4 修订历史记录

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision B (December 2013) to Revision C	Page
• 已添加 ESD 额定值表，特性描述部分，器件功能模式，应用和实施部分，电源相关建议部分，布局部分，器件和文档支持部分以及机械、封装和可订购信息部分	1
• Updated conditions for <i>Electrical Characteristics</i> from $T_J = 25^{\circ}\text{C}$ to $T_J = -40^{\circ}\text{C}$ to 125°C	6
• Updated UVLO minimum for falling V_{IN} to 3.4 from 3.5	6
• Updated enable threshold rising maximum to 1.3 and falling minimum to 1.0, from 1.26 and 1.10, respectively	6

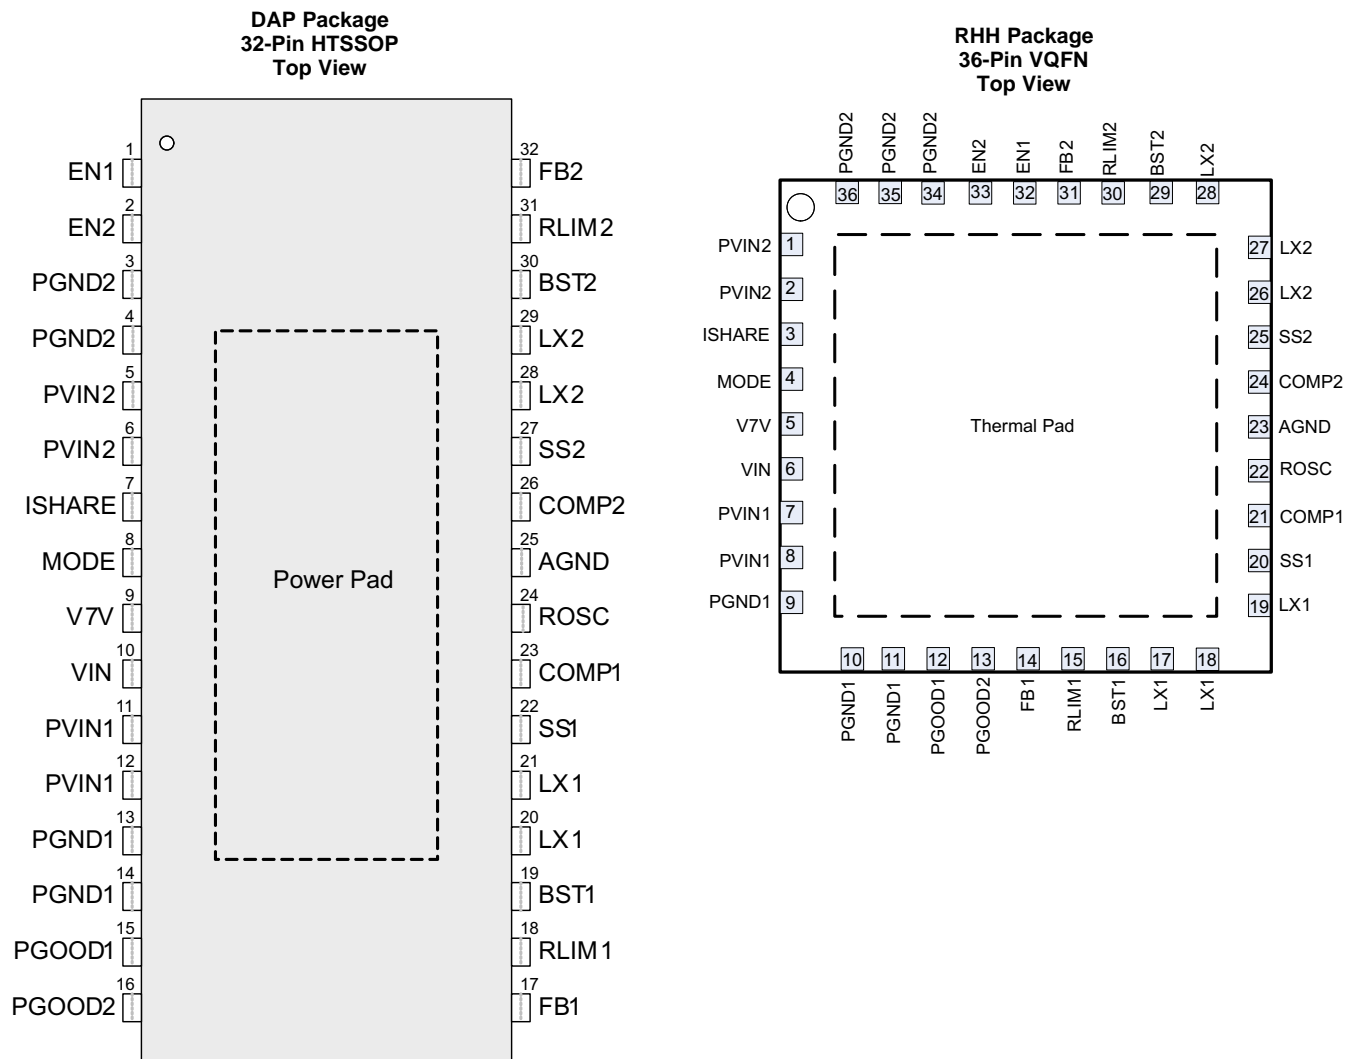

Changes from Revision A (December 2013) to Revision B	Page
• Changed I_{LIMIT2} test conditions	6
• Changed <i>Functional Block Diagram</i>	12
• Changed <i>Current Sharing Operation</i> section	15
• Changed Loop Compensation section	20

5 说明 (续)

低侧反向过流保护还能够防止过多灌电流损坏转换器。TPS65279 还特有一个由 MODE 引脚配置控制的轻负载脉冲跳跃模式 (PSM)。

TPS65279 采用 32 引脚耐热增强型 HTSSOP (DAP) 封装和 36 引脚 6mm × 6mm VQFN (RHH) 封装。

6 Pin Configuration and Functions

Pin Functions

PIN			DESCRIPTION
NAME	HTSSOP	VQFN	
EN1, EN2	1, 2	32, 33	Enable pin. Adjust the input under-voltage lockout with two resistors.
PGND2	3, 4	34, 35, 36	Power ground of buck2, place the input capacitor's ground pin as close as possible to this pin.
PVIN2	5, 6	1, 2	Power input. Input power supply to the power switches of the power converter 2.
ISHARE	7	3	Logic pin to configure current sharing mode, tie to high to parallel two buck converters, in current sharing mode, buck1 will be used; tie to low to run in separate mode.
MODE	8	4	Connecting this pin to ground, the buck converter forces a continuous current mode (CCM) operation. Connecting this pin to V7V, the buck converter automatically operates in pulse skipping mode (PSM) at light load condition to save the power.
V7V	9	5	Internal low-drop linear regulator (LDO) output to power internal driver and control circuits. Decouple this pin to power ground with a minimum 1- μ F ceramic capacitor. Output regulates to typical 6.3 V for optimal conduction on-resistances of internal power MOSFETs. In PCB design, the power ground and analog ground should have one-point common connection at the (-) terminal of V7V bypass capacitor. If VIN is lower than 6.3 V, V7V will be slightly lower than VIN.
VIN	10	6	Power supply of the internal LDO and controllers
PVIN1	11, 12	7, 8	Power input. Input power supply to the power switches of the power converter 1.
PGND1	13, 14	9, 10, 11	Power ground of buck1, place the input capacitor's ground pin as close as possible to this pin.
PGOOD1	15	12	Power Good pin for buck1, open drain output, when output is within range, output high impedance, a 100-k Ω resistor is recommended to connect to this pin.
PGOOD2	16	13	Power Good pin for buck2, open drain output, when output is within range, output high impedance, a 100-k Ω resistor is recommended to connect to this pin.
FB1	17	14	Feedback sensing pin for buck1 output voltage. Connect this pin to the resistor divider of buck1 output. The feedback reference voltage is 0.6 V \pm 1%.
RLIM1	18	15	Current limit threshold set pin for buck1, connect a resistor between this pin to GND to set the OCP.
BST1	19	16	Add a bootstrap capacitor between BST1 and LX1. The voltage on this capacitor carries the gate drive voltage for the high-side MOSFET.
LX1	20, 21	17, 18, 19	Switching node of buck1
SS1	22, 27	20, 25	Soft-start and voltage tracking in buck1. An external capacitor connected to this pin sets the internal voltage reference rise time. Since the voltage on this pin overrides the internal reference, it can be used for tracking and sequencing. In current sharing application, this pin serves as the soft-start pin.
COMP1	23	21	Error amplifier output and loop compensation pin for buck1. Connect frequency compensation to this pin; In current sharing application, this pin serves as the compensation pin.
ROSC	24	22	Oscillator frequency programmable pin. Connect an external resistor to set the switching frequency. When connected to an external clock, the internal oscillator synchronizes to the external clock.
AGND	25	23	Analog ground of the controllers
COMP2	26	24	Error amplifier output and loop compensation pin for buck2. Connect frequency compensation to this pin. In current sharing application, float this pin.
SS2	27	25	Soft-start and voltage tracking in buck2. An external capacitor connected to this pin sets the internal voltage reference rise time. Since the voltage on this pin overrides the internal reference, it can be used for tracking and power sequencing. In current sharing application, float this pin.
LX2	28, 29	26, 27, 28	Switching nodes
BST2	30	29	Add a bootstrap capacitor between BST2 and LX2. The voltage on this capacitor carries the gate drive voltage for the high-side MOSFET of buck2.
RLIM2	31	30	Current limit threshold set pin for buck2, connect a resistor between this pin to GND to set the OCP.
FB2	32	31	Feedback sensing pin for buck2 output voltage. Connect this pin to the resistor divider of buck2 output. The feedback reference voltage is 0.6 V \pm 1%. In current sharing mode, connect this pin to ground.
Exposed Thermal Pad	33	37	Exposed thermal pad of the package. Connect to the power ground. Always solder thermal pad to the board, and have as many vias as possible on the PCB to enhance power dissipation. There is no electric signal down bonded to the thermal pad inside the IC package.

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

	MIN	MAX	UNIT
Voltage at VIN, PVIN1, PVIN2	−0.3	20	V
Voltage at LX1, LX2 (maximum withstand voltage transient < 20 ns)	−4.5	23	V
Voltage at BST1, BST2, referenced to LX1, LX2 pin	−0.3	7	V
Voltage at V7V, EN1, EN2, RLIM1, RLIM2, PGOOD1, PGOOD2, MODE, ISHARE, ROSC	−0.3	7	V
Voltage at SS1, SS2, FB1, FB2, COMP1, COMP2	−0.3	3.6	V
Voltage at AGND, PGND1, PGND2	−0.3	0.3	V
T _J Operating virtual junction temperature	−40	150	°C
T _{stg} Storage temperature	−55	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

7.2 ESD Ratings

		VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM)	2000
		Charge device model (CDM)	1000

8 Detailed Description

8.1 Overview

TPS65279 is a dual 5-A/5-A output current, synchronous step-down (buck) converter with integrated N-channel MOSFETs. A wide 4.5-V to 18-V input supply range to buck encompasses most intermediate bus voltages operating off 9-V, 12-V or 15-V power bus.

TPS65279 implements a constant frequency, peak current mode control which simplifies external frequency compensation. The wide switching frequency of 200 kHz to 1600 kHz allows for efficiency and size optimization when selecting the output filter components. The switching frequency can be adjusted with an external resistor to ground on the ROSC pin. The TPS65279 also has an internal phase lock loop (PLL) controlled by the ROSC pin that can be used to synchronize the switching cycle to the falling edge of an external system clock. 180° out-of-phase operation between two channels reduces input filter and power supply induced noise.

TPS65279 has been designed for safe monotonic startup into prebiased loads. The default start up is typically 4.5 V. The EN pin has an internal pullup current source that can be used to adjust the input voltage under voltage lockout (UVLO) with two external resistors. In addition, the EN pin can be floating for automatically starting up the TPS65279 with the internal pullup current.

The integrated MOSFETs of each channel allow for high efficiency power supply designs with continuous output currents up to 5 A. The MOSFETs have been sized to optimize efficiency for lower duty cycle applications.

The TPS65279 reduces the external component count by integrating the boot recharge circuit. The bias voltage for the integrated high-side MOSFET is supplied by a capacitor between the BOOT and LX pins. The boot capacitor voltage is monitored by a BOOT to LX UVLO (BOOT-LX UVLO) circuit allowing LX pin to be pulled low to recharge the boot capacitor. The TPS65279 can operate at 100% duty cycle as long as the boot capacitor voltage is higher than the preset BOOT-LX UVLO threshold which is typically 2.1 V.

The TPS65279 has a power good comparator with hysteresis which monitors the output voltage through internal feedback voltage.

The SS (soft start/tracking) pin is used to minimize inrush current or provide power supply sequencing during power up. A small value capacitor or resistor divider should be coupled to the pin for soft start or critical power supply sequencing requirements.

The TPS65279 is protected from output overvoltage, overload, and thermal fault conditions. The TPS65279 minimizes excessive output overvoltage transients by taking advantage of the power good comparator. When the overvoltage comparator is activated, the high-side MOSFET is turned off and prevented from turning on until the internal feedback voltage is lower than 107.5% of the 0.6-V reference voltage. The TPS65279 implements both high-side MOSFET overload protection and bidirectional low-side MOSFET overload protections which help control the inductor current and avoid current runaway. If the over current condition has lasted for more than the hiccup wait time, the TPS65279 will shut down and re-start after the hiccup time. The TPS65279 also shuts down if the junction temperature is higher than thermal shutdown trip point. When the junction temperature drops 20°C typically below the thermal shutdown trip point, the built-in thermal shutdown hiccup timer is triggered. The TPS65279 will be restarted under control of the soft start circuit automatically after the thermal shutdown hiccup time is over.

Furthermore, if the over-current condition has lasted for more than the hiccup wait time which is programmed for 512 switching cycles, the TPS65279 will shut down itself and restart after the hiccup time which is set for 16384 cycles. The hiccup mode helps to reduce the device power dissipation under severe over-current conditions.

The TPS65279 operates at any load conditions unless the COMP pin voltage drops below the COMP pin start switching threshold which is typically 0.25 V.

When PSM mode operation is enabled, the TPS65279 monitors the peak switch current of the high-side MOSFET. Once the peak switch current is lower than typically 1 A, the device stops switching to boost the efficiency until the peak switch current is higher than typically 1 A again.

Feature Description (continued)

8.3.2.1 Synchronization

An internal phase locked loop (PLL) has been implemented to allow synchronization between 200 kHz and 1600 kHz, and to easily switch from Resistor mode to Synchronization mode.

To implement the synchronization feature, connect a square wave clock signal to the ROSC pin with a duty cycle between 20% to 80%. The clock signal amplitude must transition lower than 0.8 V and higher than 2 V. The start of the switching cycle is synchronized to the falling edge of ROSC pin.

In applications where both Resistor mode and Synchronization mode are needed, the device can be configured as shown in Figure 17. Before the external clock is present, the device works in Resistor mode and the switching frequency is set by ROSC resistor. When the external clock is present, the Synchronization mode overrides the Resistor mode. The first time the ROSC pin is pulled above the ROSC high threshold (2 V), the device switches from the Resistor mode to the Synchronization mode and the ROSC pin becomes high impedance as the PLL starts to lock onto the frequency of the external clock. It is not recommended to switch from the Synchronization mode back to the Resistor mode because the internal switching frequency drops to 100 kHz first before returning to the switching frequency set by ROSC resistor.

Figure 17. Resistor Mode and Synchronization Mode

8.3.3 Soft-Start Time

The start-up of buck output is controlled by the voltage on the respective SS pin. When the voltage on the SS pin is less than the internal 0.6-V reference, the TPS65279 regulates the internal feedback voltage to the voltage on the SS pin instead of 0.6 V. The SS pin can be used to program an external soft-start function or to allow output of buck to track another supply during start-up. The device has an internal pullup current source of 6 μ A that charges an external soft-start capacitor to provide a linear ramping voltage at SS pin. The TPS65279 regulates the internal feedback voltage according to the voltage on the SS pin, allowing VOUT to rise smoothly from 0 V to its final regulated voltage. The total soft-start time will be calculated approximately:

$$t_{SS}(\text{ms}) = C_{SS}(\text{nF}) \times \left(\frac{0.6 \text{ V}}{6 \mu\text{A}} \right) \quad (1)$$

8.3.4 Out-of-Phase Operation

In order to reduce input ripple current, Buck 1 and Buck 2 operate 180° out-of-phase. This enables the system having less input ripple, then to lower component cost, save board space and reduce EMI.

8.3.5 Output Overvoltage Protection (OVP)

The device incorporates an output overvoltage protection (OVP) circuit to minimize output voltage overshoot. For example, when the power supply output is overloaded the error amplifier compares the actual output voltage to the internal reference voltage. If the FB pin voltage is lower than the internal reference voltage for a considerable time, the output of the error amplifier demands maximum output current. Once the condition is removed, the regulator output rises and the error amplifier output transitions to the steady state voltage. In some applications

Feature Description (continued)

with small output capacitance, the power supply output voltage can respond faster than the error amplifier. This leads to the possibility of an output overshoot. The OVP feature minimizes the overshoot by comparing the FB pin voltage to the OVP threshold. If the FB pin voltage is greater than the OVP threshold the high-side MOSFET is turned off preventing current from flowing to the output and minimizing output overshoot. When the FB voltage drops lower than the OVP threshold, the high-side MOSFET is allowed to turn on at the next clock cycle.

8.3.6 Bootstrap Voltage (BOOT) and Low Dropout Operation

The device has an integrated boot regulator, and requires a small ceramic capacitor between the BOOT and LX pins to provide the gate drive voltage for the high-side MOSFET. The boot capacitor is charged when the BOOT pin voltage is less than VIN and BOOT-LX voltage is below regulation. The value of this ceramic capacitor should be 0.1 μ F. A ceramic capacitor with an X7R or X5R grade dielectric with a voltage rating of 10 V or higher is recommended because of the stable characteristics over temperature and voltage.

To improve drop out, the device is designed to operate at 100% duty cycle as long as the BOOT to LX pin voltage is greater than the BOOT-LX UVLO threshold which is typically 2.1 V. When the voltage between BOOT and LX drops below the BOOT-LX UVLO threshold the high-side MOSFET is turned off and the low-side MOSFET is turned on allowing the boot capacitor to be recharged. In applications with split input voltage rails, 100% duty cycle operation can be achieved as long as $(V_{IN} - P_{VIN}) > 4$ V.

8.3.7 Overcurrent Protection

The device is protected from over current conditions by cycle-by-cycle current limiting on both the high-side MOSFET and the low-side MOSFET.

8.3.7.1 High-Side MOSFET Overcurrent Protection

The device implements current mode control which uses the COMP pin voltage to control the turn off of the high-side MOSFET and the turn on of the low-side MOSFET on a cycle by cycle basis. Each cycle the switch current and the current reference generated by the COMP pin voltage are compared, when the peak switch current intersects the current reference the high-side switch is turned off.

TPS65279 features adjustable overcurrent protection trip point. The peak current limit can be set by external resistors connected between pin RLIM1/2 to ground. By setting lower current limit, lower current rating inductor can be used to reduce system cost.

Figure 18. Peak Current Limit vs R_{LIMIT}

$$I_{lim} (A) = 168.98 \times R_{LIMIT} (k\Omega)^{-0.763} \quad (2)$$

Feature Description (continued)

8.3.7.2 Low-Side MOSFET Overcurrent Protection

While the low-side MOSFET is turned on its conduction current is monitored by the internal circuitry. During normal operation the low-side MOSFET sources current to the load. At the end of every clock cycle, the low-side MOSFET sourcing current is compared to the internally set low-side sourcing current limit. If the low-side sourcing current is exceeded, the high-side MOSFET is not turned on and the low-side MOSFET stays on for the next cycle. The high-side MOSFET is turned on again when the low-side current is below the low-side sourcing current limit at the start of a cycle.

The low-side MOSFET may also sink current from the load. If the low-side sinking current limit is exceeded the low-side MOSFET is turned off immediately for the rest of that clock cycle. In this scenario both MOSFETs are off until the start of the next cycle.

Furthermore, if an output overload condition (as measured by the COMP pin voltage) has lasted for more than the hiccup wait time which is programmed for 512 switching cycles, the device will shut down itself and restart after the hiccup time of 16384 cycles. The hiccup mode helps to reduce the device power dissipation under severe overcurrent conditions. When one channel is in OCP, the other channel is not impacted and remains independent.

8.3.8 Current Sharing Operation

As TPS65279 uses peak current mode control method, the two buck converters can be paralleled together to provide large current. Paralleling two bucks provides some advantages over single buck operation, such as smaller input and output ripple, faster response in load transient, and so forth. The converters will work in current sharing mode by connecting the iShare pin to high. Once in current mode, signal pins in Buck 2 are not active, for example, FB2, COMP2, SS2, these pins will be neglected. Connecting FB2 to GND and floating COMP2, SS2, PGOOD2 are recommended.

8.3.9 Thermal Shutdown

The internal thermal shutdown circuitry forces the device to stop switching if the junction temperature exceeds 160°C typically. Once the junction temperature drops below 140°C typically, the internal thermal hiccup timer will start to count. The device reinitiates the power up sequence after the built-in thermal shutdown hiccup time (16384 cycles) is over.

8.4 Device Functional Modes

8.4.1 CCM Operation Mode

When the VIN/PVINx are above UVLO threshold and ENx are above the threshold, two switchers operate in continuous current mode (CCM) when MODE pin connects to GND. In CCM, the converters work in peak current mode for easy loop compensation and cycle-by-cycle high side MOSFET current limit.

8.4.2 PSM Operation Mode

When connect MODE pin to V7V, PSM mode is enabled. The devices are designed to operate in high-efficiency PSM under light load conditions. Pulse skipping is initiated when the switch current falls to 0 A. During pulse skipping, the low-side FET is turned off when the switch current falls to 0 A. The switching node (LX) waveform takes on the characteristics of DCM operation and the apparent switching frequency decreases.

8.4.3 Current Sharing Mode

When ISHARE pin connects to high, SW1/SW2 pair output are shared, the responding pairs current sharing mode is enabled and the two buck converters are paralleled together to provide large current. For the detail configuration, see current sharing application schematics.

9 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The devices are step-down DC-DC converters. They are typically used to convert a higher dc voltage to a lower dc voltage with a maximum available output current of 5/5 A. The following design procedure can be used to select component values for the TPS65279. Alternately, the WEBENCH® software may be used to generate a complete design. The WEBENCH software uses an iterative design procedure and accesses a comprehensive database of components when generating a design. This section presents a simplified discussion of the design process.

9.2 Typical Applications

9.2.1 Dual Buck Operation Mode Application

Figure 19. Dual Mode Operation to Deliver 5 A at Buck1 and 5 A at Buck2

Typical Applications (continued)

9.2.1.1 Design Requirements

For this design example, use the following in [Table 1](#) as the input parameters.

Table 1. Design Parameters

PARAMETER	EXAMPLE VALUE
Input voltage range	4.5 to 18 V
Output voltage	1.2 V/1.8 V
Transient response, 1.5-A load step	$\Delta V_{out} = \pm 5\%$
Input ripple voltage	400 mV
Output ripple voltage	30 mV
Output current rating	5 A
Operating frequency	600 kHz

9.2.1.2 Detailed Design Procedure

9.2.1.2.1 Adjusting the Output Voltage

The output voltage is set with a resistor divider from the output node (VOUT) to the FB pin. TI recommends to use 1% tolerance or better divider resistors.

Figure 20. Voltage Divider Circuit

$$R2 = R1 \times \left(\frac{0.6 \text{ V}}{V_{OUT} - 0.6 \text{ V}} \right) \quad (3)$$

Start with a 40.2-k Ω for R1 and use [Equation 3](#) to calculate R2. To improve efficiency at light loads consider using larger value resistors. If the values are too high, the regulator is more susceptible to noise and voltage errors from the FB input current are noticeable.

The minimum output voltage and maximum output voltage can be limited by the minimum on time of the high-side MOSFET and bootstrap voltage (BOOT-LX voltage) respectively. See [Bootstrap Voltage \(BOOT\) and Low Dropout Operation](#) for more information.

9.2.1.2.2 Adjusting UVLO

If an application requires either a higher UVLO threshold on the VIN pin or a secondary UVLO on the PVIN, in split rail applications, then the EN pin can be configured as shown in [Figure 21](#).

When using the external UVLO function, TI recommends to set the hysteresis to >500 mV.

The EN pin has a small pullup current I_P which sets the default state of the pin to enable when no external components are connected. The pullup current is also used to control the voltage hysteresis for the UVLO function since it increases by I_h once the EN pin crosses the enable threshold. The UVLO thresholds can be calculated using [Equation 4](#) and [Equation 5](#).

Figure 21. Adjustable VIN UVLO

$$R_1 = \frac{V_{START} \left(\frac{V_{ENFALLING}}{V_{ENRISING}} \right) - V_{STOP}}{I_P \left(1 - \frac{V_{ENFALLING}}{V_{ENRISING}} \right) + I_h} \quad (4)$$

$$R_2 = \frac{R_1 \times V_{ENFALLING}}{V_{STOP} - V_{ENFALLING} + R_1(I_h + I_P)}$$

where

- $I_h = 3 \mu A$
- $I_P = 3 \mu A$
- $V_{ENRISING} = 1.21 V$
- $V_{ENFALLING} = 1.17 V$

(5)

9.2.1.2.3 Adjustable Switching Frequency (Resistor Mode)

To determine the ROSC resistance for a given switching frequency, use [Equation 6](#) or the curve in [Figure 22](#). To reduce the solution size one would set the switching frequency as high as possible, but tradeoffs of the supply efficiency and minimum controllable on time should be considered.

Figure 22. ROSC vs Switching Frequency

$$R_{osc}(k\Omega) = 45580 \times f_{sw}^{-1.019} (kHz) \quad (6)$$

9.2.1.2.4 Output Inductor Selection

To calculate the value of the output inductor, use [Equation 7](#). LIR is a coefficient that represents the amount of inductor ripple current relative to the maximum output current. The inductor ripple current is filtered by the output capacitor. Therefore, choosing high inductor ripple currents impact the selection of the output capacitor since the output capacitor must have a ripple current rating equal to or greater than the inductor ripple current. In general, the inductor ripple value is at the discretion of the designer; however, LIR is normally from 0.1 to 0.3 for the majority of applications.

$$L = \frac{V_{inmax} - V_{out}}{I_o \times LIR} \times \frac{V_{out}}{V_{inmax} \times f_{sw}} \quad (7)$$

For the output filter inductor, it is important that the RMS current and saturation current ratings not be exceeded. The RMS and peak inductor current can be found from [Equation 9](#) and [Equation 10](#).

$$I_{ripple} = \frac{V_{inmax} - V_{out}}{L} \times \frac{V_{out}}{V_{inmax} \times f_{sw}} \quad (8)$$

$$I_{Lrms} = \sqrt{I_o^2 + \frac{\left(\frac{V_{out} \times (V_{inmax} - V_{out})}{V_{inmax} \times L \times f_{sw}} \right)^2}{12}} \quad (9)$$

$$I_{Lpeak} = I_o + \frac{I_{ripple}}{2} \quad (10)$$

The current flowing through the inductor is the inductor ripple current plus the output current. During power up, faults or transient load conditions, the inductor current can increase above the calculated peak inductor current level calculated above. In transient conditions, the inductor current can increase up to the switch current limit of the device. For this reason, the most conservative approach is to specify an inductor with a saturation current rating equal to or greater than the switch current limit rather than the peak inductor current.

9.2.1.2.5 Output Capacitor Selection

There are three primary considerations for selecting the value of the output capacitor. The output capacitor determines the modulator pole, the output voltage ripple, and how the regulator responds to a large change in load current. The output capacitance needs to be selected based on the most stringent of these three criteria.

The desired response to a large change in the load current is the first criteria. The output capacitor needs to supply the load with current when the regulator cannot. This situation would occur if there are desired hold-up times for the regulator where the output capacitor must hold the output voltage above a certain level for a specified amount of time after the input power is removed. The regulator is also temporarily not able to supply sufficient output current if there is a large, fast increase in the current needs of the load such as a transition from no load to full load. The regulator usually needs two or more clock cycles for the control loop to see the change in load current and output voltage and adjust the duty cycle to react to the change. The output capacitor must be sized to supply the extra current to the load until the control loop responds to the load change. The output capacitance must be large enough to supply the difference in current for 2 clock cycles while only allowing a tolerable amount of droop in the output voltage. [Equation 11](#) shows the minimum output capacitance necessary to accomplish this.

$$C_o = \frac{2 \times \Delta I_{out}}{f_{sw} \times \Delta V_{out}}$$

where

- ΔI_{OUT} is the change in output current.
 - f_{sw} is the regulators switching frequency.
 - ΔV_{OUT} is the allowable change in the output voltage.
- (11)

For this example, the transient load response is specified as a 5% change in V_{OUT} for a load step of 3 A. For this example, $\Delta I_{OUT} = 3$ A and $\Delta V_{OUT} = 0.05 \times 3.3 = 0.165$ V. Using these numbers gives a minimum capacitance of 75.8 μ F. This value does not take the ESR of the output capacitor into account in the output voltage change. For ceramic capacitors, the ESR is usually small enough to ignore in this calculation.

Equation 12 calculates the minimum output capacitance needed to meet the output voltage ripple specification.

$$C_o > \frac{1}{8 \times f_{sw}} \times \frac{1}{\frac{V_{oripple}}{I_{oripple}}}$$

where

- f_{sw} is the switching frequency.
- $V_{oripple}$ is the maximum allowable output voltage ripple.
- $I_{oripple}$ is the inductor ripple current.

(12)

Equation 13 calculates the maximum ESR an output capacitor can have to meet the output voltage ripple specification.

$$R_{esr} < \frac{V_{oripple}}{I_{oripple}} \quad (13)$$

Additional capacitance deratings for aging, temperature, and DC bias should be factored in which increases this minimum value.

Capacitors generally have limits to the amount of ripple current they can handle without failing or producing excess heat. An output capacitor that can support the inductor ripple current must be specified. Some capacitor data sheets specify the root mean square (RMS) value of the maximum ripple current. **Equation 14** can be used to calculate the RMS ripple current the output capacitor needs to support.

$$I_{corms} = \frac{V_{out} \times (V_{inmax} - V_{out})}{\sqrt{12} \times V_{inmax} \times L \times f_{sw}} \quad (14)$$

9.2.1.2.6 Input Capacitor Selection

The TPS65279 requires a high-quality ceramic, type X5R or X7R, input decoupling capacitor of at least 10-μF of effective capacitance on the PVIN input voltage pins. In some applications additional bulk capacitance may also be required for the PVIN input. The effective capacitance includes any DC bias effects. The voltage rating of the input capacitor must be greater than the maximum input voltage. The capacitor must also have a ripple current rating greater than the maximum input current ripple of the TPS65279. The input ripple current can be calculated using **Equation 15**.

$$I_{inrms} = I_{out} \times \sqrt{\frac{V_{out}}{V_{inmin}} \times \frac{(V_{inmin} - V_{out})}{V_{inmin}}} \quad (15)$$

The value of a ceramic capacitor varies significantly over temperature and the amount of DC bias applied to the capacitor. The capacitance variations due to temperature can be minimized by selecting a dielectric material that is stable over temperature. X5R and X7R ceramic dielectrics are usually selected for power regulator capacitors because they have a high capacitance to volume ratio and are fairly stable over temperature. The output capacitor must also be selected with the DC bias taken into account. The capacitance value of a capacitor decreases as the DC bias across a capacitor increases. For this example design, a ceramic capacitor with at least a 25-V voltage rating is required to support the maximum input voltage. TPS65279 may operate from a single supply. The input capacitance value determines the input ripple voltage of the regulator. The input voltage ripple can be calculated using **Equation 16**.

$$\Delta V_{in} = \frac{I_{outmax} \times 0.25}{C_{in} \times f_{sw}} \quad (16)$$

9.2.1.2.7 Loop Compensation

Integrated buck DC/DC converter in TPS65279 incorporates a peak current mode control scheme. The error amplifier is a transconductance amplifier with a gain of 1350 μA/V. A typical type II compensation circuit adequately delivers a phase margin between 60° and 90°. C_b adds a high frequency pole to attenuate high frequency noise when needed. To calculate the external compensation components, follow the following steps.

1. Select switching frequency f_{sw} that is appropriate for application depending on L and C sizes, output ripple, EMI, and etc. Switching frequency between 500 kHz to 1 MHz gives best trade off between performance and cost. To optimize efficiency, lower switching frequency is desired.

2. Set up cross over frequency, f_c , which is typically between $1/5$ and $1/20$ of f_{sw} .
3. R_C can be determined by:

$$R_C = \frac{2\pi \times f_c \times V_O \times C_O}{g_M \times V_{ref} \times g_{mps}}$$

where

- g_M is the error amplifier gain (1350 $\mu A/V$).
- g_{mps} is the power stage voltage to current conversion gain (10 A/V).

4. Calculate C_C by placing a compensation zero at or before the dominant pole:

$$(f_P = \frac{1}{C_O \times R_L \times 2\pi}) \quad (17)$$

$$C_C = \frac{R_L \times C_O}{R_C} \quad (18)$$

5. Optional C_b can be used to cancel the zero from the ESR associated with C_O .

$$C_b = \frac{R_{ESR} \times C_O}{R_C} \quad (19)$$

9.2.2 Current Sharing Mode Operation Application

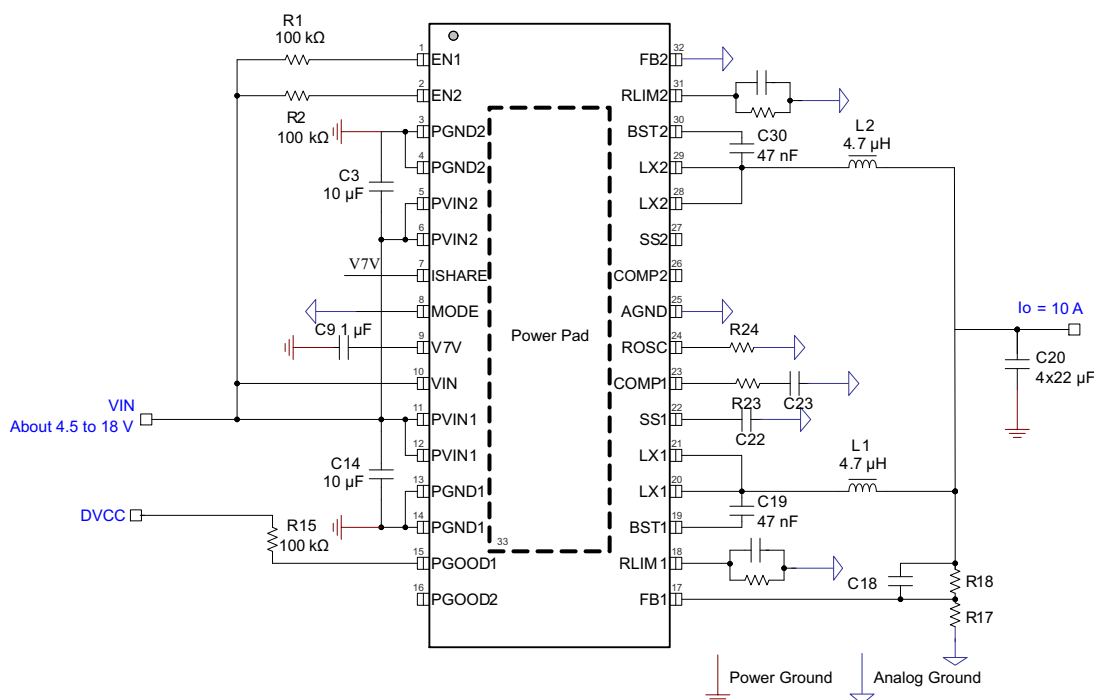

Figure 37. Share Mode Operation to Deliver 10 A

9.2.2.1 Design Requirements

See previous [Design Requirements](#).

9.2.2.2 Detailed Design Procedure

As TPS65279 utilizes peak current mode control method, the two buck converters can be paralleled together to provide large current. The converters will work in current sharing mode by connecting the iShare pin to high. Once in current mode, signal pins in Buck 2 are not active, for example, FB2, COMP2, SS2, these pins will be neglected. Connecting FB2 to GND and floating COMP2, SS2, PGOOD2 are recommended.

For other component selection, refer to previous [Detailed Design Procedure](#).

10 Power Supply Recommendations

This device is designed to operate from an input voltage supply range between 4.5 and 18 V. This input power supply should be well regulated. If the input supply is located more than a few inches from the TPS65400 converter, additional bulk capacitance may be required in addition to the ceramic bypass capacitors. An electrolytic capacitor with a value of 22 μ F is a typical choice.

11 Layout

11.1 Layout Guidelines

The designer can layout the TPS65279 on a 2-layer PCB as shown in Figure 46.

Layout is a critical portion of good power supply design. See Figure 46 for a PCB layout example. The top layer contains the main power traces for VIN, VOUT, and VLX. Also on the top layer are connections for the remaining pins of the TPS65279 and a large top side area filled with ground. The top layer ground area should be connected to the internal ground layer(s) using vias at the input bypass capacitor, the output filter capacitor and directly under the TPS65279 device to provide a thermal path from the exposed thermal pad land to ground. The bottom layer acts as ground plane connecting analog ground and power ground.

The GND pin should be tied directly to the power pad under the IC and the power pad. For operation at full rated load, the top side ground area together with the internal ground plane, must provide adequate heat dissipating area. There are several signals paths that conduct fast changing currents or voltages that can interact with stray inductance or parasitic capacitance to generate noise or degrade the power supplies performance. To help eliminate these problems, the PVIN pin should be bypassed to ground with a low ESR ceramic bypass capacitor with X5R or X7R dielectric. Take care to minimize the loop area formed by the bypass capacitor connections, the PVIN pins, and the ground connections.

The VIN pin must also be bypassed to ground using a low ESR ceramic capacitor with X5R or X7R dielectric.

Since the LX connection is the switching node, the output inductor should be located close to the LX pins, and the area of the PCB conductor minimized to prevent excessive capacitive coupling. The output filter capacitor ground should use the same power ground trace as the PVIN input bypass capacitor. Try to minimize this conductor length while maintaining adequate width. The additional external components can be placed approximately as shown.

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature numbers SLMA002 (www.ti.com/lit/slma002) and SLMA004 (www.ti.com/lit/slma004).
9. Size of metal pad may vary due to creepage requirement.

EXAMPLE STENCIL DESIGN

DAP0032D

PowerPAD™ TSSOP - 1.2 mm max height

PLASTIC SMALL OUTLINE

SOLDER PASTE EXAMPLE
EXPOSED PAD
100% PRINTED SOLDER COVERAGE BY AREA
SCALE:8X

STENCIL THICKNESS	SOLDER STENCIL OPENING
0.1	2.80 X 4.68
0.125	2.50 X 4.19 (SHOWN)
0.15	2.28 X 3.83
0.175	2.11 X 3.54

4231420/A 07/2025

NOTES: (continued)

10. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
11. Board assembly site may have different recommendations for stencil design.

重要通知和免责声明

TI“按原样”提供技术和可靠性数据（包括数据表）、设计资源（包括参考设计）、应用或其他设计建议、网络工具、安全信息和其他资源，不保证没有瑕疵且不做任何明示或暗示的担保，包括但不限于对适销性、某特定用途方面的适用性或不侵犯任何第三方知识产权的暗示担保。

这些资源可供使用 TI 产品进行设计的熟练开发人员使用。您将自行承担以下全部责任：(1) 针对您的应用选择合适的 TI 产品，(2) 设计、验证并测试您的应用，(3) 确保您的应用满足相应标准以及任何其他功能安全、信息安全、监管或其他要求。
