

具有负载断开功能的 TPS61372 16V、3.8A 同步升压转换器

1 特性

- 输入电压范围：2.5V 至 5.5V
- 输出电压范围：高达 16V
- 导通电阻：
 - 低侧 FET - 33mΩ
 - 高侧 FET - 104mΩ
- 开关峰值电流限制：3.8A
- 来自 V_{IN} 的静态电流：74 μA
- 来自 V_{OUT} 的静态电流：10 μA
- 来自 V_{IN} 的关断电流：1 μA
- 开关频率：1.5MHz
- 软启动时间：0.9ms
- 断续输出短路保护
- 可选自动 PFM 和强制 PWM
- 关断期间负载断开
- 外部环路补偿
- 输出过压保护
- 1.57mm × 1.52mm × 0.5mm 16 引脚 WCSP
- 使用 TPS61372 并借助 [WEBENCH® Power Designer](#) 创建定制设计方案

2 应用

- RF PA 驱动器
- NAND 闪存
- 备用电源
- 电机驱动器
- 光学传感器驱动器

3 说明

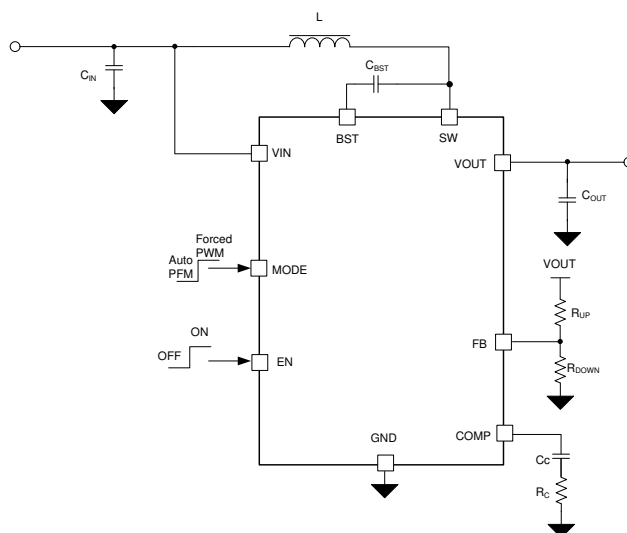

TPS61372 是内置了负载断开功能的完全集成型同步升压转换器。该器件可支持高达 16V 的输出电压（电流限制为 3.8A）。输入电压的范围为 2.5V 至 5.5V，可支持通过单节锂离子电池或 5V 总线供电的应用。

TPS61372 以自适应关断时间控制拓扑为基础采用了峰值电流模式。在中等到重负载条件下，该器件会在 1.5MHz PWM 模式下工作。在轻负载条件下，该器件可通过 MODE 引脚连接配置为自动 PFM 或强制 PWM 模式。自动 PFM 模式的优势是可在轻负载条件下实现高效率，而强制 PWM 模式则可以在整个负载范围内保持恒定开关频率。TPS61372 具有软启动功能，可最大限度地减小启动期间的浪涌电流。TPS61372 可在关断时断开负载，并提供断续模式输出短路保护。此外，该器件还实施了输出过压和热关断保护。TPS61372 可通过 16 引脚 WCSP 1.57mm × 1.52mm × 0.5mm 封装实现紧凑的解决方案尺寸。

5 Pin Configuration and Functions

图 5-1. YKB Package 16-Pin DSBGA (Top View)

表 5-1. Pin Functions

PIN		I/O	DESCRIPTION
NUMBER	NAME		
A1	FB	I	Output voltage feedback. A resistor divider connecting to this pin sets the output voltage.
A2	COMP	O	Output of the internal error amplifier. The loop compensation network must be connected between this pin and GND.
A3	NC	I	No connection. Tie directly to VIN pin. Do not connect with GND or leave it floating.
A4	MODE	I	Operation mode selection pin. MODE = low, the device works in auto PFM mode with good light load efficiency. MODE = high, the device is in forced PWM mode and keeps the switching frequency constant across the whole load range.
B1, B2, B3	GND	-	Ground
B4	EN	I	Enable logic input. Logic high level enables the device. Logic low level disables the device and turns it into shutdown mode.
C1, C2, C3	SW	PWR	The switching node pin of the converter. It is connected to the drain of the internal low-side FET and the source of the internal high-side FET.
C4	BST	O	Power supply for the high-side FET gate driver. A capacitor must be connected between this pin and the SW pin.
D1, D2, D3	VOUT	PWR	Boost converter output
D4	VIN	I	IC power supply input

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
Voltage range at terminals ⁽²⁾	BST	– 0.3	SW+6	V
Voltage range at terminals ⁽²⁾	SW, VOUT	–0.3	19	V
Voltage range at terminals ⁽²⁾	VIN, EN, COMP, FB, MODE, NC	– 0.3	6	V
Operating junction temperature, T _J		– 40	150	°C
Storage temperature, T _{stg}		– 65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) All voltage values are with respect to network ground terminal.

6.2 ESD Ratings

			VALUE	UNIT
V _(ESD) ⁽¹⁾	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽²⁾	±1500	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽³⁾	±500	

- (1) Electrostatic discharge (ESD) to measure device sensitivity and immunity to damage caused by assembly line electrostatic discharges in to the device.
- (2) Level listed above is the passing level per ANSI, ESDA, and JEDEC JS-001. JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process. Manufacturing with less than 500-V HBM is possible with the necessary precautions.
- (3) Level listed above is the passing level per EIA-JEDEC JESD22-C101. JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process. Manufacturing with less than 250-V CDM is possible with the necessary precautions.

6.3 Recommended Operating Conditions

Over operating free-air temperature range unless otherwise noted.

		MIN	NOM	MAX	UNIT
V _{IN}	Input voltage	2.5		5.5	V
V _{OUT}	Output voltage	5		16	V
T _J	Operating junction temperature	– 40		125	°C

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾		TPS61372	UNIT
		YKB	
		16 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	87.1	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	0.7	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	24.1	°C/W
ψ_{JT}	Junction-to-top characterization parameter	0.4	°C/W
ψ_{JB}	Junction-to-board characterization parameter	24.3	°C/W

(1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report, SPRA953.

6.5 Electrical Characteristics

V_{IN} = 2.5 V to 5.5 V and V_{OUT} = 5 V to 16 V, T_J = - 40°C to 125°C, Typical values are at T_J = 25°C, unless otherwise noted.

PARAMETER		TEST CONDITION	MIN	TYP	MAX	UNIT
POWER SUPPLY						
V_{IN_UVLO}	Input voltage under voltage lockout (UVLO) threshold, rising	$V_{OUT} = 12\text{ V}$, $T_J = -40^\circ\text{C}$ to 125°C			2.32	V
	Input voltage under voltage lockout (UVLO) threshold, falling				2.1	V
I_Q	Quiescent current into VIN pin	IC enabled, no switching $T_J = -40^\circ\text{C}$ to 85°C		74	110	μA
I_Q	Quiescent current into VOUT pin	IC enabled, no switching, $V_{IN} = 2.5\text{ V}$, $V_{OUT} = 5\text{ V}$ to 16 V , $T_J = -40^\circ\text{C}$ to 85°C		10	26	μA
I_{SD}	Shutdown current from VIN to GND	$V_{IN} = 2.5\text{ V}$ to 5.5 V , $V_{OUT} = SW = 0\text{ V}$, $EN = 0$, $T_J = -40^\circ\text{C}$ to 85°C		0.03	1	μA
OUTPUT VOLTAGE						
V_{REF}	Reference voltage on FB pin		0.585	0.594	0.603	V
	AUTO PFM mode	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$		1.016		V_{REF}
I_{FB_LKG}	Leakage current into FB pin				30	nA
POWER SWITCHES						
$R_{DS(on)}$	Low-side FET on resistance	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$		33		mΩ
	High-side + Dis connect FET on resistance	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$		104		mΩ
CURRENT LIMIT						
I_{LIM}	Current Limit (Auto PFM)	$V_{IN} = 3\text{ V}$ to 4.5 V , $V_{OUT} = 5\text{ V}$ to 16 V , $T_J = -40^\circ\text{C}$ to 125°C	3.4	3.8	4.3	A
	Current Limit (Forced PWM)	$V_{IN} = 3\text{ V}$ to 4.5 V , $V_{OUT} = 5\text{ V}$ to 16 V , $T_J = -40^\circ\text{C}$ to 125°C	3.28	3.6	4.0	A
EN, MODE LOGICS						
V_{IH}	EN, MODE pin high level input voltage				1.2	V
V_{IL}	EN, MODE pin low level input voltage		0.4			V
V_{HYS}	EN, MODE pin Hysteresis			100		mV
$T_{DEGLITCH}$	EN, MODE deglitch time rising / falling	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$		13		μS
R_{PD}	EN, MODE pull down resistor	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$		800		kΩ
SWITCHING CHARACTER						

$V_{IN} = 2.5\text{ V to }5.5\text{ V}$ and $V_{OUT} = 5\text{ V to }16\text{ V}$, $T_J = -40^\circ\text{C to }125^\circ\text{C}$, Typical values are at $T_J = 25^\circ\text{C}$, unless otherwise noted.

PARAMETER		TEST CONDITION	MIN	TYP	MAX	UNIT
f_{SW}	Switch frequency	$V_{IN} = 3\text{ V to }4.5\text{ V}$, $V_{OUT} = 5\text{ V to }12\text{ V}$, $T_J = -40^\circ\text{C to }125^\circ\text{C}$	1.2		1.7	MHz
f_{SW_FOLD}	Switch frequency foldback	$V_{IN} = 4\text{ V}$, $T_J = -40^\circ\text{C to }125^\circ\text{C}$	470	535	600	kHz
V_{FSW_LOW}	Threshold for fsw foldback (1.5 MHz normal)	$V_{IN} = 4\text{ V}$, $T_J = -40^\circ\text{C to }125^\circ\text{C}$	15%	20%	25%	V_{IN}
$V_{FSW_LOW_HSY}$	Hysteresis for fsw foldback	$V_{IN} = 4\text{ V}$, $T_J = 25^\circ\text{C}$		150		mV

TIMING

t_{ON_MIN}	Minimum on time	$V_{IN} = 4\text{ V}$, $T_J = -40^\circ\text{C to }125^\circ\text{C}$		75	95	ns
t_{SS}	Soft-start time	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$		0.9		ms
t_{HIC_ON}	Off time of hiccup cycle	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$		74		ms
t_{HIC_OFF}	On time of hiccup cycle	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$		1.9		ms

ERROR AMPLIFIER

V_{COMP}	COMP output high voltage Auto PFM	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$, $V_{FB} = V_{REF} - 200\text{mV}$		1.4		V
	COMP output high voltage Forced PWM	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$, $V_{FB} = V_{REF} - 200\text{mV}$		1.5		V
V_{COMPL}	COMP output low voltage Auto PFM	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$, $V_{FB} = V_{REF} + 200\text{mV}$		0.8		V
	COMP output low voltage Forced PWM	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$, $V_{FB} = V_{REF} + 200\text{mV}$		0.6		V
Gm	Error amplifier trans conductance	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$		175		μS
I_{SINK_EA}	Sink current of COMP	$V_{IN} = 4\text{ V}$, $T_J = 25^\circ\text{C}$, $V_{FB} = V_{REF} + 200\text{mV}$		20		μA
I_{SOURCE_EA}	Source current of COMP	$V_{IN} = 4\text{ V}$, $T_J = 25^\circ\text{C}$, $V_{FB} = V_{REF} - 200\text{mV}$		20		μA

PROTECTION

V_{OVP}	Output over-voltage protection threshold	$V_{IN} = 2.5\text{ V to }5.5\text{ V}$, $T_J = -40^\circ\text{C to }125^\circ\text{C}$	16.5	17.3	18	V
V_{OVP_HYS}	Output over-voltage protection hysteresis	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$, $T_J = 25^\circ\text{C}$		500		mV

THERMAL

T_{SD}	Thermal shutdown threshold	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$		140		$^\circ\text{C}$
T_{SD_HYS}	Thermal shutdown hysteresis	$V_{IN} = 4\text{ V}$, $V_{OUT} = 12\text{ V}$		20		$^\circ\text{C}$

7 Detailed Description

7.1 Overview

The TPS61372 is a highly-integrated synchronous boost converter to support 16-V output with load disconnect and short protection built-in. The TPS61372 supports input voltage ranging from 2.5 V to 5.5 V. The TPS61372 uses the peak current mode with adaptive off-time control topology to regulate the output voltage. The TPS61372 operates at a quasi-constant frequency pulse-width modulation (PWM) at moderate to heavy load current. At the beginning of each cycle, the low-side FET turns on and the inductor current ramps up to reach a peak current determined by the output of the error amplifier (EA). When the peak current pre-set value determined by the output trips of the EA, the low-side FET turns off. As long as the low-side FET turns off, the high-side FET turns on after a short delay time to avoid the shoot through. The duration of low-side FET off state is determined by the V_{IN} / V_{OUT} ratio.

High efficiency is achieved at light load as the TPS61372 operates in PFM operation. The device can be also configured at forced PWM mode to keep the frequency constant across the whole load range and to have more immunity against noise sensitive applications.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Undervoltage Lockout

The undervoltage lockout (UVLO) circuit prevents the device from malfunctioning at the low input voltage of the battery from the excessive discharge. The device starts operation once the rising V_{IN} trips the UVLO threshold and it disables the output stage of the converter once V_{IN} is below the UVLO falling threshold.

7.3.2 Enable and Disable

When the input voltage is above the UVLO threshold and the EN pin is pulled above the high threshold (1.2 V minimum), the TPS61372 is enabled. When the EN pin is pulled below the low threshold (0.4 V maximum), the TPS61372 goes into shutdown mode.

7.3.3 Error Amplifier

The TPS61372 has a transconductance amplifier and compares the feedback voltage with the internal voltage reference (or the internal soft-start voltage during start-up phase). The transconductance of the error amplifier is 175 $\mu\text{A} / \text{V}$ typically. The loop compensation components are placed between the COMP terminal and ground to optimize the loop stability and response speed.

7.3.4 Bootstrap Voltage (BST)

The TPS61372 has an integrated bootstrap regulator and requires a small ceramic capacitor between the BST and SW pin to provide the gate drive voltage for the high-side FET. The recommended value for this ceramic capacitor is between 20 nF to 200 nF.

7.3.5 Load Disconnect

The TPS61372 device provides a load disconnect function, which completely disconnects the output from the input during shutdown or fault conditions.

7.3.6 Overvoltage Protection

If the output voltage is detected above the overvoltage protection threshold (typically 17.3 V), the TPS61372 stops switching immediately until the voltage at the V_{OUT} pin drops below the output overvoltage protection recovery threshold (with 500-mV hysteresis). This function prevents the devices against the overvoltage and secures the circuits connected with the output of excessive overvoltage.

7.3.7 Thermal Shutdown

A thermal shutdown is implemented to prevent the damage due to the excessive heat and power dissipation. Typically, the thermal shutdown occurs at the junction temperature exceeding 140°C (typical). When the thermal shutdown is triggered, the device stops switching and recovers when the junction temperature falls below 120°C (typical).

7.3.8 Start-Up

The TPS61372 implements the soft start function to reduce the inrush current during start-up. The TPS61372 begins soft start when the EN pin is pulled high. There are two phases for the start-up procedure:

- When V_{OUT} is below 120% V_{IN} , the output voltage ramps up with the switching frequency of 535 kHz (typical).
- When V_{OUT} exceeds 120% V_{IN} , the switching frequency changes to 1.5 MHz typically and ramps up the output voltage to the setpoint.

7.3.9 Short Protection

The TPS61372 provides a hiccup protection mode when output short protection occurs. In hiccup mode, the TPS61372 shuts down after the 1.9-ms duration of current limit is triggered and the V_{OUT} is pulled below 105% V_{IN} . In hiccup steady state, the device shuts down itself and restarts after a 74-ms (typical) waiting time, which helps to reduce the overall thermal dissipation at continuous short condition. After the short condition releases, the device can recover automatically and restart the start-up phase.

7.4 Device Functional Modes

7.4.1 Operation

In light load condition, the TPS61372 can be configured at Auto PFM or Forced PWM. At Auto PFM operation, the switching frequency is lowered at light load and features higher efficiency, while for Forced PWM operation, the frequency keeps constant across the whole load range.

7.4.2 Auto PFM Mode

The TPS61372 integrates a power-save mode with pulse frequency modulation (PFM) at light load (set the mode pin low logic or floating). The device skips the switching cycles and regulates the output voltage at a higher threshold (typically $101.6\% \times V_{OUT_NORM}$). 图 7-1 shows the working principle of the PFM operation. The auto PFM mode reduces the switching losses and improves efficiency at light load condition by reducing the average switching frequency.

图 7-1. Auto PFM Operation Behavior

7.4.3 Forced PWM Mode

In forced PWM mode, the TPS61372 keeps the switching frequency constant across the whole load range. When the load current decreases, the output of the internal error amplifier decreases as well to lower the inductor peak current and delivers less power. The high-side FET is not turned off even if the current through the FET goes negative to keep the switching frequency be the same as that of the heavy load.

7.4.4 Mode Selectable

There is a mode pin to configure the TPS61372 into two different operation modes. The device works in auto PFM mode when pulling the mode pin to low or floating and in forced PWM mode when mode pin is high.

8 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

8.1 Application Information

The TPS61372 is a synchronous boost converter. The following design procedure can be used to select component values for the TPS61372. This section presents a simplified discussion of the design process. Alternately, the WEBENCH® software may be used to generate a complete design. The WEBENCH® software uses an interactive design procedure and accesses a comprehensive database of components when generating a design. This section presents a simplified discussion of the design process.

8.2 Typical Application

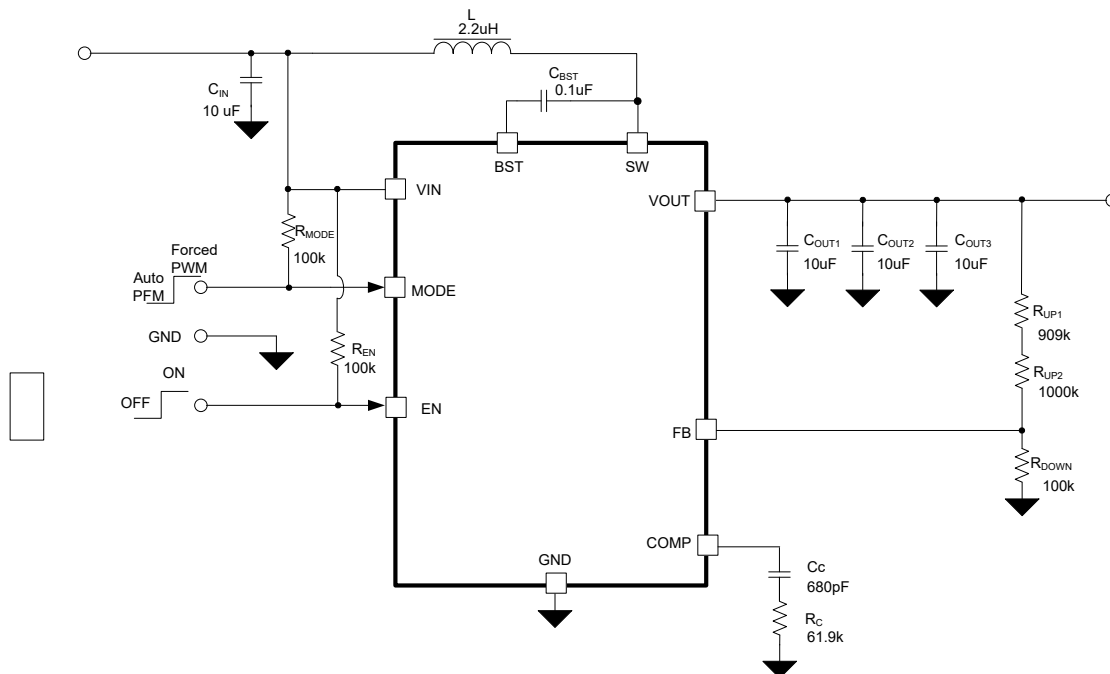

图 8-1. TPS61372 12-V Output With Load Disconnect Schematic

8.2.1 Design Requirements

For this design example, use 表 8-1 as the design parameters.

表 8-1. Design Parameters

PARAMETER	VALUE
Input voltage range	3 V to 5 V
Output voltage	12 V
Output ripple voltage	± 3%
Output current	0.4 A
Operating frequency	1.5 MHz

8.2.2 Detailed Design Procedure

8.2.2.1 Custom Design With WEBENCH® Tools

[Click here](#) to create a custom design using the TPS61372 device with the WEBENCH® Power Designer.

1. Start by entering the input voltage (V_{IN}), output voltage (V_{OUT}), and output current (I_{OUT}) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:

- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at www.ti.com/WEBENCH.

To begin the design process a few parameters must be decided upon. The designer needs to know the following:

- Input voltage range
- Output voltage
- Output ripple voltage
- Output current rating
- Operating frequency

8.2.2.2 Setting the Output Voltage

The output voltage of the TPS61372 is externally adjustable using a resistor divider network. The relationship between the output voltage and the resistor divider is given by 方程式 1.

$$V_{OUT} = V_{FB} \times \left(1 + \frac{R_{UP}}{R_{DOWN}}\right) \quad (1)$$

where

- V_{OUT} is the output voltage
- R_{UP} is the top divider resistor
- R_{DOWN} is the bottom divider resistor

Choose R_{DOWN} to be approximately 100 k Ω . Slightly increasing or decreasing R_{DOWN} can result in closer output voltage matching when using standard value resistors. In this design, $R_{DOWN} = 100$ k Ω and $R_{UP} = 1.909$ M Ω (1 M Ω + 909 k Ω), resulting in an output voltage of 12 V.

For the best accuracy, TI recommends R_{DOWN} to be around 100 k Ω to ensure that the current following through R_{DOWN} is at least 100 times larger than FB pin leakage current. Changing R_{DOWN} towards the lower value increases the robustness against noise injection. Changing R_{DOWN} towards the higher values reduces the quiescent current for achieving higher efficiency at the light load currents.

8.2.2.3 Selecting the Inductor

A boost converter normally requires two main passive components for storing the energy during power conversion: an inductor and an output capacitor. The inductor affects the steady state efficiency (including the ripple and efficiency) as well as the transient behavior and loop stability, which makes the inductor to be the most critical component in application.

When selecting the inductor, as well as the inductance, the other parameters of importance are:

- The maximum current rating (RMS and peak current should be considered)
- The series resistance
- Operating temperature

Choosing the inductor ripple current with the low ripple percentage of the average inductor current results in a larger inductance value, maximizes the potential output current of the converter, and minimizes EMI. The larger ripple results in a smaller inductance value and a physically smaller inductor, which improves transient response, but results in potentially higher EMI.

The rule of thumb in choosing the inductor is to make sure the inductor ripple current (ΔI_L) is a certain percentage of the average current. The inductance can be calculated by [方程式 2](#), [方程式 3](#), and [方程式 4](#):

$$\Delta I_L = \frac{V_{\text{IN}} \times D}{L \times f_{\text{SW}}} \quad (2)$$

$$\Delta I_{L_R} = \text{Ripple\%} \times \frac{V_{\text{OUT}} \times I_{\text{OUT}}}{\eta \times V_{\text{IN}}} \quad (3)$$

$$L = \frac{1}{\text{Ripple \%}} \times \frac{\eta \times V_{\text{IN}}}{V_{\text{OUT}} \times I_{\text{OUT}}} \times \frac{V_{\text{IN}} \times D}{f_{\text{SW}}} \quad (4)$$

where

- ΔI_L is the peak-peak inductor current ripple
- V_{IN} is the input voltage
- D is the duty cycle
- L is the inductor
- f_{SW} is the switching frequency
- Ripple% is the ripple ration versus the DC current
- V_{OUT} is the output voltage
- I_{OUT} is the output current
- η is the efficiency

The current flowing through the inductor is the inductor ripple current plus the average input current. During power up, load faults, or transient load conditions, the inductor current can increase above the peak inductor current calculated.

Inductor values can have $\pm 20\%$ or even $\pm 30\%$ tolerance with no current bias. When the inductor current approaches the saturation level, its inductance can decrease 20% to 35% from the value at 0-A bias current depending on how the inductor vendor defines saturation. When selecting an inductor, make sure its rated current, especially the saturation current, is larger than its peak current during the operation.

The inductor peak current varies as a function of the load, the switching frequency, and the input and output voltages and it can be calculated by [方程式 5](#) and [方程式 6](#).

$$I_{PEAK} = I_{IN} + \frac{1}{2} \times \Delta I_L \quad (5)$$

where

- I_{PEAK} is the peak current of the inductor
- I_{IN} is the input average current
- ΔI_L is the ripple current of the inductor

The input DC current is determined by the output voltage, the output current, and efficiency can be calculated by:

$$I_{IN} = \frac{V_{OUT} \times I_{OUT}}{V_{IN} \times \eta} \quad (6)$$

where

- I_{IN} is the input current of the inductor
- V_{OUT} is the output voltage
- V_{IN} is the input voltage
- η is the efficiency

While the inductor ripple current depends on the inductance, the frequency, the input voltage, and duty cycle calculated by [方程式 2](#), replace [方程式 2](#), [方程式 6](#) into [方程式 5](#) to calculate the inductor peak current:

$$I_{PEAK} = \frac{I_{OUT}}{(1-D) \times \eta} + \frac{1}{2} \times \frac{V_{IN} \times D}{L \times f_{SW}} \quad (7)$$

where

- I_{PEAK} is the peak current of the inductor
- I_{OUT} is the output current
- D is the duty cycle
- η is the efficiency
- V_{IN} is the input voltage
- L is the inductor
- f_{SW} is the switching frequency

The heat rating current (RMS) is calculated by [方程式 8](#):

$$I_{L_RMS} = \sqrt{I_{IN}^2 + \frac{1}{12} (\Delta I_L)^2} \quad (8)$$

where

- I_{L_RMS} is the RMS current of the inductor
- I_{IN} is the input current of the inductor
- ΔI_L is the ripple current of the inductor

It is important that the peak current does not exceed the inductor saturation current and the RMS current is not over the temperature related rating current of the inductors.

For a given physical inductor size, increasing inductance usually results in an inductor with lower saturation current. The total losses of the coil consists of the DC resistance (DCR) loss and the following frequency dependent loss:

- The losses in the core material (magnetic hysteresis loss, especially at high switching frequencies)
- Additional losses in the conductor from the skin effect (current displacement at high frequencies)
- Magnetic field losses of the neighboring windings (proximity effect)

For a certain inductor, the larger current ripple (smaller inductor) generates the higher DC and frequency-dependent loss. An inductor with lower DCR is basically recommended for higher efficiency. However, it is usually a tradeoff between the loss and footprint.

The following inductor series in 表 8-2 from the different suppliers are recommended.

表 8-2. Recommended Inductors for TPS61372

PART NUMBER	L (μH)	DCR Typ (mΩ) TYP.	SATURATION CURRENT / TYP.	SIZE (L × W × H mm)	VENDOR ⁽¹⁾

8.2.2.4 Selecting the Output Capacitors

The output capacitor is mainly selected to meet the requirements at load transient or steady state. Then the loop is compensated for the output capacitor selected. The output ripple voltage is related to the equivalent series resistance (ESR) of the capacitor and its capacitance. Assuming a capacitor with zero ESR, the minimum capacitance needed for a given ripple can be calculated by 方程式 9:

$$C_{OUT} = \frac{I_{OUT} \times (V_{OUT} - V_{IN})}{f_{SW} \times \Delta V \times V_{OUT}} \quad (9)$$

where

- C_{OUT} is the output capacitor
- I_{OUT} is the output current
- V_{OUT} is the output voltage
- V_{IN} is the input voltage
- ΔV is the output voltage ripple required
- f_{SW} is the switching frequency

The additional output ripple component caused by ESR is calculated by 方程式 10:

$$\Delta V_{ESR} = I_{OUT} \times R_{ESR} \quad (10)$$

where

- ΔV_{ESR} is the output voltage ripple caused by ESR
- R_{ESR} is the resistor in series with the output capacitor

For the ceramic capacitor, the ESR ripple can be neglected. However, for the tantalum or electrolytic capacitors, it must be considered if used.

Care must be taken when evaluating the rating of a ceramic capacitor under the DC bias. Ceramic capacitors can derate by as much as 70% of its capacitance at its rated voltage. Therefore, enough margins on the voltage rating should be considered to ensure adequate capacitance at the required output voltage.

表 8-3. Recommended Output Capacitor for TPS61372

PART NUMBER	C (μF)	PIECES	DESCRIPTION	SIZE	VENDOR ⁽¹⁾
GRM188R61E106MA73D	10	3	X5R, 0603, 5 V, ±20% tolerance	0603	Murata

8.2.2.5 Selecting the Input Capacitors

Multilayer ceramic capacitors are an excellent choice for the input decoupling of the step-up converter as they have extremely low ESR and are available in small footprints. Input capacitors should be located as close as possible to the device.

Take care when using only ceramic input capacitors. When a ceramic capacitor is used at the input and the power is being supplied through long wires, such as from a wall adapter, a load step at the output can induce ringing at the V_{IN} pin. This ringing can couple to the output and be mistaken as loop instability or can even damage the part. Place additional "bulk" capacitance (electrolytic or tantalum) in this circumstance, between C_{IN} and the power source lead, to reduce ringing that can occur between the inductance of the power source leads and C_{IN} .

8.2.2.6 Loop Stability and Compensation

8.2.2.6.1 Small Signal Model

The TPS61372 uses the peak current with adaptive off-time control topology. With the inductor current information sensed, the small-signal model of the power stage reduces from a two-pole system, created by L and C_{OUT} , to a single-pole system, created by R_{OUT} and C_{OUT} . An external loop compensation network connecting to the COMP pin of TPS61372 is added to optimize the loop stability and the response time, a resistor R_C , capacitor C_C , and C_P shown in 图 8-2 comprises the loop compensation network.

图 8-2. TPS61372 Control Equivalent Circuitry Model

The small signal of power stage including the slope compensation is:

$$G_{PS}(S) = \frac{R_{OUT} \times (1-D)}{2 \times R_{SENSE}} \times \frac{\left(1 + \frac{S}{2\pi \times f_{ESR}}\right) \left(1 - \frac{S}{2\pi \times f_{RHP}}\right)}{1 + \frac{S}{2\pi \times f_p}} \quad (11)$$

where

- D is the duty cycle
- R_{OUT} is the output load resistor
- R_{SENSE} is the equivalent internal current sense resistor, which is typically $0.2 \, \Omega$ of TPS61372

The single pole of the power stage is:

$$f_P = \frac{2}{2\pi \times R_{OUT} \times C_{OUT}} \quad (12)$$

where

- C_{OUT} is the output capacitance, for a boost converter having multiple, identical output capacitors in parallel, simply combine the capacitors with the equivalent capacitance

The zero created by the ESR of the output capacitor is:

$$f_{ESR} = \frac{1}{2\pi \times R_{ESR} \times C_{OUT}} \quad (13)$$

where

- R_{ESR} is the equivalent resistance in series of the output capacitor

The right-hand plane zero is:

$$f_{RHP} = \frac{R_{OUT} \times (1-D)^2}{2\pi \times L} \quad (14)$$

where

- D is the duty cycle
- R_{OUT} is the output load resistor
- L is the inductance

The TPS61372 COMP pin is the output of the internal trans-conductance amplifier.

方程式 15 shows the equation for feedback resistor network and the error amplifier.

$$H_{EA}(S) = G_{EA} \times R_{EA} \times \frac{R_{DOWN}}{R_{UP} + R_{DOWN}} \times \frac{1 + \frac{S}{2 \times \pi \times f_Z}}{\left(1 + \frac{S}{2 \times \pi \times f_{P1}}\right) \times \left(1 + \frac{S}{2 \times \pi \times f_{P2}}\right)} \quad (15)$$

where

- R_{EA} is the output impedance of the error amplifier $R_{EA} = 500 \text{ M}\Omega$. G_{EA} is the transconductance of the error amplifier, $G_{EA} = 175 \text{ }\mu\text{S}$.
- f_{P1} , f_{P2} is the pole's frequency of the compensation
- f_Z is the zero's frequency of the compensation network

$$f_{P1} = \frac{1}{2\pi \times R_{EA} \times C_C} \quad (16)$$

where

- C_C is the zero capacitor compensation

$$f_{P2} = \frac{1}{2\pi \times R_C \times C_P} \quad (17)$$

where

- C_P is the pole capacitor compensation

- R_C is the resistor of the compensation network

$$f_z = \frac{1}{2\pi \times R_C \times C_C} \quad (18)$$

8.2.2.7 Loop Compensation Design Steps

With the small signal models coming out, the next step is to calculate the compensation network parameters with the given inductor and output capacitance.

1. Set the Crossover Frequency, f_C .

- The first step is to set the loop crossover frequency, f_C . The higher crossover frequency, the faster the loop response is. It is generally accepted that the loop gain cross over no higher than the lower of either 1/10 of the switching frequency, f_{SW} , or 1/5 of the RHPZ frequency, f_{RHPZ} . Then calculate the loop compensation network values of R_C , C_C , and C_p in following sections.

2. Set the Compensation Resistor, R_C .

- By placing f_z below f_C , for frequencies above f_C , $R_C \parallel R_{EA}$ approximately = R_C , so $R_C \times G_{EA}$ sets the compensation gain. Setting the compensation gain, $K_{COMP-dB}$, at f_z , results in the total loop gain, $T(s) = G_{PS(s)} \times H_{EA(s)} \times H_e(s)$ being zero at f_C .
- Therefore, to approximate a single-pole rolloff up to f_{P2} , rearrange 方程式 19 to solve for R_C so that the compensation gain, K_{EA} , at f_C is the negative of the gain, K_{PS} , read at frequency f_C for the power stage bode plot or more simply:

$$K_{EA}(f_C) = 20 \times \log(G_{EA} \times R_C \times \frac{R_{DOWN}}{R_{UP} + R_{DOWN}}) = -K_{PS}(f_C) \quad (19)$$

where

- K_{EA} is gain of the error amplifier network
- K_{PS} is the gain of the power stage
- G_{EA} is the transconductance of the amplifier, the typical value of $G_{EA} = 175 \mu A / V$

3. Set the compensation zero capacitor, C_C .

- Place the compensation zero at the power stage pole position of R_{OUT} , C_{OUT} to get:

$$f_z = \frac{1}{2\pi \times R_C \times C_C} \quad (20)$$

- Set $f_z = f_P$, and get:

$$C_C = \frac{R_{OUT} \times C_{OUT}}{2R_C} \quad (21)$$

4. Set the compensation pole capacitor, C_p .

- Place the compensation pole at the zero produced by the R_{ESR} and the C_{OUT} . It is useful for canceling unhelpful effects of the ESR zero.

$$f_{P2} = \frac{1}{2\pi \times R_C \times C_P} \quad (22)$$

$$f_{ESR} = \frac{1}{2\pi \times R_{ESR} \times C_{OUT}} \quad (23)$$

- Set $f_{P2} = f_{ESR}$, and get:

$$C_P = \frac{R_{ESR} \times C_{OUT}}{R_C} \quad (24)$$

- If the calculated value of C_P is less than 10 pF, it can be neglected.

Designing the loop for greater than 45° of phase margin and greater than 6-dB gain margin eliminates output voltage ringing during the line and load transient. The $R_C = 61.9 \text{ k}\Omega$, $C_C = 680 \text{ pF}$ for this design example.

8.2.2.8 Selecting the Bootstrap Capacitor

The bootstrap capacitor between the BST and SW pin supplies the gate current to charge the high-side FET device gate during the turnon of each cycle and also supplies charge for the bootstrap capacitor. The recommended value of the bootstrap capacitor is 20 nF to 200 nF. C_{BST} should be a good quality, low-ESR ceramic capacitor located at the pins of the device to minimize potentially damaging voltage transients caused by trace inductance. A value of 100 nF is selected for this design example.

8.2.3 Application Curves

Typical condition $V_{IN} = 3\text{ V}$ to 5 V , $V_{OUT} = 12\text{ V}$, temperature = 25°C , unless otherwise noted

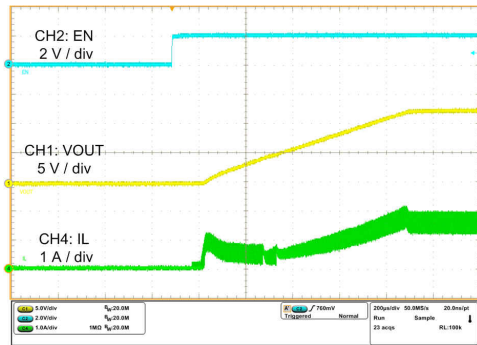

$V_{IN} = 4\text{ V}$ $V_{OUT} = 12\text{ V}$ Mode = Auto PFM
 $L = 2.2\text{ }\mu\text{H}$ $C_{OUT} = 3 \times 10\text{ }\mu\text{F}$

图 8-3. Steady-State at 200-mA Load

$V_{IN} = 4\text{ V}$ $V_{OUT} = 12\text{ V}$ Mode = Auto PFM
 $L = 2.2\text{ }\mu\text{H}$ $C_{OUT} = 3 \times 10\text{ }\mu\text{F}$

图 8-4. Steady-State at 10-mA Load

$V_{IN} = 4\text{ V}$ $V_{OUT} = 12\text{ V}$ Mode = Auto PFM
 $L = 2.2\text{ }\mu\text{H}$ $C_{OUT} = 3 \times 10\text{ }\mu\text{F}$

图 8-5. Start-Up by EN, Load = $12.5\text{ }\Omega$

$V_{IN} = 4\text{ V}$ $V_{OUT} = 12\text{ V}$ Mode = Auto PFM

 $L = 2.2\text{ }\mu\text{H}$ $C_{OUT} = 3 \times 10\text{ }\mu\text{F}$

图 8-8. Shorted Output

9 Power Supply Recommendations

The devices are designed to operate from an input voltage supply ranging from 2.5 V to 5.5 V . This input supply must be well regulated. If the input supply is located more than a few inches from the TPS61372, the bulk

capacitance can be required in addition to the ceramic bypass capacitors. An electrolytic capacitor with a value of 47 μF is a typical choice.

10 Layout

10.1 Layout Guidelines

The basic PCB board layout requires a separation of sensitive signal and power paths. If the layout is not carefully done, the regulator can suffer from the instability or noise problems.

The following checklist is suggested that be followed to get good performance for a well-designed board:

1. Minimize the high current path from output of chip, the output capacitor to the GND of chip. This loop contains high di/dt switching currents (nano seconds per ampere) and easy to transduce the high frequency noise.
2. Minimize the length and area of all traces connected to the SW pin, and always use a ground plane under the switching regulator to minimize inter plane coupling.
3. Use a combination of bulk capacitors and smaller ceramic capacitors with low series resistance for the input and output capacitors. Place the smaller capacitors closer to the IC to provide a low impedance path for decoupling the noise.
4. The ground area near the IC must provide adequate heat dissipating area. Connect the wide power bus (for example, V_{OUT} , SW, GND) to the large area of copper, or to the bottom or internal layer ground plane, using vias for enhanced thermal dissipation.
5. Place the input capacitor being close to the V_{IN} pin and the PGND pin in order to reduce the input supply ripple.
6. Place the noise sensitive network like the feedback and compensation being far away from the SW trace.
7. Use a separate ground trace to connect the feedback and the loop compensation circuitry. Connect this ground trace to the main power ground at a single point to minimize circulating currents.

10.2 Layout Example

图 10-1. Recommended Layout

10.2.1 Thermal Considerations

Implementation of integrated circuits in low-profile and fine-pitch surface-mount packages typically requires special attention to power dissipation. Many system-dependent issues such as thermal coupling, airflow, added heat sinks and convection surfaces, and the presence of other heat-generating components affect the power dissipation limits of a given component.

Two basic approaches for enhancing thermal performance are listed below:

- Improving the power dissipation capability of the PCB design
- Improving the thermal coupling of the component to the PCB

As power demand in portable designs is more and more important, designers must figure the best trade-off between efficiency, power dissipation and solution size. Due to integration and miniaturization, junction temperature can increase significantly which could lead to bad application behaviors (that is, premature thermal shutdown or worst case reduce device reliability). Junction-to-ambient thermal resistance is highly application and board-layout dependent. In applications where high maximum power dissipation exists, special care must be paid to thermal dissipation issues in board design. Keep the device operating junction temperature (T_J) below 125°C.

11 Device and Documentation Support

11.1 Device Support

11.1.1 第三方产品免责声明

TI 发布的与第三方产品或服务有关的信息，不能构成与此类产品或服务或保修的适用性有关的认可，不能构成此类产品或服务单独或与任何 TI 产品或服务一起的表示或认可。

11.1.2 Development Support

11.1.2.1 Custom Design With WEBENCH® Tools

[Click here](#) to create a custom design using the TPS61372 device with the WEBENCH® Power Designer.

1. Start by entering the input voltage (V_{IN}), output voltage (V_{OUT}), and output current (I_{OUT}) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:

- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at www.ti.com/WBENCH.

11.2 接收文档更新通知

要接收文档更新通知，请导航至 ti.com 上的器件产品文件夹。点击 [订阅更新](#) 进行注册，即可每周接收产品信息更改摘要。有关更改的详细信息，请查看任何已修订文档中包含的修订历史记录。

11.3 支持资源

TI E2E™ 支持论坛 是工程师的重要参考资料，可直接从专家获得快速、经过验证的解答和设计帮助。搜索现有解答或提出自己的问题可获得所需的快速设计帮助。

链接的内容由各个贡献者“按原样”提供。这些内容并不构成 TI 技术规范，并且不一定反映 TI 的观点；请参阅 TI 的《使用条款》。

TPS61372YKBT	Active	Production	DSBGA (YKB) 16	250 SMALL T&R	Yes	SNAGCU	Level-1-260C-UNLIM	-40 to 125	TPS 61372
TPS61372YKBT.A	Active	Production	DSBGA (YKB) 16	250 SMALL T&R	Yes	SNAGCU	Level-1-260C-UNLIM	-40 to 125	TPS 61372

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
