

# ADS891xB 18ビット、リファレンス・バッファ内蔵、 拡張性能機能搭載、高速SAR ADC

## 1 特長

- 分解能: 18ビット
- 高いサンプリング・レートとレイテンシなしの出力
  - ADS8910B: 1MSPS
  - ADS8912B: 500kSPS
  - ADS8914B: 250kSPS
- LDO搭載により単一電源で動作可能
- 低消費電力でドループなしのリファレンス・バッファ
- 非常に優れたACおよびDC性能
  - SNR: 102.5dB, THD: -125dB
  - INL:  $\pm 0.5$  LSB
  - DNL:  $\pm 0.2$  LSB, 18ビット、ノー・ミッシング・コード
- 広い入力電圧範囲
  - ユニポーラ差動入力電圧範囲:  $\pm V_{REF}$
  - $V_{REF}$ 入力電圧範囲: 2.5V~5V
- 単一電源、低消費電力の動作  
(内部リファレンス・バッファおよびLDOを含む)
  - ADS8910B: 1MSPSで21mW
  - ADS8912B: 500kSPSで16mW
  - ADS8914B: 250kSPSで14mW
- 拡張SPIデジタル・インターフェイス
  - インターフェイスSCLK: 1MSPSで20MHz
  - 構成可能なデータ・パリティ出力
- 拡張温度範囲:  $-40^{\circ}\text{C}$ ~ $+125^{\circ}\text{C}$
- 小さな占有面積: 4mm $\times$ 4mm VQFN

## 2 アプリケーション

- 試験/測定機器
- 医療用画像処理
- 高精度、高速のデータ収集

## 3 概要

ADS8910B、ADS8912B、ADS8914B (ADS891xB)は、ピン互換の高速、シングル・チャンネル、高精度の18ビット逐次比較型(SAR)アナログ/デジタル・コンバータ(ADC)ファミリに属し、リファレンス・バッファと低ドロップアウト・レギュレータ(LDO)が搭載されています。このデバイス・ファミリには、ADS890xB (20ビット)およびADS892xB (16ビット)の分解能バリエーションが含まれます。

ADS891xBはTIの拡張SPI機能を使用し、アナログ性能の向上とともに、データ転送の高い分解能を維持します。ADS89xxBは、拡張SPIにより低いクロック速度で高いスループットを達成できるため、基板のレイアウトを簡素化し、システムのコストを低減できます。また、拡張SPIによってデータのクロックインも簡素化されるため、このデバイスはFPGAやDSPに関わるアプリケーションに理想的です。ADS89xxBは、標準のSPIインターフェイスと互換性があります。

ADS891xBには内部データ・パリティ機能があり、ADCデータ出力にパリティを追加できます。パリティ・ビットを使用してホストでADCデータを検証することにより、システムの信頼性が向上します。

### SPIインターフェイスのクロック: 1MSPS

| デバイスの分解能 | 3線式SPI | 3線式拡張SPI |
|----------|--------|----------|
| 20ビット    | 70MHz  | 22MHz    |
| 18ビット    | 58MHz  | 20MHz    |
| 16ビット    | 52MHz  | 18MHz    |

- (1) 拡張SPIのすべての機能については、「[インターフェイス・モジュール](#)」セクションを参照してください。

### ADS89xxB内蔵の機能によりシステムを簡単に設計

Multi-ADC System With Single Supply and Reference

Lowest Clock Speeds at 1-MSPS Using 3-Wire Enhanced-SPI

## 4 改訂履歴

資料番号末尾の英字は改訂を表しています。その改訂履歴は英語版に準じています。

| Revision A (July 2016) から Revision B に変更                                                                                                                      | Page |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| • 表紙の図 変更 .....                                                                                                                                               | 1    |
| • Changed REFBUFOUT pin description from "Reference buffer output, ADC reference input" to "Internal reference buffer output, external reference input" ..... | 4    |
| • Changed DV <sub>DD</sub> range in condition line of Electrical Characteristics from 2.35 V to 3.6 V to 1.65 V to 5.5 V .....                                | 7    |
| • Changed maximum value for DV <sub>DD</sub> range in specifications tables from 3.6 V to 5.5 V .....                                                         | 7    |
| • Added T <sub>A</sub> = 25°C to reference buffer offset voltage test condition in <i>Electrical Characteristics</i> table .....                              | 7    |
| • Changed input offset thermal drift typ value from 10 to 1 .....                                                                                             | 7    |
| • Added 100-kHz condition to SNR and THD parameters in the Electrical Characteristics .....                                                                   | 8    |
| • Added f <sub>IN</sub> = 2 kHz test condition to SFDR in <i>Electrical Characteristics</i> table .....                                                       | 8    |
| • Added new conditions to serial clock frequency in the <i>Timing Requirements</i> table .....                                                                | 9    |
| • Added serial clock frequency conditions in <i>Timing Characteristics</i> table .....                                                                        | 9    |
| • Added strobe output time to <i>Switching Characteristics</i> table .....                                                                                    | 10   |
| • Added Figure 26, <i>Noise Performance vs Input Frequency</i> .....                                                                                          | 16   |
| • Added Figure 27, <i>Distortion Performance vs Input Frequency</i> .....                                                                                     | 16   |
| • Added descriptive text and one figure to the <i>Reference Buffer Module</i> section .....                                                                   | 19   |
| • Changed t <sub>d_RVS</sub> to t <sub>d_CSRDY</sub> in step 3 of <i>Data Transfer Frame</i> section .....                                                    | 31   |
| • Deleted text from first note element regarding data transfer activity in zone 2 .....                                                                       | 34   |
| • Added new note (1) for SCLK in Table 9 .....                                                                                                                | 44   |
| • Changed <i>Data Acquisition (DAQ) Circuit for Lowest Distortion and Noise Performance...</i> section for clarity .....                                      | 59   |
| • Added more design parameters to <i>Design Parameters</i> table .....                                                                                        | 59   |
| • Changed <i>Detailed Design Procedure</i> section for clarity .....                                                                                          | 60   |
| • Added two new application curves .....                                                                                                                      | 60   |
| • Added new typical application subsection .....                                                                                                              | 61   |
| • Added text to <i>Power-Supply Recommendations</i> section for clarity .....                                                                                 | 64   |

| NC                      | 6      | No connection       | Float these pins; no external connection.                                                                                                                                                                                 |
| REFBUFOUT               | 5, 7   | Analog input/output | Internal reference buffer output, external reference input. Short pin 5 and 7 together.                                                                                                                                   |
| REFIN                   | 3      | Analog input        | Reference voltage input                                                                                                                                                                                                   |
| REFM                    | 4, 8   | Analog input        | Reference ground potential                                                                                                                                                                                                |
| $\overline{\text{RST}}$ | 2      | Digital input       | Asynchronous reset input pin.<br>A low pulse on the $\overline{\text{RST}}$ pin resets the device. All register bits return to the default state.                                                                         |
| RVDD                    | 12     | Power supply        | Analog power supply pin.                                                                                                                                                                                                  |
| RVS                     | 21     | Digital output      | Multifunction output pin.<br>With $\overline{\text{CS}}$ held high, RVS reflects the status of the internal ADCST signal.<br>With $\overline{\text{CS}}$ low, the status of RVS depends on the output protocol selection. |
| SCLK                    | 23     | Digital input       | Clock input pin for the serial interface.<br>All system-synchronous data transfer protocols are timed with respect to the SCLK signal.                                                                                    |
| SDI                     | 22     | Digital input       | Serial data input pin.<br>This pin is used to feed data or commands into the device.                                                                                                                                      |

### Pin Functions (continued)

| PIN         |     | FUNCTION       | DESCRIPTION                             |
|-------------|-----|----------------|-----------------------------------------|
| NAME        | NO. |                |                                         |
| SDO-0       | 20  | Digital output | Serial communication pin: data output 0 |
| SDO-1       | 19  | Digital output | Serial communication pin: data output 1 |
| SDO-2       | 18  | Digital output | Serial communication pin: data output 2 |
| SDO-3       | 17  | Digital output | Serial communication pin: data output 3 |
| Thermal pad |     | Supply         | Exposed thermal pad; connect to GND.    |

## 6 Specifications

### 6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)<sup>(1)</sup>

|                                                                                              | MIN  | MAX        | UNIT |
|----------------------------------------------------------------------------------------------|------|------------|------|
| RVDD to GND                                                                                  | –0.3 | 7          | V    |
| DVDD to GND                                                                                  | –0.3 | 7          | V    |
| REFIN to REFM                                                                                | –0.3 | RVDD + 0.3 | V    |
| REFM to GND                                                                                  | –0.1 | 0.1        | V    |
| Analog Input (AINP, AINM) to GND                                                             | –0.3 | VREF + 0.3 | V    |
| Digital input ( $\overline{\text{RST}}$ , CONVST, $\overline{\text{CS}}$ , SCLK, SDI) to GND | –0.3 | DVDD + 0.3 | V    |
| Digital output (RVS, SDO-0, SDO-1, SDO-2, SDO-3) to GND                                      | –0.3 | DVDD + 0.3 | V    |
| Analog Input (AINP, AINM) to RVDD and GND                                                    | –130 | 130        | mA   |
| Operating free-air temperature, T <sub>A</sub>                                               | –40  | 125        | °C   |
| Storage temperature, T <sub>stg</sub>                                                        | –65  | 150        | °C   |

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

### 6.2 ESD Ratings

|                                            | VALUE                                                                          | UNIT  |
|--------------------------------------------|--------------------------------------------------------------------------------|-------|
| V <sub>(ESD)</sub> Electrostatic discharge | Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>              | ±2000 |
|                                            | Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup> | ±500  |

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.  
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

|                                                         | MIN                  | NOM        | MAX | UNIT |
|---------------------------------------------------------|----------------------|------------|-----|------|
| RVDD Analog supply voltage (RVDD to AGND)               | 3                    | 5          | 5.5 | V    |
| DVDD Digital supply voltage (DVDD to AGND)              | Operating            | 1.65       | 3   | 5.5  |
|                                                         | Specified throughput | 2.35       | 3   | 5.5  |
| VREF Reference input voltage on REFIN                   | 2.5                  | RVDD – 0.3 |     | V    |
| CREFBUF External ceramic decoupling capacitor           | 10                   | 22         |     | μF   |
| R <sub>ESR</sub> External series resistor               | 0                    | 1          | 1.3 | Ω    |
| T <sub>A</sub> Specified free-air operating temperature | –40                  | 25         | 125 | °C   |

### 6.4 Thermal Information

| THERMAL METRIC <sup>(1)</sup> |                                              | ADS891xB   | UNITS |
|-------------------------------|----------------------------------------------|------------|-------|
|                               |                                              | RGE (VQFN) |       |
|                               |                                              | 24 PINS    |       |
| R <sub>θJA</sub>              | Junction-to-ambient thermal resistance       | 31.9       | °C/W  |
| R <sub>θJC(top)</sub>         | Junction-to-case (top) thermal resistance    | 29.9       | °C/W  |
| R <sub>θJB</sub>              | Junction-to-board thermal resistance         | 8.9        | °C/W  |
| ψ <sub>JT</sub>               | Junction-to-top characterization parameter   | 0.3        | °C/W  |
| ψ <sub>JB</sub>               | Junction-to-board characterization parameter | 8.9        | °C/W  |
| R <sub>θJC(bot)</sub>         | Junction-to-case (bottom) thermal resistance | 2.0        | °C/W  |

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

## 6.5 Electrical Characteristics

At  $V_{DD} = 5.5\text{ V}$ ,  $DV_{DD} = 1.65\text{ V}$  to  $5.5\text{ V}$ ,  $V_{REF} = 5\text{ V}$ , and maximum throughput (unless otherwise noted). Minimum and maximum values at  $T_A = -40^\circ\text{C}$  to  $+125^\circ\text{C}$ ; typical values at  $T_A = 25^\circ\text{C}$ .

| PARAMETER                                                                        |                                                                              | TEST CONDITIONS                                                         | MIN                          | TYP                  | MAX                          | UNIT               |
|----------------------------------------------------------------------------------|------------------------------------------------------------------------------|-------------------------------------------------------------------------|------------------------------|----------------------|------------------------------|--------------------|

(1) See the [REF\\_MRG Register](#).

(2) For selected  $V_{REF}$ , see the [OFST\\_CAL Register](#).

(3) While operating with internal reference buffer and LDO.

(4) See [Figure 8](#), [Figure 9](#), [Figure 14](#), and [Figure 15](#) for statistical distribution data for DNL, INL, offset, and gain error parameters.

(5) LSB = least-significant bit. 1 LSB at 18-bit resolution is approximately 3.8 ppm.

(6) Includes internal reference buffer errors and drifts.

## Electrical Characteristics (continued)

At  $R_{V_{DD}} = 5.5\text{ V}$ ,  $DV_{DD} = 1.65\text{ V}$  to  $5.5\text{ V}$ ,  $V_{REF} = 5\text{ V}$ , and maximum throughput (unless otherwise noted).  
Minimum and maximum values at  $T_A = -40^\circ\text{C}$  to  $+125^\circ\text{C}$ ; typical values at  $T_A = 25^\circ\text{C}$ .

## 7 Detailed Description

### 7.1 Overview

The ADS891xB is a family of high-speed, successive approximation register (SAR), analog-to-digital converters (ADC) based on a charge redistribution architecture. These compact devices integrate a reference buffer and LDO, and feature high performance at a high throughput rate with low power consumption.

This device family supports unipolar, fully differential, analog input signals. The integrated reference buffer supports the burst mode of data acquisition for external reference voltages in the range 2.5 V to 5 V, and offers a wide selection of input ranges without additional input scaling.

When a conversion is initiated, the differential input between the AINP and AINM pins is sampled on the internal capacitor array. The device uses an internal clock to perform conversions. During the conversion process, both analog inputs are disconnected from the internal circuit. At the end of conversion process, the device reconnects the sampling capacitors to the AINP and AINM pins and enters an acquisition phase.

The integrated LDO allows the device to operate on a single supply,  $RV_{DD}$ . The device consumes only 21 mW, 16 mW, or 14 mW of power when operating at the rated maximum throughput of 1 MSPS, 500 kSPS, or 250 kSPS, respectively, with the internal reference buffer and LDO enabled.

The enhanced multiSPI™ digital interface is backward-compatible with traditional SPI protocol. Configurable features simplify board layout, timing, and firmware, and support high throughput at lower clock speeds, thus allowing an easy interface with a variety of microcontrollers, DSPs, and FPGAs.

The ADS891xB enables test and measurement, medical, and industrial applications to achieve fast, low-noise, low-distortion, low-power data acquisition in small form factors.

### 7.2 Functional Block Diagram

## 7.3 Feature Description

From a functional perspective, the device comprises four modules: the low-dropout regulator (LDO), the reference buffer (BUF), the converter (SAR ADC), and the interface (multiSPI digital interface), as shown in the [Functional Block Diagram](#) section.

The LDO module is powered by the  $RV_{DD}$  supply, and generates the bias voltage for internal circuit blocks of the device. The reference buffer module buffers the external reference voltage source from the dynamic, capacitive switching load present on the reference pins during the conversion process. The converter module samples and converts the analog input into an equivalent digital output code. The interface module facilitates communication and data transfer between the device and the host controller.

### 7.3.1 LDO Module

To enable single-supply operation, the device features an internal low-dropout regulator (LDO). The LDO is powered by the  $RV_{DD}$  supply, and the output is available on the two DECAP pins. This LDO output powers the critical analog blocks within the device, and must not be used for any other external purposes.

Short the two DECAP pins together, and decouple with the GND pin by placing a 1- $\mu$ F, X7R-grade, ceramic capacitor with a 10-V rating, as shown in [Figure 30](#). There is no upper limit on the value of the decoupling capacitor; however, a larger decoupling capacitor results in a longer power-up time for the device. See the [Layout](#) section for layout recommendations.

Figure 30. Internal LDO Connections

### 7.3.2 Reference Buffer Module

On the CONVST rising edge, the device moves from ACQ state to CONV state, and the internal capacitors are switched to the REFBUFOUT pins as per the successive approximation algorithm. Most of the switching charge required during the conversion process is provided by external decoupling capacitor  $C_{REFBUF}$ . If the charge lost from the  $C_{REFBUF}$  is not replenished before the next CONVST rising edge, the voltage on REFBUFOUT pins is less than  $V_{REFBUFOUT}$ . The subsequent conversion occurs with this different reference voltage, and causes a proportional error in the output code. The internal reference buffer of the device maintains the voltage on REFBUFOUT pins within 0.5-LSB of  $V_{REFBUFOUT}$ . All the performance characteristics of the device are specified with the internal reference buffer and specified values of  $C_{REFBUF}$  and  $R_{ESR}$ .

In burst-mode of operation, the device stays in ACQ state for a long duration of time and then performs a burst of conversions. During the acquisition state (ACQ), the sampling capacitor ( $C_S$ ) is connected to the differential input pins and no charge is drawn from the REFBUFOUT pins. However, during the very first conversion cycle, there is a step change in the current drawn from the REFBUFOUT pins. This sudden change in load triggers a transient settling response in the reference buffer. For a fixed input voltage, any transient settling error at the end of the conversion cycle results in a change in output codes over the subsequent conversions, as shown in [Figure 31](#). The internal reference buffer of the ADS89xxB, when used with the recommended values of  $C_{REFBUF}$  and  $R_{ESR}$ , keeps the transient settling error at the end of each conversion cycle within 0.5-LSB. Therefore, the device supports burst-mode of operation with every conversion result being as per the datasheet specifications.

## Feature Description (continued)

**Figure 31. ADC Output Codes in Burst-Mode Operation With Various ADC Reference Buffers**

Figure 32 shows the block diagram of the internal reference buffer.

**Figure 32. Internal Reference Buffer Block Diagram**

The input range for the device is set by the external voltage applied at the REFIN pin ( $V_{REF}$ ). The REFIN pin has electrostatic discharge (ESD) protection diodes to the RVDD and GND pins. For minimum input offset error (see  $E_{(IO)}$  specified in the [Electrical Characteristics](#)), set the REF\_SEL[2:0] bits to the value closest to  $V_{REF}$  (see the OFST\_CAL register).

The internal reference buffer has a typical gain of 1 V/V with minimal offset error (see  $V_{(RO)}$  specified in the [Electrical Characteristics](#)), and the output of the buffer is available between the REFBUFOUT pins and the REFM pins. Set the REF\_OFST[4:0] bits to add or subtract an intentional offset voltage (see the REF\_MRG register).

Figure 33 shows the external connections required for the internal reference buffer.

## Feature Description (continued)

Figure 33. External Connections for the Internal Reference Buffer

Select  $R_{REF\_FLT}$  and  $C_{REF\_FLT}$  to limit the broadband noise contribution from the external reference source. The device takes very little current,  $I_{REF}$ , from the REFIN pin (typically, 0.1  $\mu$ A). However, this current flows through  $R_{REF\_FLT}$  and may result in additional gain error.

Short the two REFBUFOUT pins externally. Short the two REFM pins to GND externally. As shown in Figure 33, place a combination of  $R_{ESR}$  and  $C_{REFBUF}$  (see the [Electrical Characteristics](#)) between the REFBUFOUT pins and the REFM pins as close to the device as possible. See the [Layout](#) section for layout recommendations.

### 7.3.3 Converter Module

As shown in Figure 34, the converter module samples the analog input signal (provided between the AINP and AINM pins), compares this signal with the reference voltage (between the pair of REFBUFOUT and REFM pins), and generates an equivalent digital output code.

The converter module receives  $\overline{RST}$  and CONVST inputs from the interface module, and outputs the ADCST signal and the conversion result back to the interface module.

Figure 34. Converter Module

## Feature Description (continued)

### 7.3.3.1 Sample-and-Hold Circuit

These devices support unipolar, fully differential, analog input signals. [Figure 35](#) shows a small-signal equivalent circuit of the sample-and-hold circuit. Each sampling switch is represented by a resistance ( $R_{S1}$  and  $R_{S2}$ , typically 50  $\Omega$ ) in series with an ideal switch ( $SW_1$  and  $SW_2$ ). The sampling capacitors,  $C_{S1}$  and  $C_{S2}$ , are typically 60 pF.

**Figure 35. Input Sampling Stage Equivalent Circuit**

During the acquisition process (ACQ state), both positive and negative inputs are individually sampled on  $C_{S1}$  and  $C_{S2}$ , respectively. During the conversion process (CNV state), the device converts for the voltage difference between the two sampled values:  $V_{AINP} - V_{AINM}$ .

Each analog input pin has electrostatic discharge (ESD) protection diodes to REFBUFOUT and GND. Keep the analog inputs within the specified range to avoid turning the diodes on.

[Equation 1](#) and [Equation 2](#) show the full-scale input range (FSR) and common-mode voltage ( $V_{CM}$ ), respectively, supported at the analog inputs for any external reference voltage provided on the REFIN pin ( $V_{REF}$ ).

$$FSR = \pm V_{REF} \quad (1)$$

$$V_{CM} = \left( \frac{V_{REF}}{2} \right) \pm 0.1 \text{ V} \quad (2)$$

## Feature Description (continued)

### 7.3.3.2 Internal Oscillator

The device family features an internal oscillator (OSC) that provides the conversion clock; see [Figure 34](#). The conversion duration is bound by the minimum and maximum value of  $t_{conv}$ , as specified in the [Switching Characteristics](#) table.

The interface module uses this internal clock (OSC), an external clock (provided by the host controller on the SCLK pin), or a combination of both the internal and external clocks, to execute the data transfer operations between the device and host controller; see the [Interface Module](#) section for more details.

### 7.3.3.3 ADC Transfer Function

The device family supports unipolar, fully differential analog inputs. The device output is in two's complement format. [Figure 36](#) and [Table 1](#) show the ideal transfer characteristics for the device.

The least significant bit (LSB) for the ADC is given by [Equation 3](#):

$$1 \text{ LSB} = \frac{\text{FSR}}{2^{18}} = 2 \times \frac{V_{\text{REF}}}{2^{18}} \quad (3)$$

Figure 36. Differential Transfer Characteristics

Table 1. Transfer Characteristics

| DIFFERENTIAL ANALOG INPUT VOLTAGE<br>(AINP – AINM) | OUTPUT CODE<br>(HEX) |

| 1 LSB                                              | 00001                |
| $> V_{\text{REF}} - 1 \text{ LSB}$                 | 1FFFF                |

### 7.3.4 Interface Module

The interface module facilitates the communication and data transfer between the device and the host controller. As shown in [Figure 37](#), the module consists of shift registers (both input and output), configuration registers, and a protocol unit.

**Figure 37. Interface Module**

The [Pin Configuration and Functions](#) section provides descriptions of the interface pins. The [Data Transfer Frame](#) section details the functions of shift registers, the SCLK counter, and the command processor. The [Data Transfer Protocols](#) section details supported protocols. The [Register Maps](#) section explains the configuration registers and bit settings.

## 7.4 Device Functional Modes

As shown in Figure 38, this device family supports three functional states: RST, ACQ, and CNV. The device state is determined by the status of the CONVST and  $\overline{\text{RST}}$  control signals provided by the host controller.

**Figure 38. Device Functional States**

### 7.4.1 RST State

The  $\overline{\text{RST}}$  pin is an asynchronous digital input for the device. To enter RST state, the host controller pulls the  $\overline{\text{RST}}$  pin low and keeps it low for the  $t_{\text{wl\_RST}}$  duration (as specified in the [Timing Requirements](#) table).

In RST state, all configuration registers (see the [Register Maps](#) section) are reset to their default values, the RVS pin remains low, and the SDO-x pins are Hi-Z.

To exit RST state, the host controller pulls the  $\overline{\text{RST}}$  pin high, with CONVST and SCLK held low and  $\overline{\text{CS}}$  held high, as shown in Figure 39. After a delay of  $t_{\text{d\_rst}}$ , the device enters ACQ state and the RVS pin goes high.

**Figure 39. Asynchronous Reset**

To operate the device in either ACQ or CNV state,  $\overline{\text{RST}}$  must be held high. With  $\overline{\text{RST}}$  held high, transitions on the CONVST pin determine the functional state of the device.

## Device Functional Modes (continued)

Figure 40 shows a typical conversion process. The internal ADCST signal goes low during conversion and goes high at the end of conversion. With  $\overline{\text{CS}}$  held high, RVS reflects the status of ADCST.

Figure 40. Typical Conversion Process

### 7.4.2 ACQ State

In ACQ state, the device acquires the analog input signal. The device enters ACQ state at power-up, when coming out of power down (See the [PD Control](#) section), after any asynchronous reset, and at the end of every conversion.

An  $\overline{\text{RST}}$  falling edge takes the device from ACQ state to RST state. A CONVST rising edge takes the device from ACQ state to CNV state.

### 7.4.3 CNV State

The device moves from ACQ state to CNV state on a rising edge of the CONVST pin. The conversion process uses an internal clock. The device ignores any further transitions on the CONVST signal until the ongoing conversion is complete (that is, during the time interval of  $t_{\text{conv}}$ ).

At the end of conversion, the device enters ACQ state. The cycle time for the device is given by [Equation 4](#):

$$t_{\text{cycle-min}} = t_{\text{conv}} + t_{\text{acq-min}} \quad (4)$$

#### NOTE

The conversion time,  $t_{\text{conv}}$ , varies within the specified limits of  $t_{\text{conv-min}}$  and  $t_{\text{conv-max}}$  (as specified in the [Switching Characteristics](#) table). After initiating a conversion, the host controller must monitor for a low-to-high transition on the RVS pin or wait for the  $t_{\text{conv-max}}$  duration to elapse before initiating a new operation (data transfer or conversion). If RVS is not monitored, substitute  $t_{\text{conv}}$  in [Equation 4](#) with  $t_{\text{conv-max}}$ .

## 7.5 Programming

This device family features nine configuration registers (as described in the [Register Maps](#) section). To access the internal configuration registers, these devices support the commands listed in [Table 2](#).

**Table 2. Supported Commands**

| B[21:17]               | B[16:8]         | B[7:0]                | COMMAND ACRONYM | COMMAND DESCRIPTION                                                   |
|------------------------|-----------------|-----------------------|-----------------|-----------------------------------------------------------------------|
| 00000                  | 000000000       | 00000000              | NOP             | No operation                                                          |
| 10000                  | <9-bit address> | <8-bit unmasked bits> | CLR_BITS        | Clear <8-bit unmasked bits> from <9-bit address>                      |
| 10001                  | <9-bit address> | 00000000              | RD_REG          | Read contents from the <9-bit address>                                |
| 10010                  | <9-bit address> | <8-bit data>          | WR_REG          | Write <8-bit data> to the <9-bit address>                             |
| 10011                  | <9-bit address> | <8-bit unmasked bits> | SET_BITS        | Set <8-bit unmasked bits> from <9-bit address>                        |
| 11111                  | 111111111       | 11111111              | NOP             | No operation                                                          |
| Remaining combinations | xxxxxxxxx       | xxxxxxxxx             | Reserved        | These commands are reserved and treated by the device as no operation |

These devices support two types of data transfer operations: *data write* (the host controller configures the device), and *data read* (the host controller reads data from the device).

Any data write to the device is always synchronous to the external clock provided on the SCLK pin. The WR\_REG command writes the 8-bit data into the 9-bit address specified in the command string. The CLR\_BITS command clears the specified bits (identified by 1) at the 9-bit address (without affecting the other bits), and the SET\_BITS command sets the specified bits (identified by 1) at the 9-bit address (without affecting the other bits).

The data read from the device can be synchronized to the same external clock or to an internal clock of the device by programming the configuration registers (see the [Data Transfer Protocols](#) section for details).

### 7.5.1 Output Data Word

In any data transfer frame, the contents of an internal, 22-bit, output data word are shifted out on the SDO pins. The D[21:4] bits of the 22-bit output data word for any frame  $F + 1$ , are determined by:

- Value of the DATA\_VAL bit applicable to frame  $F + 1$  (see the [DATA\\_CNTL register](#))
- The command issued in frame  $F$

If a valid RD\_REG command is executed in frame  $F$ , then the D[21:14] bits in frame  $F + 1$  reflect the contents of the selected register, and the D[13:0] bits are zeros.

If the DATA\_VAL bit for frame  $F + 1$  is set to 1, then the D[21:4] bits in frame  $F + 1$  are replaced by the DATA\_PATN[17:0] bits.

For all other combinations, the D[21:4] bits for frame  $F + 1$  are the latest conversion result.

[Figure 41](#) shows the output data word. [Figure 42](#) shows further details of the parity computation unit illustrated in [Figure 41](#).

**Figure 41. Output Data Word (D[21:0])**

**Figure 42. Parity Bits Computation**

With the PAR\_EN bit set to 0, the D[3] and D[2] bits of the output data word are set to 0 (default configuration).

When the PAR\_EN bit is set to 1, the device calculates the parity bits (FLPAR and FTPAR) and appends them as bits D[3] and D[2].

- FLPAR is the even parity calculated on bits D[21:4].
- FTPAR is the even parity calculated on the bits defined by FPAR\_LOC[1:0].

See the [DATA\\_CNTL register](#) for more details on the FPAR\_LOC[1:0] bit settings. Bits D[1:0] are set to 00b.

## 7.5.2 Data Transfer Frame

A data transfer frame between the device and the host controller is bounded between a  $\overline{\text{CS}}$  falling edge and the subsequent  $\overline{\text{CS}}$  rising edge. The host controller can initiate a data transfer frame (as shown in Figure 43) at any time irrespective of the status of the CONVST signal; however, the data read during such a data transfer frame is a function of relative timing between the CONVST and  $\overline{\text{CS}}$  signals.

**Figure 43. Data Transfer Frame**

For this discussion, assume that the CONVST signal remains low.

A typical data transfer frame  $F$  follows this order:

1. The host controller pulls  $\overline{\text{CS}}$  low to initiate a data transfer frame. On the  $\overline{\text{CS}}$  falling edge:
  - RVS goes low, indicating the beginning of the data transfer frame.
  - The SCLK counter is reset to 0.
  - The device takes control of the data bus. As shown in Figure 43, the 22-bit contents of the output data word (see Figure 41) are loaded in to the 22-bit output data register (ODR; see Figure 37).
  - The 22-bit input data register (IDR; see Figure 37) is reset to 000000h, corresponding to a NOP command.

2. During the frame, the host controller provides clocks on the SCLK pin. Inside the device:
  - For each SCLK capture edge, the SCLK counter is incremented and the data bit received on the SDI pin is shifted in to the IDR.
  - For each launch edge of the output clock (SCLK in this case), ODR data are shifted out on the selected SDO-x pins.
  - The status of the RVS pin depends on the output protocol selection (see the [Protocols for Reading From the Device](#) section).
3. The host controller pulls  $\overline{\text{CS}}$  high to end the data transfer frame. On the  $\overline{\text{CS}}$  rising edge:
  - The SDO-x pins go to Hi-Z.
  - RVS goes high (after a delay of  $t_{d\_CSR\text{DY}_r}$ ).
  - As illustrated in [Figure 43](#), the 22-bit contents of the IDR are transferred to the command processor (see [Figure 37](#)) for decoding and further action.

After pulling  $\overline{\text{CS}}$  high, the host controller monitors for a low-to-high transition on the RVS pin, or waits for the  $t_{d\_CSR\text{DY}_r}$  time (see the [Switching Characteristics](#) table) to elapse before initiating a new operation (data transfer or conversion). The delay,  $t_{d\_CSR\text{DY}_r}$ , for any data transfer frame  $F$  varies based on the data transfer operation executed in frame  $F$ .

At the end of data transfer frame  $F$ :

- If the SCLK counter is  $< 22$ , then the IDR captured less than 22 bits from the SDI. In this case, the device treats frame  $F$  as a *short command frame*. At the end of a short command frame, the IDR is not updated and the device treats the frame as a no operation (NOP) command.
- If the SCLK counter = 22, then the IDR captured exactly 22 bits from SDI. In this case, the device treats the frame  $F$  as a *optimal command frame*. At the end of an optimal command frame, the command processor decodes the 22-bit contents of the IDR as a valid command word.
- If the SCLK counter  $> 22$ , then the IDR captured more than 22 bits from the SDI; however, only the *last 22 bits* are retained. In this case, the device treats frame  $F$  as a *long command frame*. At the end of a long command frame, the command processor treats the 22-bit contents of the IDR as a valid command word. There is no restriction on the maximum number of clocks that can be provided within any data transfer frame  $F$ . However, as explained above, make sure that the last 22 bits shifted into the device before the  $\overline{\text{CS}}$  rising edge constitute the desired command.

In a short command frame, the write operation to the device is invalidated; however, the output data bits transferred during the short command frame are still valid output data. Therefore, the host controller can use such shorter data transfer frames to read only the required number of MSB bits from the 22-bit output data word. As shown in [Figure 41](#), an *optimal read frame* for the ADS891xB devices must read only the 18 MSB bits of the output data word. The length of an optimal read frame depends on the output protocol selection; see the [Protocols for Reading From the Device](#) section for more details.

#### NOTE

The previous example shows data-read and data-write operations synchronous to the external clock provided on the SCLK pin.

However, the device also supports data read operation synchronous to the internal clock; see the [Protocols for Reading From the Device](#) section for more details. In this case, while the ODR contents are shifted on the SDO (or SDOs) on the launch edge of the internal clock, the device continues to capture the SDI data into the IDR (and increment the SCLK counter) on SCLK capture edges.

### 7.5.3 Interleaving Conversion Cycles and Data Transfer Frames

The host controller operates the device at the desired throughput by interleaving the conversion cycles and the data transfer frames.

The cycle time of the device,  $t_{\text{cycle}}$ , is the time difference between two consecutive CONVST rising edges provided by the host controller. The response time of the device,  $t_{\text{resp}}$ , is the time difference between the host controller initiating conversion  $C$ , and the host controller receiving the complete result for conversion  $C$ .

Figure 44 shows three conversion cycles:  $C$ ,  $C + 1$ , and  $C + 2$ . Conversion  $C$  is initiated by a CONVST rising edge at time  $t = 0$ , and the conversion result becomes available for data transfer at  $t_{\text{conv}}$ . However, this result is loaded into the ODR only on the subsequent CS falling edge. This CS falling edge must be provided before the completion of conversion  $C + 1$  (that is, before  $t_{\text{cycle}} + t_{\text{conv}}$ ).

To achieve the rated performance specifications, the host controller must make sure that no digital signals toggle during the quiet acquisition time ( $t_{\text{qt\_acq}}$ ) and quiet aperture time ( $t_{\text{d\_cnvcap}}$ ). Any noise during  $t_{\text{d\_cnvcap}}$  may negatively affect the result of the ongoing conversion, whereas any noise during  $t_{\text{qt\_acq}}$  may negatively affect the result of the subsequent conversion.

Figure 44. Data Transfer Zones

This architecture allows for two distinct time zones (zone 1 and zone 2) to transfer data for each conversion. Zone 1 and zone 2 for conversion  $C$  are defined in Table 3.

Table 3. Data Transfer Zones Timing

| ZONE                      | STARTING TIME                             | ENDING TIME                                                |
|---------------------------|-------------------------------------------|------------------------------------------------------------|
| Zone 1 for conversion $C$ | $t_{\text{conv}}$                         | $t_{\text{cycle}} - t_{\text{qt\_acq}}$                    |
| Zone 2 for conversion $C$ | $t_{\text{cycle}} + t_{\text{d\_cnvcap}}$ | $t_{\text{cycle}} + t_{\text{cycle}} - t_{\text{qt\_acq}}$ |

The response time includes the conversion time and the data transfer time, and thus is a function of the selected data transfer zone.

Figure 45 and Figure 46 illustrate interleaving of three conversion cycles ( $C$ ,  $C + 1$ , and  $C + 2$ ) with three data transfer frames ( $F$ ,  $F + 1$ , and  $F + 2$ ) in zone 1 and in zone 2, respectively.

**Figure 45. Zone 1 Data Transfer**

**Figure 46. Zone 2 Data Transfer**

To achieve cycle time  $t_{\text{cycle}}$ , the read time in zone 1 is given by Equation 5:

$$t_{\text{read-Z1}} \leq t_{\text{cycle}} - t_{\text{conv}} - t_{\text{qt\_acq}} \quad (5)$$

For an optimal data transfer frame, Equation 5 results in an SCLK frequency given by Equation 6:

$$f_{\text{SCLK}} \geq \frac{18}{t_{\text{read-Z1}}} \quad (6)$$

Then, the zone 1 data transfer achieves a response time defined by Equation 7:

$$t_{\text{resp-Z1-min}} = t_{\text{conv}} + t_{\text{read-Z1}} \quad (7)$$

At lower SCLK speeds,  $t_{\text{read-Z1}}$  increases, resulting in slower response times and higher cycle times.

To achieve the same cycle time,  $t_{\text{cycle}}$ , the read time in zone 2 is given by Equation 8:

$$t_{\text{read-Z2}} \leq t_{\text{cycle}} - t_{\text{d\_cnvcap}} - t_{\text{qt\_acq}} \quad (8)$$

For an optimal data transfer frame, Equation 8 results in an SCLK frequency given by Equation 9:

$$f_{\text{SCLK}} \geq \frac{18}{t_{\text{read\_Z2}}} \quad (9)$$

Then, the zone 2 data transfer achieves a response time defined by Equation 10:

$$t_{\text{resp-Z2-min}} = t_{\text{cycle}} + t_{\text{d\_cnvcap}} + t_{\text{read-Z2}} \quad (10)$$

Any increase in  $t_{\text{read-Z2}}$  increases response time and may increase cycle time.

For a given cycle time, the zone 1 data transfer clearly achieves faster response time, but also requires a higher SCLK speed (as evident from Equation 5, Equation 6, and Equation 7); whereas, the zone 2 data transfer clearly requires a lower SCLK speed but has a slower response time (as evident from Equation 8, Equation 9, and Equation 10). For more information about benefits of zone 2 data transfer when using isolated digital interface or MCU refer to [TI TechNote - Simplify Isolation Designs Using an Enhanced-SPI ADC Interface](#).

#### NOTE

A data transfer frame can begin in zone 1, and then extend into zone 2; however, the host controller must make sure that no digital transitions occur during the  $t_{\text{qt\_acq}}$  and  $t_{\text{d\_cnvcap}}$  time intervals.

#### NOTE

For data transfer operations in zone 2 using the ADC-Clock-Master protocol (SDO\_MODE[1:0] = 11b), the device supports only the external-clock-echo option (SSYNC\_CLK\_SEL[1:0] = 00b); see Table 9.

### 7.5.4 Data Transfer Protocols

This device family features a multiSPI digital interface that allows the host controller to operate at slower SCLK speeds and still achieve the required throughput and response time. The multiSPI digital interface module offers three options to reduce the SCLK speed required for data transfer:

- Increase the width of the output data bus.
- Enable double data rate (DDR) transfer.
- Extended data transfer window, as shown in Figure 46.

These three options can be combined to achieve further reduction in SCLK speed.

There are various factors that limit the maximum SCLK frequency in a system.

Figure 47 shows the delays in the communication channel between the host controller and the device in a typical serial communication.

**Figure 47. Delays in Serial Communication**

For example, if  $t_{pcb\_CK}$  and  $t_{pcb\_SDO}$  are the delays introduced by the printed circuit board (PCB) traces for the serial clock and SDO signals,  $t_{d\_CKDO}$  is the clock-to-data delay of the device,  $t_{d\_ISO}$  is the propagation delay introduced by the digital isolator, and  $t_{su\_h}$  is the setup time specification of the host controller, then the total delay in the path is given by Equation 11:

$$t_{d\_total\_serial} = t_{pcb\_CK} + t_{d\_iso} + t_{d\_ckdo} + t_{d\_iso} + t_{pcb\_SDO} + t_{su\_h} \quad (11)$$

In a standard SPI protocol, the host controller and the device launch and capture data bits on alternate SCLK edges. Therefore, the  $t_{d\_total\_serial}$  delay must be kept to less than half of the SCLK duration. Equation 12 shows the fastest clock allowed by the SPI protocol:

$$f_{clk-SPI} \leq \frac{1}{2 \times t_{d\_total\_serial}} \quad (12)$$

Larger values of the  $t_{d\_total\_serial}$  delay restricts the maximum SCLK speed for the SPI protocol, resulting in higher read and response times, and can possibly limit the throughput.

Figure 48 shows a delay ( $t_{d\_delcap}$ ) introduced in the capture path (inside the host controller).

**Figure 48. Delayed Capture**

The total delay in the path modifies to Equation 13:

$$t_{d\_total\_serial} = t_{pcb\_CK} + t_{d\_iso} + t_{d\_ckdo} + t_{d\_iso} + t_{pcb\_SDO} + t_{su\_h} - t_{d\_delcap} \quad (13)$$

This reduction in total delay allows the SPI protocol to operate at higher clock speeds.

The multiSPI digital interface module offers two additional options to remove the restriction on the SCLK speed:

- Early data launch (EDL) mode of operation  
In EDL mode, the device launches the output data on SDO-x pin (or pins) half a clock earlier compared to the standard SPI protocol. Therefore, Equation 12 modifies to Equation 14:

$$f_{\text{clk-SPI}} \leq \frac{1}{t_{\text{d\_total-serial}}} \quad (14)$$

The reduction in total delay allows the serial interface to operate at higher clock speeds.

- ADC-Clock-Master (*source-synchronous*) mode of operation  
As illustrated in Figure 49, in ADC-Clock-Master mode, the device provides a synchronous output clock (on the RVS pin) along with the output data (on the SDO-x pins).

**Figure 49. Delays in ADC-Clock-Master (Source-Synchronous) Mode**

For negligible values of  $t_{\text{off\_STRDO}}$ , the total delay in the path for a source-synchronous data transfer, is given by Equation 15:

$$t_{\text{d\_total\_srcsync}} = t_{\text{pcb\_RVS}} - t_{\text{pcb\_SDO}} + t_{\text{su\_h}} \quad (15)$$

As shown by the difference between Equation 11 and Equation 15, using ADC-Clock-Master mode completely eliminates the effect of isolator delays ( $t_{\text{d\_ISO}}$ ) and clock-to-data delays ( $t_{\text{d\_CKDO}}$ ); typically, the largest contributors in the overall delay computation.

Furthermore, the actual values of  $t_{\text{pcb\_RVS}}$  and  $t_{\text{pcb\_SDO}}$  do not matter. In most cases, the  $t_{\text{d\_total\_srcsync}}$  delay can be kept at a minimum by routing the RVS and SDO lines together on the PCB. Therefore, the ADC-Clock-Master mode allows the data transfer between the host controller and the device to operate at much higher SCLK speeds. For more information about using ADC-Clock-Master mode to achieve fast SCLK speeds, with an isolated interface or high routing delays, see [Optimizing Data Transfer on High-Resolution, High Throughput Data Converters](#). Zone 2 data transfer also enables longer quiet time for analog input settling, and is discussed in [Improving Input Settling for Precision Data Converters](#).

### 7.5.4.1 Protocols for Configuring the Device

As shown in Table 4, the host controller can use any of the four legacy, SPI-compatible protocols (SPI-00-S, SPI-01-S, SPI-10-S, or SPI-11-S) to write data to the device.

**Table 4. SPI Protocols for Configuring the Device**

| PROTOCOL | SCLK POLARITY<br>(At CS Falling Edge) | SCLK PHASE<br>(Capture Edge) | SDI_CNTL | SDO_CNTL | NO. OF SCLK<br>(Optimal Command<br>Frame) | TIMING<br>DIAGRAM |
|----------|---------------------------------------|------------------------------|----------|----------|-------------------------------------------|-------------------|
| SPI-00-S | Low                                   | Rising                       | 00h      | 00h      | 22                                        | Figure 50         |
| SPI-01-S | Low                                   | Falling                      | 01h      | 00h      | 22                                        | Figure 51         |
| SPI-10-S | High                                  | Falling                      | 02h      | 00h      | 22                                        | Figure 52         |
| SPI-11-S | High                                  | Rising                       | 03h      | 00h      | 22                                        | Figure 53         |

At power-up or after coming out of any asynchronous reset, the device supports the SPI-00-S protocol for data-read and data-write operations.

To select a different SPI-compatible protocol, program the SDI\_MODE[1:0] bits in the SDI\_CNTL register. This first write operation must adhere to the SPI-00-S protocol. Any subsequent data transfer frames must adhere to the newly selected protocol.

Figure 50 to Figure 53 detail the four protocols using an optimal command frame; see the Timing Requirements and Switching Characteristics tables for associated timing parameters.

#### NOTE

As explained in the Data Transfer Frame section, a valid write operation to the device requires a minimum of 22 SCLKs to be provided within a data transfer frame.

Any data write operation to the device must continue to follow the SPI-compatible protocol selected in the SDI\_CNTL register, irrespective of the protocol selected for the data-read operation.

**Figure 50. SPI-00-S Protocol, Optimal Command Frame**

**Figure 51. SPI-01-S Protocol, Optimal Command Frame**

**Figure 52. SPI-10-S Protocol, Optimal Command Frame**

**Figure 53. SPI-11-S Protocol, Optimal Command Frame**

### 7.5.4.2 Protocols for Reading From the Device

The protocols for the data-read operation can be broadly classified into three categories:

1. Legacy, SPI-compatible (SPI-xy-S) protocol
2. SPI-compatible protocols with bus width options (SPI-xy-D and SPI-xy-Q)
3. Source-synchronous (SRC) protocols

#### 7.5.4.2.1 Legacy, SPI-Compatible (SYS-xy-S) Protocols

As shown in [Table 5](#), the host controller can use any of the four legacy, SPI-compatible protocols (SPI-00-S, SPI-01-S, SPI-10-S, or SPI-11-S) to read data from the device.

**Table 5. SPI Protocols for Reading From the Device**

| PROTOCOL | SCLK POLARITY (At CS Falling Edge) | SCLK PHASE (Capture Edge) | MSB BIT LAUNCH EDGE          | SDI_CNTL | SDO_CNTL | NO. OF SCLK (Optimal Read Frame) | TIMING DIAGRAM            |
|----------|------------------------------------|---------------------------|------------------------------|----------|----------|----------------------------------|---------------------------|
| SPI-00-S | Low                                | Rising                    | $\overline{CS}$ falling      | 00h      | 00h      | 18                               | <a href="#">Figure 54</a> |
| SPI-01-S | Low                                | Falling                   | 1 <sup>st</sup> SCLK rising  | 01h      | 00h      | 18                               | <a href="#">Figure 55</a> |
| SPI-10-S | High                               | Falling                   | $\overline{CS}$ falling      | 02h      | 00h      | 18                               | <a href="#">Figure 56</a> |
| SPI-11-S | High                               | Rising                    | 1 <sup>st</sup> SCLK falling | 03h      | 00h      | 18                               | <a href="#">Figure 57</a> |

At power-up or after coming out of any asynchronous reset, the device supports the SPI-00-S protocol for data-read and data-write operations. To select a different SPI-compatible protocol for both the data transfer operations:

1. Program the SDI\_MODE[1:0] bits in the [SDI\\_CNTL](#) register. This first write operation must adhere to the SPI-00-S protocol. Any subsequent data transfer frames must adhere to the newly selected protocol.
2. Set the SDO\_MODE[1:0] bits = 00b in the [SDO\\_CNTL](#) register.

[Figure 54](#) to [Figure 57](#) explain the details of the four protocols using an optimal command frame to read all 22 bits of the output data word. [Table 5](#) shows the number of SCLK required in an optimal read frame for the different output protocol selections.

**Figure 54. SPI-00-S Protocol, 22 SCLKs**

**Figure 55. SPI-01-S Protocol, 22 SCLKs**

**Figure 56. SPI-10-S Protocol, 22 SCLKs**

**Figure 57. SPI-11-S Protocol, 22 SCLKs**

For SDI\_MODE[1:0] = 00b or 10b, the device supports an *Early Data Launch* (EDL) option. Set SDO\_MODE[1:0] = 01b in the [SDO\\_CNTL register](#) to enable the feature (see [Table 6](#)). Setting SDO\_MODE[1:0] = 01b has no effect if SDI\_MODE[1:0] = 01b or 11b.

**Table 6. SPI Protocols with Early Data Launch**

| PROTOCOL     | SCLK POLARITY<br>(At $\overline{CS}$ Falling Edge) | SCLK PHASE<br>(Capture Edge) | MSB BIT LAUNCH<br>EDGE  | SDI_CNTL | SDO_CNTL | NO. OF SCLK<br>(Optimal Read Frame) | TIMING<br>DIAGRAM         |
|--------------|----------------------------------------------------|------------------------------|-------------------------|----------|----------|-------------------------------------|---------------------------|
| SPI-00-S-EDL | Low                                                | Rising                       | $\overline{CS}$ falling | 00h      | 01h      | 18                                  | <a href="#">Figure 54</a> |
| SPI-10-S-EDL | High                                               | Falling                      | $\overline{CS}$ falling | 02h      | 01h      | 18                                  | <a href="#">Figure 56</a> |

As shown in [Figure 58](#), and [Figure 59](#), the device launches the output data bit on the SDO-0 pin half clock earlier compared to the standard SPI protocol.

**Figure 58. SPI-00-S-EDL Protocol, 22 SCLKs**

**Figure 59. SPI-10-S-EDL Protocol, 22 SCLKs**

When using these SPI-compatible protocols, the RVS output remains low throughout the data transfer frame; see the [Timing Requirements](#) and [Switching Characteristics](#) tables for associated timing parameters.

With SDO\_CNTL[7:0] = 00h or 01h, if the host controller uses a long data transfer frame, the device exhibits daisy-chain operation (see the [Multiple Devices: Daisy-Chain Topology](#) section).

**NOTE**

Use SPI-compatible protocols to execute the RD\_REG, WR\_REG, CLR\_BITS, and SET\_BITS commands specified in [Table 2](#).

### 7.5.4.2.2 SPI-Compatible Protocols with Bus Width Options

The device provides an option to increase the SDO bus width from one bit (default, single SDO) to two bits (dual SDO) or four bits (quad SDO) when operating with any of the four legacy, SPI-compatible protocols.

Set the SDO\_WIDTH[1:0] bits in the [SDO\\_CNTL register](#) to select the SDO bus width. The SCLK launch edge depends on the SPI protocol selection (as shown in [Table 7](#)).

**Table 7. SPI-Compatible Protocols with Bus Width Options**

| PROTOCOL | SCLK POLARITY<br>(At CS Falling Edge) | SCLK PHASE<br>(Capture Edge) | MSB BIT<br>LAUNCH EDGE  | SDI_CNTL | SDO_CNTL | #SCLK<br>(Optimal Read Frame) | TIMING<br>DIAGRAM         |
|----------|---------------------------------------|------------------------------|-------------------------|----------|----------|-------------------------------|---------------------------|
| SPI-00-D | Low                                   | Rising                       | $\overline{CS}$ falling | 00h      | 08h      | 9                             | <a href="#">Figure 60</a> |
| SPI-01-D | Low                                   | Falling                      | First SCLK rising       | 01h      | 08h      | 9                             | <a href="#">Figure 61</a> |
| SPI-10-D | High                                  | Falling                      | $\overline{CS}$ falling | 02h      | 08h      | 9                             | <a href="#">Figure 62</a> |
| SPI-11-D | High                                  | Rising                       | First SCLK falling      | 03h      | 08h      | 9                             | <a href="#">Figure 63</a> |
| SPI-00-Q | Low                                   | Rising                       | $\overline{CS}$ falling | 00h      | 0Ch      | 5                             | <a href="#">Figure 64</a> |
| SPI-01-Q | Low                                   | Falling                      | First SCLK rising       | 01h      | 0Ch      | 5                             | <a href="#">Figure 65</a> |
| SPI-10-Q | High                                  | Falling                      | $\overline{CS}$ falling | 02h      | 0Ch      | 5                             | <a href="#">Figure 66</a> |
| SPI-11-Q | High                                  | Rising                       | First SCLK falling      | 03h      | 0Ch      | 5                             | <a href="#">Figure 67</a> |

In dual-SDO mode (SDO\_WIDTH[1:0] = 10b), two bits of data are launched on the two SDO pins (SDO-0 and SDO-1) on every SCLK launch edge.

In quad-SDO mode (SDO\_WIDTH[1:0] = 11b), four bits of data are launched on the four SDO pins (SDO-0, SDO-1, SDO-2, and SDO-3) on every SCLK launch edge.

**Figure 60. SPI-00-D Protocol**

**Figure 61. SPI-01-D Protocol**

**Figure 62. SPI-10-D Protocol**

**Figure 63. SPI-11-D Protocol**

**Figure 64. SPI-00-Q Protocol**

**Figure 65. SPI-01-Q Protocol**

**Figure 66. SPI-10-Q Protocol**

**Figure 67. SPI-11-Q Protocol**

For SDI\_MODE[1:0] = 00b or 10b, the device supports an early data launch (EDL) option. Set SDO\_MODE[1:0] = 01b in the [SDO\\_CNTL register](#) to enable the feature (see [Table 8](#)). Setting SDO\_MODE[1:0] = 01b has no effect if SDI\_MODE[1:0] = 01b or 11b.

**Table 8. SPI Protocols with Early Data Launch**

| PROTOCOL     | SCLK POLARITY (At CS Falling Edge) | SCLK PHASE (Capture Edge) | MSB BIT LAUNCH EDGE            | SDI_CNTL | SDO_CNTL | NO. OF SCLK (Optimal Read Frame) | TIMING DIAGRAM            |
|--------------|------------------------------------|---------------------------|--------------------------------|----------|----------|----------------------------------|---------------------------|
| SPI-00-D-EDL | Low                                | Rising                    | $\overline{\text{CS}}$ falling | 00h      | 09h      | 9                                | <a href="#">Figure 60</a> |
| SPI-10-D-EDL | High                               | Falling                   | $\overline{\text{CS}}$ falling | 02h      | 09h      | 9                                | <a href="#">Figure 62</a> |
| SPI-00-Q-EDL | Low                                | Rising                    | $\overline{\text{CS}}$ falling | 00h      | 0Dh      | 5                                | <a href="#">Figure 64</a> |
| SPI-10-Q-EDL | High                               | Falling                   | $\overline{\text{CS}}$ falling | 02h      | 0Dh      | 5                                | <a href="#">Figure 66</a> |

As shown in [Figure 58](#), and [Figure 59](#), the device launches the output data bits on the SDO-x pins half clock earlier compared to the standard SPI protocol.

**Figure 68. SPI-00-D-EDL Protocol**

**Figure 69. SPI-10-D-EDL Protocol**

**Figure 70. SPI-00-Q-EDL Protocol**

**Figure 71. SPI-10-Q-EDL Protocol**

When using any of the SPI-compatible protocols, the RVS output remains low throughout the data transfer frame; see the [Timing Requirements](#) and [Switching Characteristics](#) tables for associated timing parameters.

[Figure 60](#) to [Figure 71](#) illustrate how the wider data bus allows the host controller to read all 22 bits of the output data word using shorter data transfer frames. [Table 7](#) and [Table 8](#) show the number of SCLK required in an optimal read frame for the different output protocol selections.

#### NOTE

With SDO\_CNTL[7:0]  $\neq$  00h or 01h, a long data transfer frame does not result in daisy-chain operation. On SDO pin (or pins), the 22 bits of output data word are followed by zeros.

### 7.5.4.2.3 Source-Synchronous (SRC) Protocols

As described in the [Data Transfer Protocols](#) section, the multiSPI digital interface supports an ADC-Clock-Master or a *source-synchronous* mode of data transfer between the device and host controller. In this mode, the device provides an output clock that is synchronous with the output data. Furthermore, the host controller can also select the output clock source, data bus width, and data transfer rate.

#### 7.5.4.2.3.1 Output Clock Source Options with SRC Protocols

In all SRC protocols, the RVS pin provides the output clock. The device allows this output clock to be synchronous to either the external clock provided on the SCLK pin or to the internal clock of the device. Furthermore, this internal clock can be divided by a factor of two or four to lower the data rates.

As shown in [Figure 72](#), set the SSYNC\_CLK\_SEL[1:0] bits in the [SDO\\_CNTL](#) register to select the output clock source.

**Figure 72. Output Clock Source Options With SRC Protocols**

#### 7.5.4.2.3.2 Bus Width Options With SRC Protocols

The device provides an option to increase the SDO bus width from one bit (default, single SDO) to two bits (dual SDO) or to four bits (quad SDO) when operating with any of the SRC protocols. Set the SDO\_WIDTH[1:0] bits in the [SDO\\_CNTL register](#) to select the SDO bus width.

In dual-SDO mode (SDO\_WIDTH[1:0] = 10b), two bits of data are launched on the two SDO pins (SDO-0 and SDO-1) on every SCLK rising edge.

In quad-SDO mode (SDO\_WIDTH[1:0] = 11b), four bits of data are launched on the four SDO pins (SDO-0, SDO-1, SDO-2, and SDO-3) on every SCLK rising edge.

#### 7.5.4.2.3.3 Output Data Rate Options With SRC Protocols

The device provides an option to transfer the data to the host controller at a single data rate (default, SDR) or at a double data rate (DDR). Set the DATA\_RATE bit in the [SDO\\_CNTL register](#) to select the data transfer rate.

In SDR mode (DATA\_RATE = 0b), the RVS pin toggles from low to high, and the output data bits are launched on the SDO pins on the output clock rising edge.

In DDR mode (DATA\_RATE = 1b), the RVS pin toggles (from low-to-high or high-to-low), and the output data bits are launched on the SDO pins on every output clock edge, starting with the first rising edge.

The device supports all 24 combinations of output clock source, bus width, and output data rate, as shown in [Table 9](#).

**Table 9. SRC Protocol Combinations**

| PROTOCOL   | OUTPUT CLOCK SOURCE       | BUS WIDTH | OUTPUT DATA RATE | SDI_CNTL                             | SDO_CNTL | #OUTPUT CLOCK (Optimal Read Frame) | TIMING DIAGRAM            |
|------------|---------------------------|-----------|------------------|--------------------------------------|----------|------------------------------------|---------------------------|
| SRC-EXT-SS | SCLK <sup>(1)</sup>       | Single    | SDR              | 00h, 01h, 02h, or 03h <sup>(2)</sup> | 03h      | 9                                  | <a href="#">Figure 73</a> |
| SRC-INT-SS | INTCLK <sup>(3)</sup>     | Single    | SDR              |                                      | 43h      | 9                                  | <a href="#">Figure 74</a> |
| SRC-IB2-SS | INTCLK / 2 <sup>(3)</sup> | Single    | SDR              |                                      | 83h      | 9                                  |                           |
| SRC-IB4-SS | INTCLK / 4 <sup>(3)</sup> | Single    | SDR              |                                      | C3h      | 9                                  |                           |
| SRC-EXT-DS | SCLK <sup>(1)</sup>       | Dual      | SDR              |                                      | 0Bh      | 9                                  | <a href="#">Figure 77</a> |
| SRC-INT-DS | INTCLK <sup>(3)</sup>     | Dual      | SDR              |                                      | 4Bh      | 9                                  | <a href="#">Figure 78</a> |
| SRC-IB2-DS | INTCLK / 2 <sup>(3)</sup> | Dual      | SDR              |                                      | 8Bh      | 9                                  |                           |
| SRC-IB4-DS | INTCLK / 4 <sup>(3)</sup> | Dual      | SDR              |                                      | CBh      | 9                                  |                           |
| SRC-EXT-QS | SCLK <sup>(1)</sup>       | Quad      | SDR              |                                      | 0Fh      | 5                                  | <a href="#">Figure 81</a> |
| SRC-INT-QS | INTCLK <sup>(3)</sup>     | Quad      | SDR              |                                      | 4Fh      | 5                                  | <a href="#">Figure 82</a> |

(1) The EXTCLK option is not recommended when operating with DV<sub>DD</sub> < 2.35 V.

(2) Any of the four values can be used; see the [Protocols for Configuring the Device](#) section for more information.

(3) The device supports INTCLK, INTCLK / 2, and INTCLK / 4 options only for data transfer operations in zone 1. The EXTCLK option is supported in zone 1 and zone 2; see [Figure 44](#).

Figure 73 to Figure 84 show the details of various source synchronous protocols. Table 9 shows the number of output clocks required in an optimal read frame for the different output protocol selections.

## 7.5.5 Device Setup

The multiSPI digital interface and the device configuration registers offer multiple operation modes. This section describes how to select the hardware connection topology to meet different system requirements.

### 7.5.5.1 Single Device: All multiSPI Options

Figure 85 shows the connections between a host controller and a single device in order to exercise all options provided by the multiSPI digital interface.

Copyright © 2016, Texas Instruments Incorporated

**Figure 85. MultiSPI Digital Interface, All Pins**

### 7.5.5.2 Single Device: Minimum Pins for a Standard SPI Interface

Figure 86 shows the minimum-pin interface for applications using a standard SPI protocol.

Copyright © 2016, Texas Instruments Incorporated

**Figure 86. SPI Interface, Minimum Pins**

The  $\overline{CS}$ , SCLK, SDI, and SDO-0 pins constitute a standard SPI port of the host controller. The CONVST pin is tied to  $\overline{CS}$ , and the  $\overline{RST}$  pin is tied to DVDD. The SDO-1, SDO-2, and SDO-3 pins have no external connections. The following features are also available:

- Control the CONVST pin independently to get additional timing flexibility.
- Control  $\overline{RST}$  pin independently to add asynchronous reset functionality.
- Monitor the RVS pin for additional timing benefits.

### 7.5.5.3 Multiple Devices: Daisy-Chain Topology

A typical connection diagram showing multiple devices in a daisy-chain topology is shown in [Figure 87](#).

**Figure 87. Daisy-Chain Connections**

The CONVST,  $\overline{CS}$ , and SCLK inputs of all devices are connected together and controlled by a single CONVST,  $\overline{CS}$ , and SCLK pin of the host controller, respectively. The SDI input pin of the first device in the chain (Device 1) is connected to the SDO pin of the host controller, the SDO-0 output pin of Device 1 is connected to the SDI input pin of Device 2, and so on. The SDO-0 output pin of the last device in the chain (Device N) is connected to the SDI pin of the host controller.

To operate multiple devices in a daisy-chain topology, the host controller sets the configuration registers in each device with identical values and operates with any of the legacy, SPI-compatible protocols for data-read and data-write operations (SDO\_CNT[7:0] = 00h or 01h). With these configurations settings, the 22-bit ODR and 22-bit IDR registers in each device collapse to form a single, 22-bit unified shift register (USR) per device, as shown in [Figure 88](#).

**Figure 88. Unified Shift Register**

All devices in the daisy-chain topology sample the respective device analog input signals on the CONVST rising edge. The data transfer frame starts with a  $\overline{CS}$  falling edge. On each SCLK launch edge, every device in the chain shifts out the MSB of the respective USR on to the respective SDO-0 pin. On every SCLK capture edge, each device in the chain shifts in data received on the respective SDI pin as the LSB bit of the respective USR. Therefore, in a daisy-chain configuration, the host controller receives the data of Device  $N$ , followed by the data of Device  $N - 1$ , and so on (MSB-first). On the  $\overline{CS}$  rising edge, each device decodes the contents in the respective USR, and takes appropriate action.

A typical timing diagram for three devices connected in daisy-chain topology using the SPI-00-S protocol is shown in Figure 89.

**Figure 89. Three-Device, Daisy-Chain Timing**

In daisy-chain topology, the overall throughput of the system is proportionally reduced as more devices are connected in the daisy-chain.

#### NOTE

For  $N$  devices connected in daisy-chain topology, an optimal data transfer frame must contain  $22 \times N$  SCLK capture edges. For a longer data transfer frame (number of SCLK in the frame  $> 22 \times N$ ), the host controller must appropriately align the configuration data for each device before bringing  $\overline{CS}$  high. A shorter data transfer frame (number of SCLK in the frame  $< 22 \times N$ ) might result in an erroneous device configuration, and *must be avoided*.

### 7.5.5.4 Multiple Devices: Star Topology

A typical connection diagram showing multiple devices in a star topology is shown in [Figure 90](#). The CONVST, SDI, and SCLK inputs of all devices are connected together, and are controlled by a single CONVST, SDO, and SCLK pin of the host controller, respectively. Similarly, the SDO output pin of all devices are tied together and connected to the a single SDI input pin of the host controller. The CS input pin of each device is individually controlled by separate CS control lines from the host controller.

Copyright © 2016, Texas Instruments Incorporated

**Figure 90. Star-Topology Connection**

The timing diagram for three devices connected in the star topology is shown in [Figure 91](#). In order to avoid any conflict related to multiple devices driving the SDO line at the same time, make sure that the host controller pulls down the CS signal for *only one device at any particular time*.

**Figure 91. Three-Device, Star Connection Timing**

## 7.6 Register Maps

### 7.6.1 Device Configuration and Register Maps

The device features nine configuration registers, mapped as described in [Table 10](#).

**Table 10. Configuration Registers Mapping**

| ADDRESS | REGISTER NAME             | REGISTER DESCRIPTION                                     |
|---------|---------------------------|----------------------------------------------------------|
| 004h    | <a href="#">PD_CNTL</a>   | Low-power modes control                                  |
| 008h    | <a href="#">SDI_CNTL</a>  | SDI input protocol selection                             |
| 00Ch    | <a href="#">SDO_CNTL</a>  | SDO output protocol selection                            |
| 010h    | <a href="#">DATA_CNTL</a> | Output data word configuration                           |
| 014h    | <a href="#">PATN_LSB</a>  | Eight least significant bits (LSB) of the output pattern |
| 015h    | <a href="#">PATN_MID</a>  | Eight middle bits of the output pattern                  |
| 016h    | <a href="#">PATN_MSB</a>  | Four most significant bits (MSB) of the output pattern   |
| 020h    | <a href="#">OFST_CAL</a>  | Offset calibration                                       |
| 030h    | <a href="#">REF_MRG</a>   | Reference margin                                         |

#### 7.6.1.1 PD\_CNTL Register (address = 04h) [reset = 00h]

This register controls the low-power modes offered by the device.

**Figure 92. PD\_CNTL Register**

| 7    | 6    | 5    | 4    | 3    | 2         | 1      | 0    |
|------|------|------|------|------|-----------|--------|------|

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11. PD\_CNTL Register Field Descriptions**

| Bit | Field     | Type | Reset  | Description                                                                                                                                           |
|-----|-----------|------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7-3 | 0         | R    | 00000b | Reserved bits. Reads return 00000b.                                                                                                                   |
| 2   | PD_REFBUF | R/W  | 0b     | This bit powers down the internal reference buffer.<br>0b = Internal reference buffer is powered up<br>1b = Internal reference buffer is powered down |
| 1   | PD_ADC    | R/W  | 0b     | This bit powers down the converter module.<br>0b = converter module is powered up<br>1b = converter module is powered down                            |
| 0   | 0         | R    | 0b     | Reserved bits. Do not write. Reads return 0b.                                                                                                         |

To power-down the converter module, set the PD\_ADC bit in the [PD\\_CNTL register](#). The converter module powers down on the rising edge of  $\overline{CS}$ . To power-up the converter module, reset the PD\_ADC bit in the [PD\\_CNTL register](#). The converter module starts to power-up on the rising edge of  $\overline{CS}$ . Wait for  $t_{PU\_ADC}$  before initiating any conversion or data transfer operation.

To power-down the internal reference buffer, set the PD\_REFBUF bit in the [PD\\_CNTL register](#). The internal reference buffer powers down on the rising edge of  $\overline{CS}$ . To power-up the internal reference buffer, reset the PD\_REFBUF bit in the [PD\\_CNTL register](#). The internal reference buffer starts to power-up on the rising edge of  $\overline{CS}$ . Wait for  $t_{PU\_REFBUF}$  before initiating any conversion.

### 7.6.1.2 SDI\_CNTL Register (address = 008h) [reset = 00h]

This register selects the SPI protocol for writing data to the device.

**Figure 93. SDI\_CNTL Register**

| 7    | 6    | 5    | 4    | 3    | 2    | 1             | 0 |
|------|------|------|------|------|------|---------------|---|

(1) The actual  $V_{\text{REFBUFOUT}}$  value may vary by  $\pm 10\%$  from [Table 20](#)

## 8 Application and Implementation

### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 8.1 Application Information

The two primary circuits required to maximize the performance of a high-precision, successive approximation register (SAR), analog-to-digital converter (ADC) are the input driver and the reference driver circuits. This section presents general principles for designing these circuits, followed by an application circuit designed using the ADS891xB.

#### 8.1.1 ADC Reference Driver

The external reference source must provide low-drift and very accurate voltage at the REFIN pin of the ADS891xB. The output broadband noise of most references can be in the order of a few hundred  $\mu\text{V}_{\text{RMS}}$ . Therefore, to prevent any degradation in the noise performance of the ADC, appropriately filter the output of the voltage reference by using a low-pass filter with a cutoff frequency of a few hundred hertz.

The internal reference buffer of the ADS891xB provides the dynamic load posed on the REFBUFOUT pin during the conversion process. Decouple the REFBUFOUT pin with the REFM pin using the recommended  $C_{\text{REFBUF}}$  and  $R_{\text{ESR}}$ . See the [Layout](#) section for layout recommendations.

#### 8.1.2 ADC Input Driver

The input driver circuit for a high-precision ADC mainly consists of two parts: a driving amplifier and a charge kickback filter. The amplifier is used for signal conditioning of the input signal and the low output impedance of the amplifier provides a buffer between the signal source and the switched capacitor inputs of the ADC. The charge kickback filter helps attenuate the sampling charge injection from the switched-capacitor input stage of the ADC, and band-limits the wideband noise contributed by the front-end circuit. Careful design of the front-end circuit is critical to meet the linearity and noise performance of the ADS891xB.

##### 8.1.2.1 Charge-Kickback Filter

The charge-kickback filter is an RC filter at the input pins of the ADC that filters the broadband noise from the front-end drive circuitry, and attenuates the sampling charge injection from the switched-capacitor input stage of the ADC. A filter capacitor,  $C_{\text{FLT}}$ , is connected from each input pin of the ADC to the ground (as shown in [Figure 102](#)). This capacitor helps reduce the sampling charge injection and provides a charge bucket to quickly charge the internal sample-and-hold capacitors during the acquisition process. Generally, the value of this capacitor must be at least 20 times the specified value of the ADC sampling capacitance. For the ADS891xB, the input sampling capacitance is equal to 60 pF; therefore, for optimal performance, keep  $C_{\text{FLT}}$  greater than 1.2 nF. This capacitor must be a COG- or NPO-type. The type of dielectric used in COG or NPO ceramic capacitors provides the most stable electrical properties over voltage, frequency, and temperature changes.

Figure 102. Charge Kickback Filter Configuration

## Application Information (continued)

Driving capacitive loads can degrade the phase margin of the input amplifier, thus making the amplifier marginally unstable. To avoid amplifier stability issues, series isolation resistors ( $R_{FLT}$ ) are used at the output of the amplifiers. A higher value of  $R_{FLT}$  helps with amplifier stability, but adds distortion as a result of interactions with the nonlinear input impedance of the ADC. Distortion increases with source impedance, input signal frequency, and input signal amplitude. Therefore, the selection of  $R_{FLT}$  requires balancing the stability of the driver amplifier and distortion performance of the design. Always verify the stability and settling behavior of the driving amplifier and charge-kickback filter by TINA-TI™ SPICE simulation. Keep the tolerance of the selected resistors less than 1% to keep the inputs balanced.

### 8.1.2.2 Input Amplifier Selection

Selection criteria for the input amplifiers is highly dependent on the input signal type, as well as the performance goals, of the data acquisition system. Some key amplifier specifications to consider when selecting an appropriate amplifier to drive the inputs of the ADC are:

- **Small-signal bandwidth.** Select the small-signal bandwidth of the input amplifiers to be as high as possible after meeting the power budget of the system. Higher bandwidth reduces the closed-loop output impedance of the amplifier, thus allowing the amplifier to more easily drive the ADC sample-and-hold capacitor and the RC filter ([Charge-Kickback Filter](#)) at the inputs of the ADC. Higher bandwidth amplifiers offer faster settling times while driving the capacitive load of the charge-kickback filter, thus reducing harmonic distortion at higher input frequencies. In order to maintain the overall stability of the input driver circuit, select the amplifier with a unity gain bandwidth (UGB) as described in [Equation 16](#):

$$UGB \geq 4 \times \left( \frac{1}{2\pi \times R_{FLT} \times C_{FLT}} \right) \quad (16)$$

- **Distortion.** Both the ADC and the input driver introduce distortion in a data acquisition block. To make sure that the distortion performance of the data acquisition system is not limited by the front-end circuit, the distortion of the input driver must be at least 10 dB less than the distortion of the ADC, as shown in [Equation 17](#).

$$THD_{AMP} \leq THD_{ADC} - 10 \text{ (dB)} \quad (17)$$

- **Noise.** Noise contribution of the front-end amplifiers must be as low as possible to prevent any degradation in SNR performance of the system. Generally, to make sure that the noise performance of the data acquisition system is not limited by the front-end circuit, the total noise contribution from the front-end circuit must be kept below 20% of the input-referred noise of the ADC. Noise from the input driver circuit is band-limited by designing a low cutoff frequency, charge-kickback filter, as explained in [Equation 18](#).

$$N_G \times \sqrt{2} \times \sqrt{\left( \frac{V_{1/f\_AMP\_PP}}{6.6} \right)^2 + e_{n\_RMS}^2 \times \frac{\pi}{2} \times f_{-3dB}} \leq \frac{1}{5} \times \frac{V_{REF}}{\sqrt{2}} \times 10^{\left( \frac{SNR(dB)}{20} \right)}$$

where:

- $V_{1/f\_AMP\_PP}$  is the peak-to-peak flicker noise in  $\mu V$
  - $e_{n\_RMS}$  is the amplifier broadband noise density in  $nV/\sqrt{Hz}$
  - $f_{-3dB}$  is the 3-dB bandwidth of the charge-kickback filter
  - $N_G$  is the noise gain of the front-end circuit that is equal to 1 in a buffer configuration
- (18)
- **Settling Time.** For dc signals with fast transients that are common in a multiplexed application, the input signal must settle within an 18-bit accuracy at the device inputs during the acquisition time window. This condition is critical to maintain the overall linearity performance of the ADC. Typically, amplifier data sheets specify the output settling performance only up to 0.1% to 0.001%, which may not be sufficient for the desired 18-bit accuracy. Therefore, always verify the settling behavior of the input driver by TINA-TI SPICE simulations before selecting the amplifier.

## 8.2 Typical Application

### 8.2.1 Data Acquisition (DAQ) Circuit for Lowest Distortion and Noise Performance With Differential Input

Figure 103. Differential-Input DAQ Circuit for Lowest Distortion and Noise Using the ADS891xB

#### 8.2.1.1 Design Requirements

For this example, the design parameters are listed in [Table 21](#).

Table 21. Design Parameters

| DESIGN PARAMETER       | EXAMPLE VALUE                                       |
|------------------------|-----------------------------------------------------|
| ADC sample rate        | Maximum-specified throughput                        |
| Input signal           | 2-kHz input, 4.5-V <sub>PP</sub> fully differential |
| Noise performance, SNR | > 101-dB                                            |
| Distortion, THD        | < -120-dB                                           |
| Linearity, INL         | < ±1-LSB,                                           |
| Reference              | 4.5 V                                               |
| Power supply           | < 5.5-V analog, 3.3-V I/O                           |

#### 8.2.1.2 Detailed Design Procedure

The application circuit is illustrated in [Figure 103](#). For simplicity, power-supply decoupling capacitors are not shown in these circuit diagrams; see the [Power-Supply Recommendations](#) section for suggested guidelines.

The reference voltage of 4.5 V is generated by the high-precision, low-noise [REF5045](#) circuit. The output broadband noise of the reference is heavily filtered by a low-pass filter with a 3-dB cutoff frequency of 16 Hz.

Generally, the distortion from the input driver must be at least 10 dB less than the ADC distortion. The low-power [OPA2625](#) (a high-bandwidth, low-distortion, high-precision amplifier in an inverting gain configuration) as an input driver provides exceptional ac performance because of its extremely low-distortion and high-bandwidth specifications. The distortion resulting from variation in the common-mode signal is eliminated by using the OPA2625 in an inverting gain configuration. To exercise the complete dynamic range of the device, the common-mode voltage at the ADS891xB inputs is established at a value of 2.25 V ( $4.5\text{ V} / 2$ ) by using the noninverting pins of the OPA2625 amplifiers. In addition, the components of the charge kickback filter keep the noise from the front-end circuit low without adding distortion to the input signal.

For a complete schematic, see the [ADS8910BEVM-PDK user's guide](#) located in the [ADS8910B SAR Analog to Digital Converter Evaluation Module](#) web folder at [www.ti.com](#).

A similar circuit is used in reference design TIPD211, a step-by-step process to design a [20-Bit, 1-MSPS, 4-Ch Small Form Factor Design for Test and Measurement Applications](#) using four [ADS8900B](#) SAR ADCs, four [OPA2625](#) precision amplifiers and one [REF5050](#) precision reference.

For step-by-step design procedure, circuit schematics, bill of materials, PCB files, simulation results, and test results, refer to [TI Precision Design TIPD211, 18-Bit, 1-MSPS, 4-Ch Small Form Factor Design for Test and Measurement Applications](#) (TIDUBW7).

| Power supply           | $< 5.4\text{-V}$ analog, 3.3-V I/O                                                                              |

## 8.2.4 Detailed Design Procedure

The application circuits are shown in [Figure 108](#) and [Figure 109](#). In both applications, the input signal is processed through a high-bandwidth, low-distortion, fully-differential amplifier (FDA) designed in a gain of 1 V/V and a low-pass RC filter before going to the ADC.

The reference voltage of 4.5 V generated by the high-precision, low-noise [REF5045](#) circuit. The output broadband noise of the reference is heavily filtered by a low-pass filter with a 3-dB cutoff frequency of 16 Hz.

Generally, the distortion from the input driver must be at least 10 dB less than the ADC distortion. The distortion resulting from variation in the common-mode signal is eliminated by using the FDA in an inverting gain configuration that establishes a fixed common-mode level for the circuit. This configuration also eliminates the requirement of a rail-to-rail swing at the amplifier input. Therefore, these circuits use the low-power [THS4551](#) as an input driver that provides exceptional ac performance because of its extremely low-distortion and high bandwidth specifications. In addition, the components of the charge kickback filter keep the noise from the front-end circuit low without adding distortion to the input signal.

The circuit in [Figure 108](#) shows a fully-differential data acquisition (DAQ) block optimized for low distortion and noise using the THS4551 and ADS891xB. This front-end circuit configuration requires a differential signal at the input of the FDA and provides a differential output to drive the ADC inputs. The common-mode voltage of the input signal provided to the ADC is set by the  $V_{OCM}$  pin of the THS4551 (not shown in [Figure 108](#)). To use the complete dynamic range of the ADC,  $V_{OCM}$  can be set to  $V_{REF} / 2$  by using a simple resistive divider.

The circuit in [Figure 109](#) shows a single-ended to differential DAQ block optimized for low distortion and noise using the THS4551 and the ADS891xB. This front-end circuit configuration requires a single-ended bipolar signal at the input of the FDA and provides a fully-differential output to drive the ADC inputs. The common-mode voltage of the input signal provided to the ADC is set by the  $V_{OCM}$  pin of the THS4551 (not shown in [Figure 109](#)). To use the complete dynamic range of the ADC,  $V_{OCM}$  can be set to  $V_{REF} / 2$  by using a simple resistive divider.

## 9 Power-Supply Recommendations

The devices have two separate power supplies:  $RV_{DD}$  and  $DV_{DD}$ . The internal reference buffer and the internal LDO operate on  $RV_{DD}$ . The ADC core operates on the LDO output (available on the DECAP pins).  $DV_{DD}$  is used for the interface circuits.  $RV_{DD}$  and  $DV_{DD}$  can be independently set to any value within their permissible ranges. During normal operation, if  $RV_{DD}$  supply drops below the  $RV_{DD}$  minimum specification, ramp the  $RV_{DD}$  supply down to  $\leq 0.7$  V before power-up. During power-up,  $RV_{DD}$  must rise monotonically to the recommended minimum operating voltage.

The  $RV_{DD}$  supply voltage value defines the permissible range for the external reference voltage  $V_{REF}$  on REFIN pin as:

$$2.5 \text{ V} \leq V_{REF} \leq (RV_{DD} - 0.3) \text{ V} \quad (19)$$

Place a 10- $\mu$ F decoupling capacitor between the  $RV_{DD}$  and GND pins, and between the  $DV_{DD}$  and GND pins, as shown in [Figure 118](#). Use a minimum 1- $\mu$ F decoupling capacitor between the DECAP pins and the GND pin.

Figure 118. Power-Supply Decoupling

## 10 Layout

### 10.1 Layout Guidelines

This section provides some layout guidelines for achieving optimum performance with the ADS891xB device family.

#### 10.1.1 Signal Path

As illustrated in [Figure 119](#), the analog input signals are routed in opposite directions to the digital connections. The reference decoupling components are kept away from the switching digital signals. This arrangement prevents noise generated by digital switching activity from coupling to sensitive analog signals.

#### 10.1.2 Grounding and PCB Stack-Up

Low inductance grounding is critical for achieving optimum performance. Grounding inductance is kept below 1 nH with 15-mil grounding vias and a printed circuit board (PCB) layout design that has at least four layers. Place all critical components of the signal chain on the top layer with a solid analog ground from subsequent inner layers to minimize via length to ground.

For lowest inductance grounding, connect the GND pins of the ADS891xB (pin 11 and pin 15) directly to the device thermal pad and place at least four 8-mil grounding vias on the device thermal pad.

#### 10.1.3 Decoupling of Power Supplies

Place the decoupling capacitors on  $RV_{DD}$ , the LDO output, and  $DV_{DD}$  within 20 mil from the respective pins, and use a 15-mil via to ground from each capacitor. Avoid placing vias between any supply pin and the respective decoupling capacitor.

#### 10.1.4 Reference Decoupling

Dynamic currents are also present at the REFBUFOUT and REFM pins during the conversion phase, and excellent decoupling is required to achieve optimum performance. Place a 22- $\mu$ F, X7R-grade, ceramic capacitor with at least 10-V rating and an ESR of 1- $\Omega$  between the REFBUFOUT and the REFM pins, as illustrated in [Figure 119](#). Select 0603- or 0805-size capacitors to keep equivalent series inductance (ESL) low. Connect the REFM pins to the decoupling capacitor before a ground via.

#### 10.1.5 Differential Input Decoupling

Dynamic currents are also present at the differential analog inputs of the ADS891xB. Use C0G- or NPO-type capacitors to decouple these inputs because with these type of capacitors, capacitance stays almost constant over the full input voltage range. Lower-quality capacitors (such as X5R and X7R) have large capacitance changes over the full input-voltage range that may cause degradation in the performance of the device.

<sup>(1)</sup> **Status:** For more details on status, see our [product life cycle](#).

<sup>(2)</sup> **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

<sup>(3)</sup> **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

<sup>(4)</sup> **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

<sup>(5)</sup> **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

<sup>(6)</sup> **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "-" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## TAPE AND REEL INFORMATION

**GENERIC PACKAGE VIEW**

**VQFN - 1 mm max height**

PLASTIC QUAD FLATPACK - NO LEAD

Images above are just a representation of the package family, actual package may vary.  
Refer to the product data sheet for package details.

4204104/H

## NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.

4219016 / A 08/2017

NOTES: (continued)

4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 ([www.ti.com/lit/sluea271](http://www.ti.com/lit/sluea271)).
5. Solder mask tolerances between and around signal pads can vary based on board fabrication site.

SOLDER PASTE EXAMPLE  
BASED ON 0.125 mm THICK STENCIL

EXPOSED PAD  
78% PRINTED COVERAGE BY AREA  
SCALE: 20X

4219016 / A 08/2017

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations..
