行修订的情况下发生改变。欲获得该数据表的浏览器版本，请查阅左侧的导航栏。

PACKAGING INFORMATION

Orderable part number	Status (1)	Material type (2)	Package Pins	Package qty Carrier	RoHS (3)	Lead finish/ Ball material (4)	MSL rating/ Peak reflow (5)	Op temp (°C)	Part marking (6)
TPS54824RNVR	Active	Production	VQFN-HR (RNV) 18	3000 LARGE T&R	Yes	Call TI Sn	Level-2-260C-1 YEAR	-40 to 150	54824

TPS54824RNVT.A	Active	Production	VQFN-HR (RNV) 18	250 SMALL T&R	Yes	SN	Level-2-260C-1 YEAR	-40 to 150	54824

(1) **Status:** For more details on status, see our [product life cycle](#).

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
