

TPS56221 4.5V 至 14V 输入大电流同步降压转换器

1 特性

- 输入电压范围：4.5V 至 14V
- 整合功率块技术
- 输出电流高达 25A
- 固定频率选项：300kHz、500kHz 和 1MHz
- 高侧与低侧 MOSFET $R_{DS(on)}$ 感测
- 可编程软启动
- 600mV 基准电压，精度为 1%
- 前馈电压模式控制
- 支持预偏置输出
- 热关断
- 22 引脚 5mm × 6mm PQFN PowerPAD™ 封装

2 应用范围

- 负载点 (POL) 电源模块
- 面向电信和联网应用的高密度 DC-DC 转换器

3 说明

TPS56221 器件是一款高效的大电流同步降压转换器，可由 4.5V 至 14V 范围内的电源供电运行。当负载电流高达 25A 时，该器件可产生低至 0.6V 的输出电压。集成的 NexFET™ 功率 MOSFET 尺寸小且易于使用。

该器件可通过电压前馈补偿实施电压模式控制，能够在输入电压变化时立即做出响应。

TPS56221 采用 22 引脚散热增强型 PQFN (DQP) PowerPAD 封装。

该器件支持高度的设计灵活性，可提供各种用户可编程功能，其中包括软启动、过流保护 (OCP) 电平以及环路补偿。OCP 电平可通过 ILIM 引脚与电路接地之间连接的单个外部电阻进行编程。在初始上电排序过程中，该器件会进入校准周期，测量 ILIM 引脚电压，并设置内部 OCP 电压。在工作期间，器件可在通电时通过将可编程 OCP 电压与低侧 FET 两端的压降进行比较来判断是否为过流状况。之后，器件会进入关断 / 重启周期，直到故障消除为止。

5 Pin Configuration and Functions

Note: The thermal pad is also an electrical ground connection.

Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
BOOT	4	O	Gate drive voltage for the high-side FET. A 100-nF capacitor (typical) must be connected between this pin and the SW pin. To reduce a voltage spike at SW, a BOOT resistor between 5 Ω to 10 Ω may be placed in series with the BOOT capacitor to slow down turnon of the high-side FET.
BP	19	O	Output bypass for the internal regulator. Connect a low-ESR bypass ceramic capacitor of 1 μ F or greater from this pin to GND.
COMP	1	O	Output of the error amplifier and connection node for loop feedback components. Optionally, a 40.2-k Ω resistor from this pin to GND sets switching frequency to 300 kHz instead of the default value of 500 kHz; while a 13.3 k Ω resistor from this pin to GND sets switching frequency to 1 MHz.
EN/SS	21	I	Logic-level input starts or stops the controller via an external user command. Allowing this pin to float turns the controller on. Pulling this pin low disables the controller. This is also the soft-start programming pin. A capacitor connected from this pin to GND programs the soft-start time. The capacitor is charged with an internal current source of 10 μ A. The resulting voltage ramp of this pin is also used as a second noninverting input to the error amplifier after a 0.8 V (typical) level shift downwards. Output regulation is controlled by the internal level shifted voltage ramp until that voltage reaches the internal reference voltage of 600 mV. The voltage ramp of this pin reaches 1.4 V (typical).
FB	2	I	Inverting input to the error amplifier. In normal operation, the voltage on this pin is equal to the internal reference voltage.
GND	3	–	Ground reference for the device.
	5		
GND	Thermal Pad	–	Ground reference for the device. This is also the thermal pad used to conduct heat from the device. This connection serves two purposes. The first is to provide an electrical ground connection for the device. The second is to provide a low thermal impedance path from the device die to the PCB. This pad should be tied externally to a ground plane.
ILIM	18	I	A resistor connected from this pin to GND sets the overcurrent threshold for the device (the low-side FET).
PGD	22	O	Open-drain power good output.
SW	6	I	Switching node of the power conversion stage. Sense line for the adaptive anti-cross conduction circuitry. Acts as the common connection for the flying high-side FET driver.

6 Specifications

6.1 Absolute Maximum Ratings

 over operating free-air temperature range (unless otherwise noted) ⁽¹⁾

		MIN	MAX	UNIT
Voltage	VDD, VIN	–0.3	16.5	V
	SW	–3	25	
	SW (< 100 ns pulse width, 10 μ J)	–5		
	BOOT	–0.3	30	
	BOOT-SW (differential from BOOT to SW)	–0.3	7	
	COMP, PGOOD, FB, BP, EN/SS, ILIM	–0.3	7	
Junction Temperature, T _J		–40	150	°C
Storage temperature, T _{stg}		–55	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other condition beyond those included under *Recommended Operating Conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods of time may affect device reliability.

6.2 ESD Ratings

		VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±1500

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V _{DD}	VIN Input voltage	4.5		14	V
T _J	Operating junction temperature	–40		125	°C

7 Detailed Description

7.1 Overview

The TPS56221 is a 25-A high-performance synchronous buck converter with two integrated N-channel NexFET power MOSFETs. The device implements a voltage-mode control with voltage feed-forward compensation that responds instantly to input voltage change. Prebias capability eliminates concerns about damaging sensitive loads.

7.2 Functional Block Diagram

UDG-11046

7.3 Feature Description

7.3.1 Voltage Reference

The 600-mV bandgap cell is internally connected to the noninverting input of the error amplifier. The reference voltage is trimmed with the error amplifier in a unity gain configuration to remove amplifier offset from the final regulation voltage. The 1% tolerance on the reference voltage allows the user to design a very accurate power supply.

Feature Description (接下页)

图 19. Start-Up Sequence and Timing

7.3.2 Enable Functionality, Start-Up, Sequence, and Timing

After input power is applied, an internal 40- μ A current source begins to charge the soft-start capacitor connected from EN/SS to GND. When the voltage across that capacitor increases to 0.7 V, it enables the internal BP regulator followed by a calibration. Total calibration time is approximately 1.9 ms. See 图 19. During the calibration, the device performs the following two functions.

7.3.2.1 COMP Pin Impedance Sensing

The device samples the impedance at the COMP pin and determines the appropriate operating switching frequency. If there is no resistor connected from the COMP pin to GND, the switching frequency is set to the default value of 500 kHz. If a resistor of 40.2 k Ω $\pm$ 10% is connected from the COMP pin to GND, the switching frequency is set to 300 kHz. Alternatively, if a resistor of 13.3 k Ω $\pm$ 10% is connected from the COMP pin to GND, the switching frequency is set to 1 MHz.

After a 1.1-ms time period, the COMP pin is then brought low for 0.8 ms. This ensures that the feedback loop is preconditioned at start-up and no sudden output rise occurs at the output of the converter when it is allowed to start switching.

7.3.2.2 Overcurrent Protection (OCP) Setting

The device sources 10 μ A (typical) to the resistor connected from the ILIM pin to GND. The voltage developed across that resistor multiplied by a factor of 2 is then sampled and latched off internally as the OCP trip level for the low-side FET until one cycles the input or toggles the EN/SS.

The voltage at EN/SS is internally clamped to 1.3 V before and/or during calibration to minimize the discharging time once calibration is complete. The discharging current is from an internal current source of 140 μ A and it pulls the voltage down to 0.4 V. It then initiates the soft-start by charging up the capacitor using an internal current source of 10 μ A. The resulting voltage ramp on this pin is used as a second noninverting input to the error amplifier after an 800 mV (typical) downward level-shift; therefore, the actual soft-start does not take place until the voltage at this pin reaches 800 mV.

If the EN/SS pin is left floating, the controller starts automatically. EN/SS must be pulled down to less than 270 mV to ensure that the chip is in shutdown mode.

7.3.3 Soft-Start Time

The soft-start time of the TPS56221 is user programmable by selecting a single capacitor. The EN/SS pin sources 10 μ A to charge this capacitor. The actual output ramp-up time is the amount of time that it takes for the 10 μ A to charge the capacitor through a 600 mV range. There is some initial lag due to calibration and an offset (800 mV) from the actual EN/SS pin voltage to the voltage applied to the error amplifier.

Feature Description (接下页)

The soft-start is accomplished in a closed-loop, meaning that the error amplifier controls the output voltage at all times during the soft-start period and the feedback loop is never open as occurs in duty cycle limit soft-start schemes. The error amplifier has two noninverting inputs, one connected to the 600-mV reference voltage, and the other connected to the offset EN/SS pin voltage. The lower of these two voltages is what the error amplifier controls the FB pin to. As the voltage on the EN/SS pin ramps up past approximately 1.4 V (800 mV offset voltage plus the 600 mV reference voltage), the 600-mV reference voltage becomes the dominant input and the converter has reached its final regulation voltage.

The capacitance required for a given soft-start ramp time for the output voltage is calculated in [公式 1](#).

$$C_{SS} = \left(\frac{I_{SS}}{V_{FB}} \right) \times t_{SS}$$

where

- C_{SS} is the required capacitance on the EN/SS pin (nF)
 - I_{SS} is the soft-start source current (10 μ A)
 - V_{FB} is the feedback reference voltage (0.6 V)
 - t_{SS} is the desired soft-start ramp time (ms)
- (1)

7.3.4 Oscillator

The oscillator frequency is internally fixed at 500 kHz if there is no resistor connected from COMP pin to GND. Optionally, a 40.2-k Ω resistor from the COMP pin to GND sets the frequency to 300 kHz. Alternatively, a 13.3-k Ω resistor from COMP pin to GND sets the frequency to 1 MHz.

7.3.5 Overcurrent Protection (OCP)

Programmable OCP level at ILIM is from 6 mV to 50 mV. With a scale factor of 2, the actual OC trip point across the low-side FET is in the range of 12 mV to 100 mV.

If the voltage drop across R_{OCSET} reaches 300 mV during calibration (No R_{OCSET} resistor included), it disables OC protection. Once disabled, there is no low-side or high-side current sensing.

OCP level for the high-side FET is fixed at 54 A (typical). The high-side OCP provides pulse-by-pulse current limiting.

OCP sensing for the low-side FET is a true inductor valley current detection, using sample and hold. [公式 2](#) can be used to calculate R_{OCSET} :

$$R_{OCSET} = \left(I_{OUT(max)} - \left(\frac{I_{P-P}}{2} \right) \right) \times 95 + 62.5$$

where

- I_{P-P} is the peak-to-peak inductor current (A)
 - $I_{OUT(max)}$ is the trip point for OCP (A)
 - R_{OCSET} is the resistor used for setting the OCP level (Ω)
- (2)

An overcurrent (OC) condition is detected by sensing voltage drop across the low-side FET and across the high-side FET. If the voltage drop across either FET exceeds OC threshold, a count increments one count. If no OC condition is detected on either FET, the fault counter decrements by one counter. If three OC pulses are summed, a fault condition is declared which cycles the soft-start function in a hiccup mode. Hiccup mode is defined as four dummy soft-start time-outs followed by a real one if overcurrent condition is encountered during normal operation; or five dummy soft-start time-outs followed by a real one if overcurrent condition occurs from the beginning during start. This cycle continues indefinitely until the fault condition is removed.

Feature Description (接下页)

7.3.6 Switching Node (SW)

The SW pin connects to the switching node of the power conversion stage. It acts as the return path for the high-side gate driver. When configured as a synchronous buck stage, the voltage swing on SW normally traverses from below ground to well above the input voltage. Parasitic inductance in the high-side FET and the output capacitance (C_{OSS}) of both power FETs form a resonant circuit that can produce high frequency (> 100 MHz) ringing on this node. The voltage peak of this ringing, if not controlled, can be significantly higher than the input voltage. Ensure that the peak ringing amplitude does not exceed the absolute maximum rating limit for the pin.

In many cases, a series resistor and capacitor snubber network connected from the switching node to PGND can be helpful in damping the ringing and decreasing the peak amplitude. Provide provisions for snubber network components in the layout of the printed circuit board. If testing reveals that the ringing amplitude at the SW pin exceeds the limit, then include snubber components.

Placing a BOOT resistor with a value from $5\ \Omega$ to $10\ \Omega$ in series with the BOOT capacitor slows down the turnon of the high-side FET and can help to reduce the peak ringing at the switching node.

7.3.7 Input Undervoltage Lockout (UVLO)

The TPS56221 has fixed input UVLO. In order for the device to turn on, the following conditions must be met:

- The EN/SS pin voltage must be greater than V_{IH}
- The input voltage must exceed UVLO on voltage V_{UVLO}

The UVLO has a minimum of 500 mV hysteresis built-in.

7.3.8 Prebias Start-Up

The TPS56221 contains a unique circuit to prevent current from being pulled from the output during start-up in the condition the output is prebiased. There are no PWM pulses until the internal soft-start voltage rises above the error amplifier input (FB pin), if the output is prebiased. Once the soft-start voltage exceeds the error amplifier input, the controller slowly initiates synchronous rectification by starting the synchronous rectifier with a narrow on time. It then increments the on-time on a cycle-by-cycle basis until it coincides with the time dictated by $(1-D)$, where D is the duty cycle of the converter.

This approach prevents the sinking of current from a prebiased output, and ensures the output voltage start-up and ramp to regulation is smooth and controlled.

7.3.9 Power Good

The TPS56221 provides an indication that output is good for the converter. This is an open-drain signal and pulls low when any condition exists that would indicate that the output of the supply might be out of regulation. These conditions include:

- V_{FB} is more than $\pm 12.5\%$ from nominal
- soft-start function is active
- a short-circuit condition has been detected

注

When there is no power to the device, PGOOD cannot pull close to GND if an auxiliary supply is used for the power good indication. In this case, a built-in resistor connected from drain to gate on the PGOOD pulldown device makes the PGOOD pin look approximately like a diode to GND.

7.3.10 Thermal Shutdown

If the junction temperature of the device reaches the thermal shutdown limit of 145°C , both high-side FET and low-side FET are kept off. When the junction cools to the required level (125°C typical), the PWM initiates soft start as during a normal power-up cycle.

7.4 Device Functional Modes

The TPS56221 devices operate in continuous conduction mode (CCM) at a fixed frequency, regardless of the output current. For the first 128 switching cycles, the low-side MOSFET on-time is slowly increased to prevent excessive current sinking in the event the device is started with a prebiased output. Following the first 128 switching cycles, the low-side MOSFET and the high-side MOSFET on-times are fully complementary.

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

The TPS56221 is highly integrated synchronous step-down DC-DC converters. The device is used to convert a higher DC input voltage (4.5 V to 14 V recommended) to a lower DC output voltage (as low as 0.6 V), with a maximum output current of 25 A, for a variety of applications. Use the following design procedure to select key component values for this device.

This design example describes a 25-A, 12-V to 1.0-V design using the TPS56221 high-current integrated buck converter. The system specifications are listed in 表 1.

TP7, TP10	2		Test Point, White, Thru Hole	0.125 x 0.125 inch	5012	
U1	1	QFN-22	4.5-V to 14-V Input, 25-A, synchronous buck converter	6 x 5 mm	TPS56221DQP	TI

8.2.2.1 Switching Frequency Selection

To achieve a balance between small size and high efficiency for this design, use switching frequency of 500 kHz.

8.2.2.2 Inductor Selection

Synchronous buck power inductors are typically sized for between approximately 20% and 40% peak-to-peak ripple current (I_{P-P}).

Using this target ripple current, the required inductor size can be calculated as shown in 公式 3.

$$L \approx \frac{V_{IN(max)} - V_{OUT}}{0.3 \times I_{OUT}} \times \frac{V_{OUT}}{V_{IN(max)}} \times \frac{1}{f_{SW}} = \frac{14V - 1.0V}{0.3 \times 25A} \times \frac{1.0V}{14V} \times \frac{1}{500kHz} = 186nH \quad (3)$$

Selecting a standard 320-nH inductor value, $I_{P-P} = 5.8A$.

The RMS current through the inductor is approximated in 公式 4.

$$I_{L(rms)} = \sqrt{\left(I_{L(avg)}\right)^2 + \left(\frac{1}{12} \times (I_{RIPPLE})^2\right)} = \sqrt{\left(I_{OUT}\right)^2 + \left(\frac{1}{12} \times (I_{P-P})^2\right)} = \sqrt{(25)^2 + \left(\frac{1}{12} \times (5.8)^2\right)} = 25.06A \quad (4)$$

8.2.2.3 Output Capacitor Selection

The selection of the output capacitor is typically driven by the output transient response. For applications with $V_{IN(min)} > 2 \times V_{OUT}$, use overshoot to calculate the minimum output capacitance and the equation is shown in 公式 5.

$$C_{OUT(min)} = \frac{(I_{TRAN})^2 \times L}{V_{OUT} \times V_{OVER}} = \frac{(10)^2 \times 320nH}{1.0 \times 100mV} = 320\mu F \quad (5)$$

For applications where $V_{IN(min)} < 2 \times V_{OUT}$, use undershoot to calculate minimum output capacitance. The equation is shown in 公式 6.

$$C_{OUT(min)} = \frac{(I_{TRAN})^2 \times L}{(V_{IN} - V_{OUT}) \times V_{UNDER}} \quad (6)$$

To meet the low ESR and high-capacitance requirements of this design, five 100-μF, 1210 ceramic capacitors are selected. With a minimum capacitance, the maximum allowable ESR is determined by the maximum ripple voltage and is approximated by 公式 7.

$$ESR_{COUT(max)} = \frac{V_{RIPPLE} - V_{RIPPLE(COUT)}}{I_{P-P}} = \frac{V_{RIPPLE} - \left(\frac{I_{P-P}}{8 \times C_{OUT} \times f_{SW}}\right)}{I_{P-P}} = \frac{20mV - \left(\frac{5.8A}{8 \times 500\mu F \times 500kHz}\right)}{5.8A} = 2.9m\Omega \quad (7)$$

8.2.2.4 Inductor Peak Current Rating

With output capacitance, it is possible to calculate the charge current during start-up and determine the minimum saturation current rating for the inductor. The start-up charging current is approximated by 公式 8.

$$I_{\text{CHARGE}} = \frac{V_{\text{OUT}} \times C_{\text{OUT}}}{t_{\text{SS}}} = \frac{1.0 \text{ V} \times 500 \mu\text{F}}{2 \text{ ms}} = 0.25 \text{ A} \quad (8)$$

The peak current in the inductor $I_{\text{L(peak)}}$ is approximated by 公式 9.

$$I_{\text{L(peak)}} = I_{\text{OUT(max)}} + \left(\frac{1}{2} \times I_{\text{RIPPLE}}\right) + I_{\text{CHARGE}} = 25 \text{ A} + \left(\frac{1}{2} \times 5.8 \text{ A}\right) + 0.25 \text{ A} = 28.2 \text{ A} \quad (9)$$

With the short circuit current trip point $I_{\text{OUT(max)}}$ set at 32 A, the maximum allowable peak current $I_{\text{L(peak max)}}$ is

$$I_{\text{L(peak max)}} = I_{\text{OUT(max)}} + \left(\frac{1}{2} \times I_{\text{RIPPLE}}\right) = 30 \text{ A} + \left(\frac{1}{2} \times 5.8 \text{ A}\right) = 32.9 \text{ A} \quad (10)$$

The selection of output capacitor meets the maximum allowable peak current requirement.

表 3. Inductor Requirements Summary

PARAMETER		VALUE	UNIT
L	Inductance	320	nH
$I_{\text{L(rms)}}$	RMS current (thermal rating)	25.1	A
$I_{\text{L(peak max)}}$	Peak current (saturation rating)	32.9	A

The PA0513.321NLT, 320-nH, 0.32-mΩ, 41-A inductor is selected.

8.2.2.5 Input Capacitor Selection

The input voltage ripple is divided between capacitance and ESR. For this design $V_{\text{IN_RIPPLE(CAP)}} = 150 \text{ mV}$ and $V_{\text{IN_RIPPLE(ESR)}} = 50 \text{ mV}$. The minimum capacitance and maximum ESR are estimated in 公式 11.

$$C_{\text{IN(min)}} = \frac{I_{\text{OUT}} \times V_{\text{OUT}}}{V_{\text{IN_RIPPLE(CAP)}} \times V_{\text{IN(min)}} \times f_{\text{SW}}} = \frac{25 \times 1.0 \text{ V}}{150 \text{ mV} \times 8 \text{ V} \times 500 \text{ kHz}} = 41.7 \mu\text{F} \quad (11)$$

$$\text{ESR}_{\text{CIN(max)}} = \frac{V_{\text{IN_RIPPLE(ESR)}}}{I_{\text{OUT}} + \frac{1}{2}(I_{\text{P-P}})} = \frac{50 \text{ mV}}{25 \text{ A} + \frac{1}{2}(5.8 \text{ A})} = 1.8 \text{ m}\Omega \quad (12)$$

The RMS current in the input capacitors is estimated by 公式 13.

$$I_{\text{RMS(cin)}} = I_{\text{LOAD}} \times \sqrt{D \times (1-D)} = 25 \text{ A} \times \sqrt{\frac{1}{8} \times \left(1 - \frac{1}{8}\right)} = 8.3 \text{ A}_{\text{RMS}} \quad (13)$$

Four 1210, 22-μF, 25-V, X5R ceramic capacitors with about 2.5-mΩ of ESR and a 2.5-A RMS current rating are selected. Higher voltage capacitors are selected to minimize capacitance loss at the DC bias voltage to ensure the capacitors will have sufficient capacitance at the working voltage while a 1.0-μF capacitor in smaller case size is used to reduce high frequency noise from the MOSFET switching.

8.2.2.6 Boot-Strap Capacitor (C14)

The bootstrap capacitor maintains power to the high-side driver during the high-side switch ON time. Per the requirements of the integrated MOSFET, C_{BOOT} is 100 nF with a minimum 10-V rating.

8.2.2.7 Boot-Strap Resistor (R2)

The bootstrap resistor slows the rising edge of the SW voltage to reduce ringing and improve EMI. Per the datasheet recommendation a 5.10-Ω resistor is selected.

8.2.2.7.1 RC Snubber (R9 and C18)

To effectively limit the switch node ringing, a 1.0-Ω resistor and a 2200-pF capacitor are selected.

8.2.2.8 VDD Bypass Capacitor (C11)

In accordance with pin terminations recommended in the data sheet, VDD is bypassed to GND with a 1.0-μF capacitor.

8.2.2.9 BP5 Bypass Capacitor (C12)

Per the datasheet recommended pin terminations, BP5 is bypassed to GND with at least 1.0-μF capacitor. For additional filtering and noise immunity a 4.7-μF capacitor is selected.

8.2.2.10 Soft-Start Capacitor (C13)

The soft-start capacitor provides a constant ramp voltage to the error amplifier to provide controlled, smooth start-up. The soft-start capacitor is sized using 公式 14.

$$C_{SS} = \frac{I_{SS}}{V_{FB}} \times t_{SS} = \frac{10 \mu A}{0.6 V} \times 2.0 ms = 33 nF \quad (14)$$

8.2.2.11 Current Limit (R1)

The TPS56221 uses the negative drop across the internal low-side FET at the end of the OFF-time to measure the valley of the inductor current. Allowing for a minimum of 30% over maximum load, the programming resistor is selected using 公式 15.

$$R_{OCSET} = 95 \times \left(I_{OUT(max)} - \left(\frac{I_{P-P}}{2} \right) \right) + 62.5 \Omega = 95 \times \left(30 A - \left(\frac{5.8 A}{2} \right) \right) + 62.5 \Omega = 2.83 k\Omega \quad (15)$$

A standard 2.87-kΩ resistor is selected from the E-48 series.

8.2.2.12 Feedback Divider (R4, R7)

The TPS56221 converter uses a full operational amplifier with an internally fixed 0.600-V reference. R4 is selected between 10 kΩ and 50 kΩ for a balance of feedback current and noise immunity. With R4 set to 20.5 kΩ, The output voltage is programmed with a resistor divider given by 公式 16.

$$R7 = \frac{V_{FB} \times R4}{(V_{OUT} - V_{FB})} = \frac{0.600 V \times 20.5 k\Omega}{1.0 V - 0.600 V} = 30.8 k\Omega \quad (16)$$

A standard 30.1-kΩ resistor is selected from the E-48 series.

8.2.2.13 Compensation (C15, C16, C17, R3, R6)

Using the *TPS40k Loop Stability Tool* for 50 kHz of bandwidth and 60 degrees of phase margin with an R4 value of 20.5 kΩ, the following values are obtained.

- C17 = C_1 = 680 pF
- C15 = C_2 = 2200 pF
- C16 = C_3 = 100 pF
- R6 = R_2 = 1.00 kΩ
- R3 = R_3 = 7.87 kΩ

8.2.3 Application Curves

9 Power Supply Recommendations

The TPS56221 devices are designed to operate from an input voltage supply between 4.5 V and 14 V. This supply must be well regulated. These devices are not designed for split-rail operation. The VIN and VDD terminals must be the same potential for accurate high-side short circuit protection. Proper bypassing of input supplies and internal regulators is also critical for noise performance, as is PCB layout and grounding scheme. See the recommendations in [Layout Guidelines](#).

10 Layout

10.1 Layout Guidelines

- Place input capacitors next to the VIN pin and on the same side as the device. Use wide and short traces or copper planes for the connection from the VIN pin to the input capacitor and from the input capacitor to the power pad of the device.
- Place the BP decoupling capacitor close to the BP pin and on the same side as the device in order to avoid the use of vias. Use wide and short traces for the connection from the BP pin to the capacitor and from the capacitor to the power pad. If vias are not evitable, use at least three vias to reduce the parasitic inductance.
- Include a Kelvin VDD connection, or separate from VIN connection (bypass input capacitors); add a placeholder for a filter resistor between the VDD pin and the input bus. Place the VDD decoupling capacitor near the VDD pin and on the same side as the device to avoid the use of vias. Use wide and short traces for the connection from the VDD pin to the capacitor and from the capacitor to the power pad of the device. If vias are not avoidable, use at least three vias to reduce the parasitic inductance.
- Maintain the FB trace away from BOOT and SW traces.
- Minimize the area of switch node.
- Use a single ground. Do not use separate signal and power ground.
- Use 3×7 thermal vias as suggested in *Land Pattern Data* in [机械、封装和可订购信息](#).

10.2 Layout Example

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "-" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

- NOTES:
- A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
 - B. This drawing is subject to change without notice.
 - C. Small Outline No-Lead (SON) package configuration.
 - D. The package thermal pad must be soldered to the board for thermal and mechanical performance.
 - E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
-  Pin 1 identifiers are located on both top and bottom of the package and within the zone indicated. The Pin 1 identifiers are either a molded, marked, or metal feature.

THERMAL PAD MECHANICAL DATA

DQP (R-PSON-N22)

PLASTIC SMALL OUTLINE NO-LEAD

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.
