DCP01 シリーズ、1W、1000V_{RMS} 絶縁型、非安定型 DC/DC コンバータ・モジュール

1 特長

- 1kV 絶縁 (動作上) : 1 秒間テスト
- 絶縁バリアの両側に連続的な電圧を印加: 60VDC / 42.5VAC
- UL1950 認定部品
- EN55022 Class B の EMC に準拠
- 7 ピン PDIP および 7 ピン SOP パッケージ
- 入力電圧: 5V、15V、24V
- 出力電圧: ±5V、±6.5V、±12V、±15V
- デバイス間の同期
- 過熱保護機能
- 短絡保護
- 高効率

2 アプリケーション

- 信号パス絶縁
- グランド・ループの除去
- データ・アクイジション
- 産業用制御および計測機器
- 試験用機器

3 概要

DCP01B シリーズは、1W、絶縁型、非安定型 DC/DC コンバータ・モジュールのファミリです。必要な外付け部品が最小限で、オンチップのデバイス保護が搭載されているため、DCP01B シリーズのデバイスは出力ディセーブルやスイッチング周波数の同期などの追加機能も提供できます。

これらの機能に加え、小型サイズであることから、DCP01B シリーズのデバイスは広範なアプリケーションに適しており、信号パスの絶縁が必要なアプリケーションで簡単に使用できるソリューションです。

警告：この製品の動作絶縁は、信号の絶縁のみを意図したものです。強化絶縁を必要とする安全用の絶縁回路の一部として使用してはいけません。*「機能説明」の定義を参照してください。*

7 Detailed Description

7.1 Overview

The DCP01B offers up to 1 W of isolated, unregulated output power from a 5-V, 15-V, or 24-V input source with a typical efficiency of up to 85%. This efficiency is achieved through highly integrated packaging technology and the implementation of a custom power stage and control device. The DCP01B devices are specified for operational isolation only. The circuit design uses an advanced BiCMOS and DMOS process.

7.2 Functional Block Diagrams

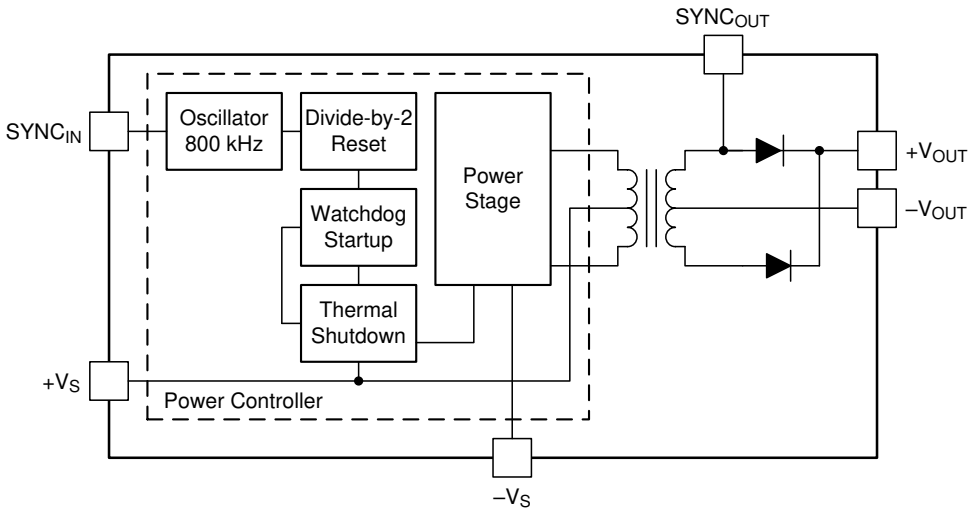

図 7-1. Single Output Device

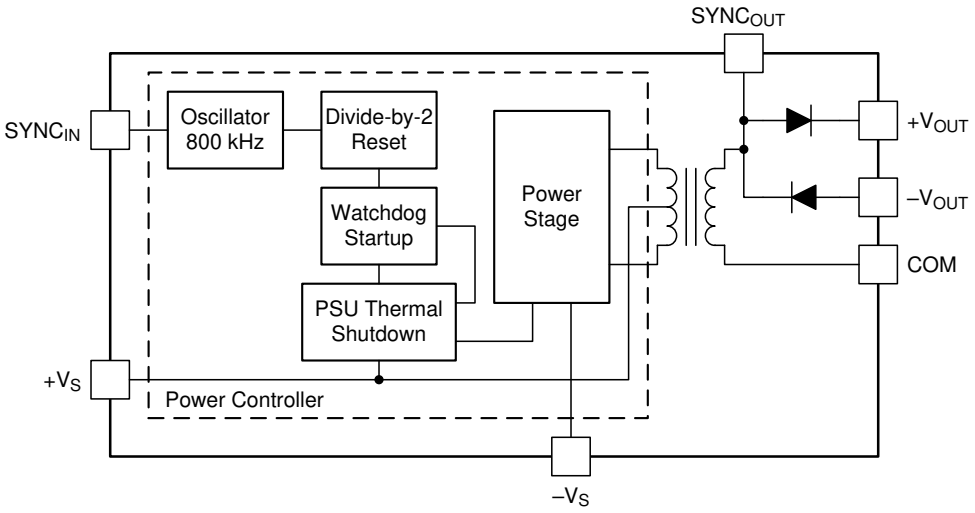

図 7-2. Dual Output Device

7.3 Feature Description

7.3.1 Isolation

Underwriters Laboratories, UL™ defines several classes of isolation that are used in modern power supplies.

Safety extra low voltage (SELV) is defined by UL (UL1950 E199929) as a secondary circuit which is so designated and protected that under normal and single fault conditions the voltage between any two accessible parts, or between an accessible part and the equipment earthing terminal for operational isolation does not exceed steady state 42.5 V peak or 60 V_{DC} for more than one second.

7.3.1.1 Operation or Functional Isolation

Operational or functional isolation is defined by the use of a high-potential (hipot) test only. Typically, this isolation is defined as the use of insulated wire in the construction of the transformer as the primary isolation barrier. The hipot one-second duration test (dielectric voltage, withstand test) is a production test used to verify that the isolation barrier is functioning. Products with operational isolation must never be used as an element in a safety-isolation system.

7.3.1.2 Basic or Enhanced Isolation

Basic or enhanced isolation is defined by specified creepage and clearance limits between the primary and secondary circuits of the power supply. Basic isolation is the use of an isolation barrier in addition to the insulated wire in the construction of the transformer. Input and output circuits must also be physically separated by specified distances.

7.3.1.3 Continuous Voltage

For a device that has no specific safety agency approvals (operational isolation), the continuous voltage that can be applied across the part in normal operation is less than 42.5 V_{RMS}, or 60 V_{DC}. Ensure that both input and output voltages maintain normal SELV limits. The isolation test voltage represents a measure of immunity to transient voltages.

WARNING

Do not use the device as an element of a safety isolation system that exceeds the SELV limit.

If the device is expected to function correctly with more than 42.5 V_{RMS} or 60 V_{DC} applied continuously across the isolation barrier, then the circuitry on both sides of the barrier must be regarded as operating at an unsafe voltage, and further isolation or insulation systems must form a barrier between these circuits and any user-accessible circuitry according to safety standard requirements.

7.3.1.4 Isolation Voltage

The terms *Hipot test*, *flash-tested*, *withstand voltage*, *proof voltage*, *dielectric withstand voltage*, and *isolation test voltage* all describe a similar idea. They describe a test voltage applied for a specified time across a component designed to provide electrical isolation to verify the integrity of that isolation. TI's DCP01B series of DC/DC converters are all 100% production tested at 1.0 kV_{AC} for one second.

7.3.1.5 Repeated High-Voltage Isolation Testing

Repeated high-voltage isolation testing of a barrier component can degrade the isolation capability, depending on materials, construction, and environment. The DCP01B series of DC/DC converters have toroidal, enameled, wire isolation transformers with no additional insulation between the primary and secondary windings. While a device can be expected to withstand several times the stated test voltage, the isolation capability depends on the wire insulation. Any material, including this enamel (typically polyurethane), is susceptible to eventual chemical degradation when subject to very-high applied voltages. Therefore, strictly limit the number of high-voltage tests and repeated high-voltage isolation testing. However, if it is absolutely required, reduce the voltage by 20% from specified test voltage with a duration limit of one second per test.

7.3.2 Power Stage

The DCP01B series of devices uses a push-pull, center-tapped topology. The DCP01B devices switch at 400 kHz (divide-by-2 from an 800-kHz oscillator).

7.3.3 Oscillator And Watchdog Circuit

The onboard, 800-kHz oscillator generates the switching frequency by a divide-by-2 circuit. The oscillator can be synchronized to other DCP01B series device circuits or an external source, and is used to minimize system noise.

A watchdog circuit checks the operation of the oscillator circuit. The oscillator can be disabled by pulling the $SYNC_{IN}$ pin low. When the $SYNC_{IN}$ pin goes low, the output pins transition into tri-state mode, which occurs within 2 µs.

7.3.4 Thermal Shutdown

The DCP01B series of devices are protected by a thermal-shutdown circuit.

If the on-chip temperature rises above 150°C, the device shuts down. Normal operation resumes as soon as the temperature falls below 150°C. While the over temperature condition continues, operation randomly cycles on and off. This cycling continues until the temperature is reduced.

7.3.5 Synchronization

When more than one DC/DC converter is needed onboard, beat frequencies and other electrical interference can be generated. This interference occurs because of the small variations in switching frequencies between the DC/DC converters.

The DCP01B series of devices overcomes this interference by allowing devices to synchronize to one another. Synchronize up to eight devices by connecting the SYNC pins of each device, taking care to minimize the capacitance of tracking. Stray capacitance (greater than 3 pF) reduces the switching frequency, or can sometimes stop the oscillator circuit. The maximum recommended voltage applied to the SYNC pin is 3.0 V.

For an application that uses more than eight synchronized devices, use an external device to drive the SYNC pins. The application report *External Synchronization of the DCP01/02 Series of DC/DC Converters* describes this configuration.

Note

During the start-up period, all synchronized devices draw maximum current from the input simultaneously. If the input voltage falls below approximately 4 V, the devices may not start up. A 2.2-µF capacitor should be connected close to each device input pin.

7.3.6 Light Load Operation (< 10%)

Operation below 10% load can cause the output voltage to increase up to double the typical output voltage. For applications that operate less than 10% of rated output current, it is recommended to add a minimum load to ensure the output voltage of the device is within the load regulation range. For example, connect a 250-Ω pre-load resistor to meet the 10% minimum load condition for the DCP010505BP.

7.3.7 Load Regulation (10% to 100%)

The load regulation of the DCP01B series of devices is specified at 10% to 100% load. Placing a minimum 10% load will ensure the output voltage is within the range specified in *セクション 6.5*. For more information regarding operation below 10% load, see *セクション 7.3.6*.

7.3.8 Construction

The basic construction of the DCP01B series of devices is the same as standard integrated circuits. The molded package contains no substrate. The DCP01B series of devices are constructed using an IC, rectifier diodes, and a wound magnetic toroid on a lead frame. Because the package contains no solder, the devices do not require any special printed circuit board (PCB) assembly processing. This architecture results in an isolated DC/DC converter with inherently high reliability.

7.3.9 Thermal Management

Due to the high power density of these devices, it is advisable to provide ground planes on the input and output rails.

7.3.10 Power-Up Characteristics

The DCP01B series of devices do not include a soft-start feature. Therefore, a high in-rush current during power up is expected. Refer to the DCPA1 series of devices for a 1-W, isolated, unregulated DC/DC converter module with soft start included. 図 7-3 shows the typical start-up waveform for a DCP010505BP, operating from a 5-V input with no load on the output. 図 7-4 shows the start-up waveform for a DCP010505BP starting up into a 10% load. 図 7-5 shows the start-up waveform starting up into a full (100%) load.

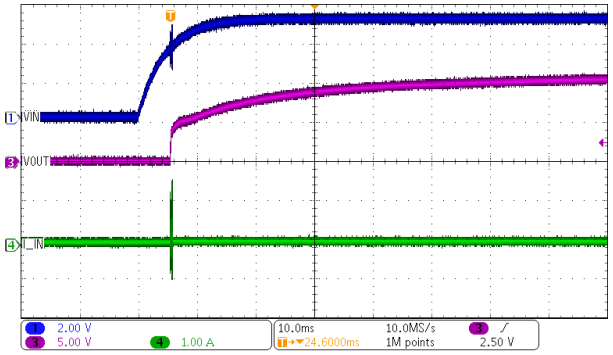

図 7-3. DCP010505BP Start-Up at No Load

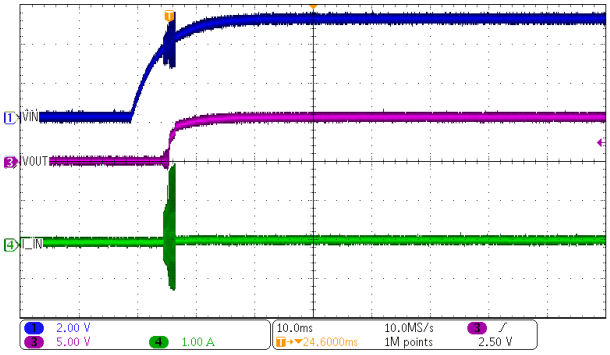

図 7-4. DCP010505BP Start-Up at 10% Load

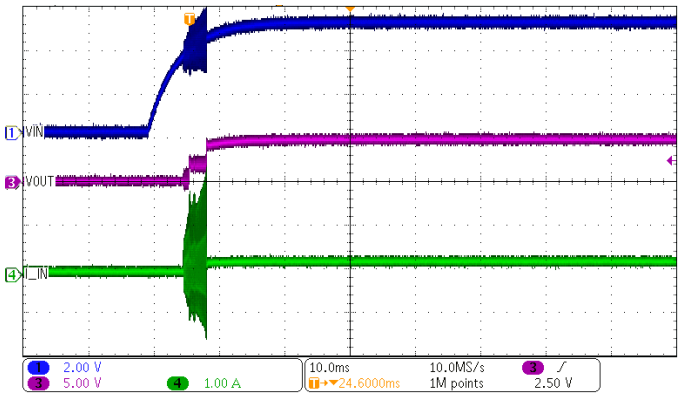

図 7-5. DCP010505BP Start-Up at 100% Load

7.4 Device Functional Modes

7.4.1 Disable and Enable ($SYNC_{IN}$ Pin)

Each of the DCP01B series devices can be disabled or enabled by driving the $SYNC_{IN}$ pin using an open-drain CMOS gate. If the $SYNC_{IN}$ pin is pulled low, the DCP01B becomes disabled. The disable time depends upon the external loading. The internal disable function is implemented within 2 µs. Removal of the pulldown causes the DCP01B to be enabled.

Capacitive loading on the $SYNC_{IN}$ pin must be minimized (≤ 3 pF) to prevent a reduction in the oscillator frequency. The application report *External Synchronization of the DCP01/02 Series of DC/DC Converters* describes disable and enable control circuitry.

7.4.2 Decoupling

7.4.2.1 Ripple Reduction

The high switching frequency of 400 kHz allows simple filtering. To reduce ripple, it is recommended that a minimum of 1-µF capacitor be used on the $+V_{OUT}$ pin. For dual output devices, decouple both of the outputs to the COM pin. The required 2.2-µF, low ESR ceramic input capacitor also helps reduce ripple and noise, (24-V input voltage versions require only 0.47 µF of input capacitance). See application report *DC-to-DC Converter Noise Reduction*.

7.4.2.2 Connecting the DCP01B in Series

Multiple DCP01B isolated 1-W DC/DC converters can be connected in series to provide non-standard voltage rails. This configuration is possible by using the floating outputs provided by the galvanic isolation of the DCP01.

Connect the $+V_{OUT}$ from one DCP01B to the $–V_{OUT}$ of another (see 図 7-6). If the $SYNC_{IN}$ pins are tied together, the self-synchronization feature of the DCP01B prevents beat frequencies on the voltage rails. The synchronization feature of the DCP01B allows easy series connection without external filtering, thus minimizing cost.

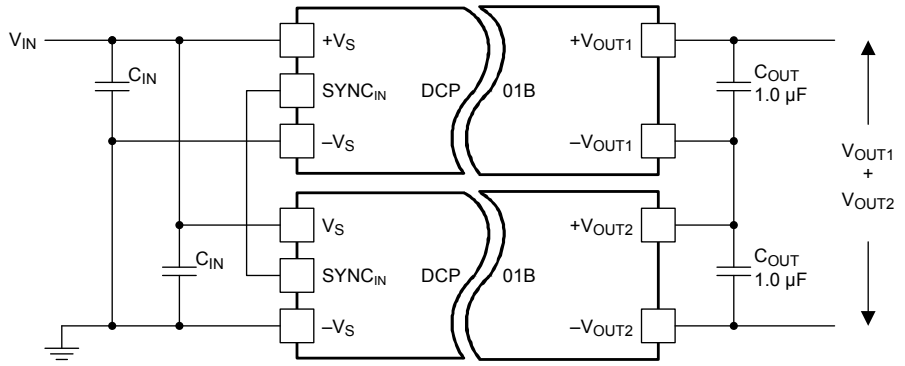

図 7-6. Multiple DCP01B Devices Connected in Series

The outputs of a dual-output DCP01B can also be connected in series to provide two times the magnitude of $+V_{OUT}$, as shown in 図 7-7. For example, connect a dual-output, 15-V, DCP012415DB device to provide a 30-V rail.

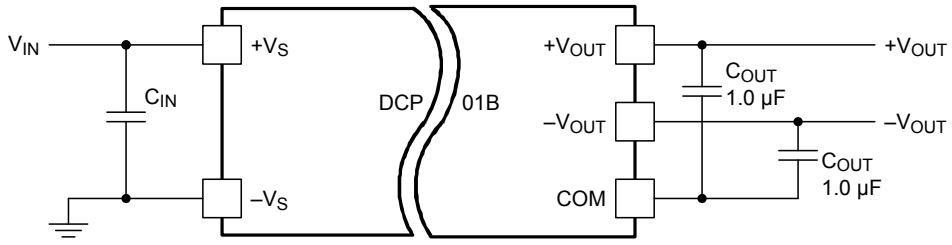

図 7-7. Dual Output Devices Connected in Series

7.4.2.3 Connecting the DCP01B in Parallel

If the output power from one DCP01B is not sufficient, it is possible to parallel the outputs of multiple DCP01Bs, as shown in 図 7-8 (applies to single output devices only). The synchronization feature allows easy synchronization to prevent power-rail beat frequencies at no additional filtering cost.

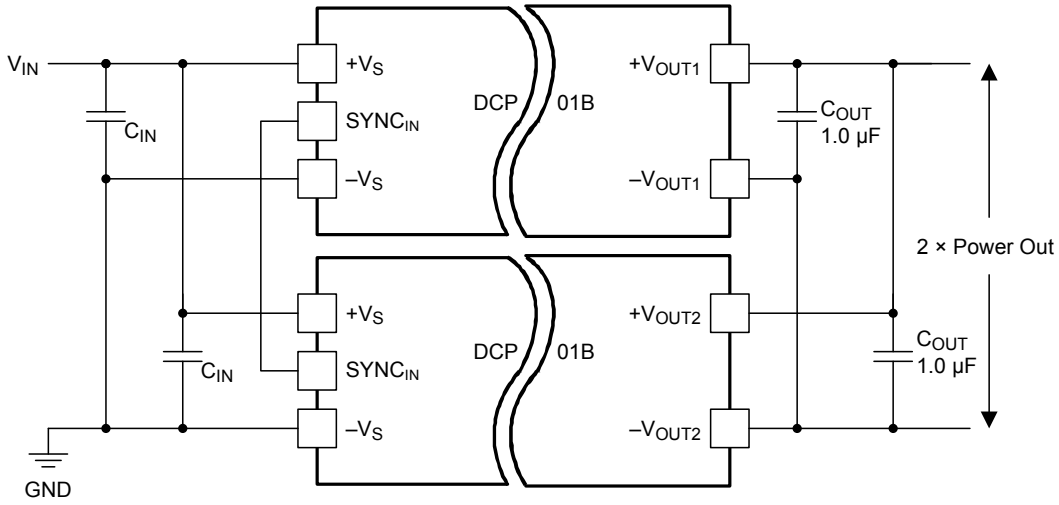

図 7-8. Multiple DCP01B Devices Connected in Parallel

8 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.2 Typical Application

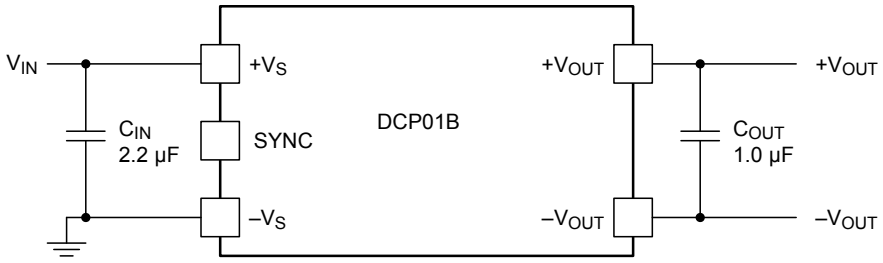

図 8-1. Typical DCP010505 Application

8.2.1 Design Requirements

For this design example, use the parameters listed in 表 8-1 and follow the design procedures shown in the *セクション 8.2.2*.

表 8-1. Design Example Parameters

PARAMETER		VALUE	UNIT
$V_{(+VS)}$	Input voltage	5	V
$V_{(+VOUT)}$	Output voltage	5	V

8.2.2 Detailed Design Procedure

8.2.2.1 Input Capacitor

For all 5-V and 15-V input voltage designs, select a 2.2-µF low-ESR ceramic input capacitor to ensure a good startup performance. 24-V input applications require only 0.47-µF of input capacitance.

8.2.2.2 Output Capacitor

For any DCP01B design, select a 1.0-µF low-ESR ceramic output capacitor to reduce output ripple.

8.2.2.3 $SYNC_{IN}$ Pin

In a stand-alone application, leave the $SYNC_{IN}$ pin floating.

8.2.4 PCB Design

The copper losses (resistance and inductance) can be minimized by the use of mutual ground and power planes (tracks) where possible. If that is not possible, use wide tracks to reduce the losses. If several devices are being powered from a common power source, a star-connected system for the track must be deployed. Do not connect the devices in series, because that type of connection cascades the resistive losses. The position of the decoupling capacitors is important. They must be as close to the devices as possible in order to reduce losses. See *セクション 10* for more details.

8.2.5 Decoupling Ceramic Capacitors

All capacitors have losses because of internal equivalent series resistance (ESR), and to a lesser degree, equivalent series inductance (ESL). Values for ESL are not always easy to obtain. However, some manufacturers provide graphs of frequency versus capacitor impedance. These graphs typically show the capacitor impedance falling as frequency is increased (as shown in 図 8-4). In 図 8-4, X_C is the reactance due to the capacitance, X_L is the reactance due to the ESL, and f_0 is the resonant frequency. As the frequency increases, the impedance stops decreasing and begins to rise. The point of minimum impedance indicates the resonant frequency of the capacitor. This frequency is where the components of capacitance and inductance reactance are of equal magnitude. Beyond this point, the capacitor is not effective as a capacitor.

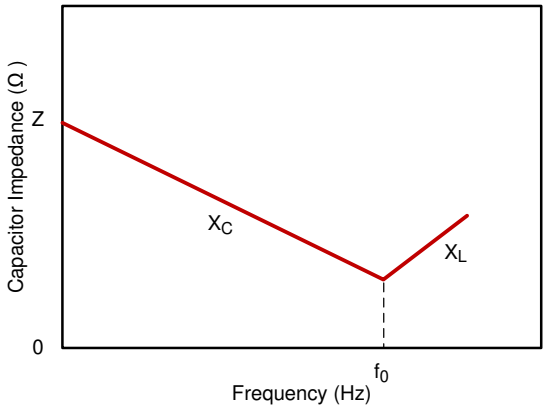

図 8-4. Capacitor Impedance versus Frequency

However, there is a 180° phase difference resulting in cancellation of the imaginary component. The resulting effect is that the impedance at the resonant point is the real part of the complex impedance, namely, the value of the ESR. The output capacitor's resonant frequency must be higher than the default switching frequency (800 kHz) of the device to properly decouple noise at and below the switching frequency.

The effect of the ESR is to cause a voltage drop within the capacitor. The value of this voltage drop is simply the product of the ESR and the transient load current, as shown in 式 1.

$$V_{IN} = V_{PK} – (ESR \times I_{TR}) \quad (1)$$

where

- V_{IN} is the voltage at the device input
- V_{PK} is the maximum value of the voltage on the capacitor during charge
- I_{TR} is the transient load current

The other factor that affects the performance is the value of the capacitance. However, for the input and the full wave outputs (single-output voltage devices), ESR is the dominant factor.

8.2.6 Input Capacitor and the Effects of ESR

If the input decoupling capacitor is not ceramic (and has an ESR greater than 20 mΩ), then at the instant the power transistors switch on, the voltage at the input pins falls momentarily. If the voltage falls below approximately 4 V, the device detects an undervoltage condition and switches the internal drive circuits to a momentary off state. This detection is carried out as a precaution against a genuine low input voltage condition that could slow down or even stop the internal circuits from operating correctly. A slow-down or stoppage results in the drive transistors being turned on too long, causing saturation of the transformer and destruction of the device.

Following detection of a low input voltage condition, the device switches off the internal drive circuits until the input voltage returns to a safe value, at which time the device tries to restart. If the input capacitor is still unable to maintain the input voltage, shutdown recurs. This process repeats until the input capacitor charges sufficiently to start the device correctly.

Normal start-up should occur in approximately 1 ms after power is applied to the device. If a considerably longer start-up duration time is encountered, it is likely that either (or both) the input supply or the capacitors are not performing adequately.

For 5-V to 15-V input devices, a 2.2-µF, low-ESR ceramic capacitor ensures good startup performance. For 24-V input voltage devices, 0.47-µF ceramic capacitors are recommended. Tantalum capacitors are not recommended, since most do not have low-ESR values and will degrade performance. If tantalum capacitors must be used, close attention must be paid to both the ESR and voltage as derated by the vendor.

Note

During the start-up period, these devices may draw maximum current from the input supply. If the input voltage falls below approximately 4 V, the devices may not start up. Connect a 2.2-µF ceramic capacitor close to the input pins.

8.2.7 Ripple and Noise

A good quality, low-ESR ceramic capacitor placed as close as practical across the input reduces reflected ripple and ensures a smooth start-up.

A good quality, low-ESR ceramic capacitor placed as close as practical across the rectifier output terminal and output ground gives the best ripple and noise performance. See application report *DC-to-DC Converter Noise Reduction* for more information on noise rejection.

8.2.7.1 Output Ripple Calculation Example

The following example shows that increasing the capacitance has a much smaller effect on the output ripple voltage than does reducing the value of the ESR for the filter capacitor.

To calculate the output ripple for a DCP010505 device:

- V_{OUT} = 5 V
- I_{OUT} = 0.2 A

- At full output power, the load resistor is 25 Ω
- Ceramic output capacitor of 1 µF, ESR of 0.1 Ω
- Capacitor discharge time 1% of 800 kHz (ripple frequency)

t_{DIS} = 0.0125 µs

$\tau = C \times R_{LOAD}$

$\tau = 1 \times 10^{-6} \times 12.5 = 12.5$ µs

$V_{DIS} = V_O(1 – EXP(–t_{DIS} / \tau))$

V_{DIS} = 5 mV

By contrast, the voltage dropped because of ESR:

$V_{ESR} = I_{LOAD} \times ESR$

V_{ESR} = 20 mV

Ripple voltage = 25 mV

8.2.8 Dual DCP01B Output Voltage

The voltage output for dual DCP01B devices is half wave rectified; therefore, the discharge time is 1.25 µs. Repeating the above calculations using the 100% load resistance of 50 Ω (0.1 A per output), the results are:

τ = 25 µs

t_{DIS} = 1.25 µs

V_{DIS} = 244 mV

V_{ESR} = 10 mV

Ripple Voltage = 133 mV

This time, it is the capacitor discharging that contributes to the largest component of ripple. Changing the output filter to 10 µF, and repeating the calculations, the result is:

Ripple voltage = 25 mV

This value is composed of almost equal components.

The previous calculations are offered as a guideline only. Capacitor parameters usually have large tolerances and can be susceptible to environmental conditions.

8.2.9 Optimizing Performance

Optimum performance can only be achieved if the device is correctly supported. The very nature of a switching converter requires power to be instantly available when it switches on. If the converter has DMOS switching transistors, the fast edges will create a high current demand on the input supply. This transient load placed on the input is supplied by the external input decoupling capacitor, thus maintaining the input voltage. Therefore, the input supply does not see this transient (this is an analogy to high-speed digital circuits). The positioning of the capacitor is critical and must be placed as close as possible to the input pins and connected via a low-impedance path.

The optimum performance primarily depends on two factors:

- Connection of the input and output circuits for minimal loss.
- The ability of the decoupling capacitors to maintain the input and output voltages at a constant level.

9 Power Supply Recommendations

The DCP01B is a switching power supply, and as such can place high peak current demands on the input supply. To avoid the supply falling momentarily during the fast switching pulses, ground and power planes must be used to connect the power to the input of DCP01 device. If this connection is not possible, then the supplies must be connected in a star formation with the traces made as wide as possible.

10 Layout

10.1 Layout Guidelines

Due to the high power density of these devices, provide ground planes on the input and output rails.

図 10-1 and 図 10-2 show the schematic for the two DIP through-hole packages, and two SOP surface-mount packages for the DCP family of products which include DCP01B, DCP02, DCV01, DCR01, and DCR02. 図 10-3 and 図 10-4 illustrate a printed circuit board (PCB) layout for the schematics.

Including input power and ground planes provides a low-impedance path for the input power. For the output, the COM signal connects via a ground plane, while the connections for the positive and negative voltage outputs conduct via wide traces in order to minimize losses.

The output should be taken from the device using ground and power planes, thereby ensuring minimum losses.

The location of the decoupling capacitors in close proximity to their respective pins ensures low losses due to the effects of stray inductance, thus improving the ripple performance. This location is of particular importance to the input decoupling capacitor, because this capacitor supplies the transient current associated with the fast switching waveforms of the power drive circuits.

Allow the unused SYNC pin, to remain configured as a floating pad. It is advisable to place a guard ring (connected to input ground) or annulus connected around this pin to avoid any noise pick up. When connecting a SYNC pin to one or more SYNC design the linking trace to be short and narrow to avoid stray capacitance. Ensure that no other trace is in close proximity to this trace SYNC trace to decrease the stray capacitance on this pin. The stray capacitance affects the performance of the oscillator.

11.7 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

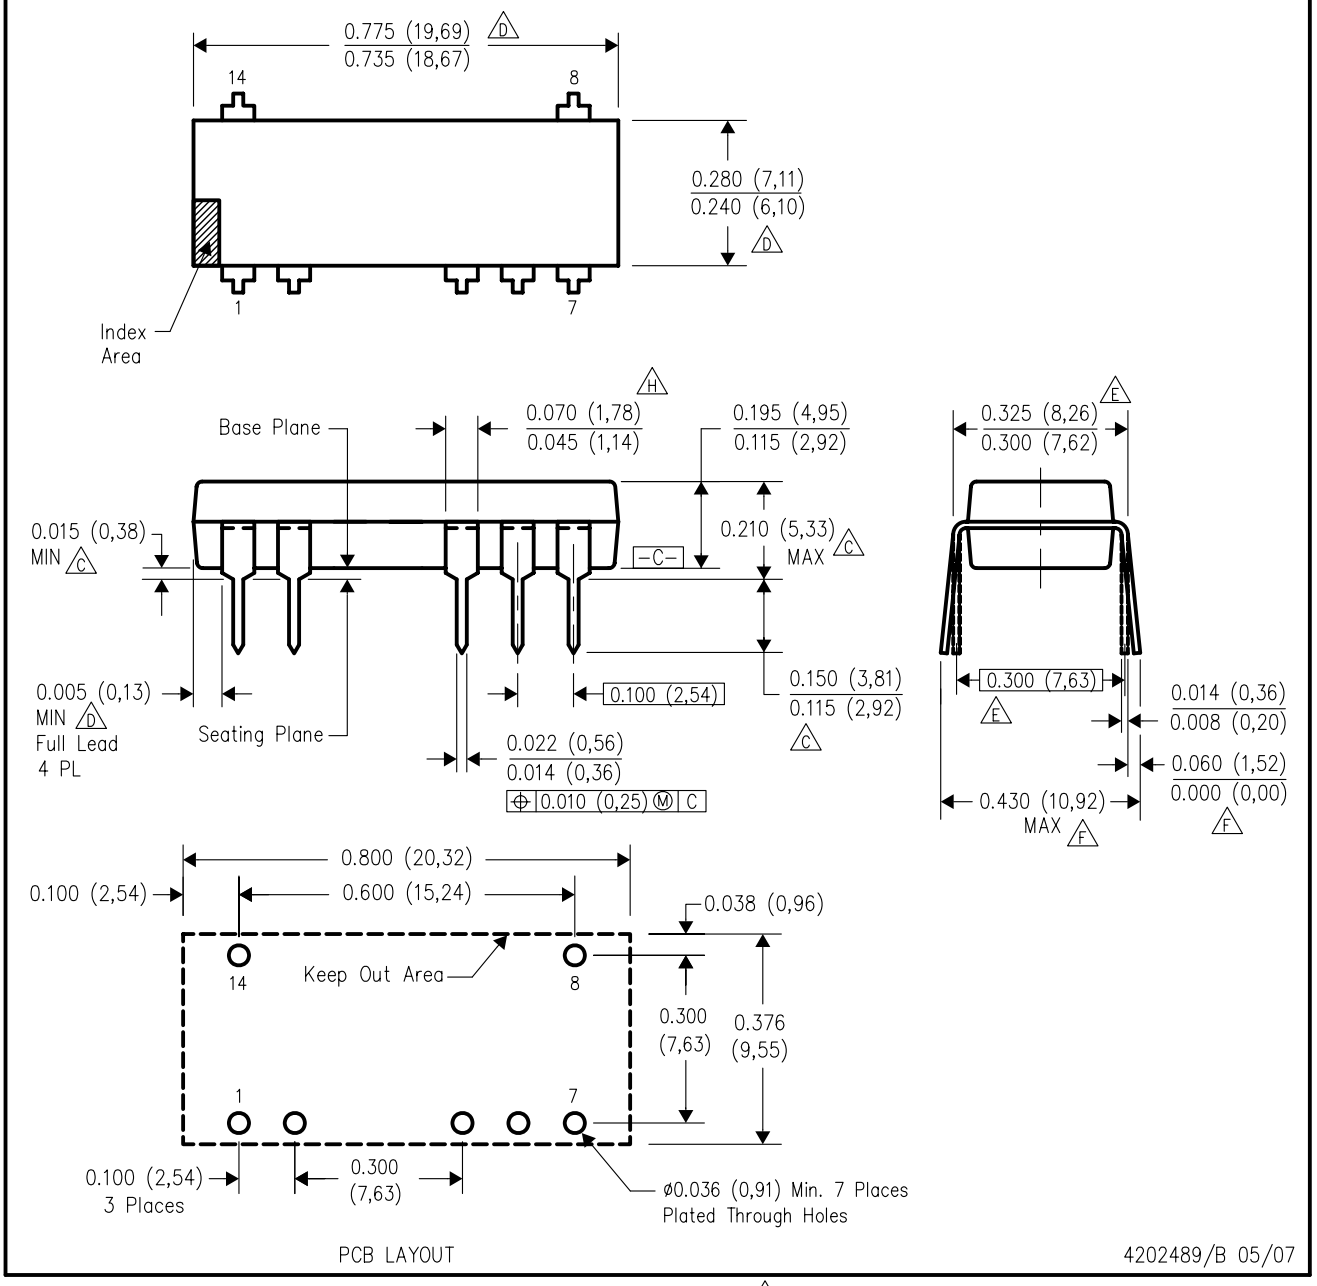
NVA (R–PDIP–T7/14) PLASTIC DUAL–IN–LINE



PCB LAYOUT

4202489/B 05/07

NOTES:
- A. All linear dimensions are in inches (millimeters).
- B. This drawing is subject to change without notice.
- C. Dimensions are measured with the package seated in JEDEC seating plane gauge GS–3.
- D. Dimensions do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.010 (0,25).
- E. Dimensions measured with the leads constrained to be perpendicular to Datum C.
- F. Dimensions are measured at the lead tips with the leads unconstrained.
- G. Pointed or rounded lead tips are preferred to ease insertion.
- H. Lead shoulder maximum dimension does not include dambar protrusions. Dambar protrusions shall not exceed 0.010 (0,25).
- I. Distance between leads including dambar protrusions to be 0.005 (0,13) minimum.
- J. A visual index feature must be located within the cross–hatched area.
- K. For automatic insertion, any raised irregularity on the top surface (step, mesa, etc.) shall be symmetrical about the lateral and longitudinal package centerlines.
- L. Falls within JEDEC MS–001–AA.
