

LM5109A、高電圧、1Aピーク、ハーフブリッジ・ゲート・ドライバ

1 特長

- ハイサイドとローサイド両方のNチャネル MOSFETを駆動
- ピーク出力電流1A（1.0Aシンク/1.0Aソース）
- 独立したTTL互換入力
- ブートストラップ電源電圧：108V DC
- 高速伝搬時間（標準30ns）
- 15nsの立ち上がり/立ち下がり時間で1000pFの負荷を駆動
- 優れた伝搬遅延マッチング（標準2ns）
- 電源レールの低電圧誤動作防止
- 低消費電力
- ISL6700とピン・コンパチブル
- 業界標準のSOIC-8および放熱特性の優れた WSON-8パッケージ

2 アプリケーション

- 電流供給プッシュプル・コンバータ
- ハーフ/フルブリッジのパワー・コンバータ
- ソリッド・ステート・モーター・ドライブ
- 2スイッチのフォワード・パワー・コンバータ

3 概要

LM5109Aは、同期降圧型またはハーフブリッジの構成においてハイサイドとローサイド両方のNチャネルMOSFETを駆動するよう設計された、コスト効率の優れた高電圧ゲート・ドライバです。フローティング・ハイサイド・ドライバは、最大90Vのレール電圧で動作できます。各出力は、TTL互換の入力スレッショルドによって独立に制御されます。堅牢なレベル・シフト技術により、消費電力を抑えながら高速で動作し、制御入力ロジックからハイサイド・ゲート・ドライバへのクリーンなレベル遷移を実現します。ローサイドとハイサイド両方の電源レールに低電圧誤動作防止機能が搭載されています。このデバイスは、SOICパッケージ、および熱特性を強化したWSONパッケージで供給されます。

5 Pin Configuration and Functions

Pin Functions

Pin #		NAME	DESCRIPTION	APPLICATION INFORMATION
SOIC	WSON ⁽¹⁾			
1	1	V _{DD}	Positive gate drive supply	Locally decouple to V _{SS} using low ESR/ESL capacitor located as close to IC as possible.
2	2	HI	High side control input	The HI input is compatible with TTL input thresholds. Unused HI input should be tied to ground and not left open
3	3	LI	Low side control input	The LI input is compatible with TTL input thresholds. Unused LI input should be tied to ground and not left open.
4	4	V _{SS}	Ground reference	All signals are referenced to this ground.
5	5	LO	Low side gate driver output	Connect to the gate of the low-side N- MOS device.
6	6	HS	High side source connection	Connect to the negative terminal of the bootstrap capacitor and to the source of the high-side N-MOS device.
7	7	HO	High side gate driver output	Connect to the gate of the high-side N-MOS device.
8	8	HB	High side gate driver positive supply rail	Connect the positive terminal of the bootstrap capacitor to HB and the negative terminal of the bootstrap capacitor to HS. The bootstrap capacitor should be placed as close to IC as possible.

- (1) For WSON package it is recommended that the exposed pad on the bottom of the package be soldered to ground plane on the PCB and the ground plane should extend out from underneath the package to improve heat dissipation.

6 Specifications

6.1 Absolute Maximum Ratings

See ⁽¹⁾⁽²⁾

	MIN	MAX	UNIT
V _{DD} to V _{SS}	–0.3	18	V
HB to HS	–0.3	18	V
LI or HI to V _{SS}	–0.3	V _{DD} + 0.3	V
LO to V _{SS}	–0.3	V _{DD} + 0.3	V
HO to V _{SS}	V _{HS} – 0.3	V _{HB} + 0.3	V
HS to V _{SS} ⁽³⁾	–5	90	V
HB to V _{SS}		108	V
Junction Temperature	–40	150	°C
Storage Temperature Range	–55	150	°C

- (1) Absolute Maximum Ratings indicate limits beyond which damage to the component may occur. Operating Ratings are conditions under which operation of the device is specified. Operating Ratings do not imply performance limits. For performance limits and associated test conditions, see the [Electrical Characteristics](#).
- (2) If Military/Aerospace specified devices are required, please contact the Texas Instruments Sales Office/Distributors for availability and specifications.
- (3) In the application the HS node is clamped by the body diode of the external lower N-MOSFET, therefore the HS voltage will generally not exceed –1V. However in some applications, board resistance and inductance may result in the HS node exceeding this stated voltage transiently. If negative transients occur on HS, the HS voltage must never be more negative than V_{DD} – 15V. For example, if V_{DD} = 10V, the negative transients at HS must not exceed –5V.

LM5109A

JAJSC52C – APRIL 2006 – REVISED SEPTEMBER 2016

6.2 ESD Ratings

		VALUE	UNIT
V_{ESD}	Electrostatic discharge Human-body model (HBM) ⁽¹⁾	±1500	V

(1) The human body model is a 100 pF capacitor discharged through a 1.5kΩ resistor into each pin.

6.3 Recommended Operating Conditions

	MIN	NOM	MAX	UNIT
V_{DD}	8		14	V
HS ⁽¹⁾	–1		90	V
HB	$V_{\text{HS}} + 8$		$V_{\text{HS}} + 14$	V
HS Slew Rate			< 50	V/ns
Junction Temperature	–40		125	°C

(1) In the application the HS node is clamped by the body diode of the external lower N-MOSFET, therefore the HS voltage will generally not exceed –1V. However in some applications, board resistance and inductance may result in the HS node exceeding this stated voltage transiently. If negative transients occur on HS, the HS voltage must never be more negative than $V_{\text{DD}} - 15\text{V}$. For example, if $V_{\text{DD}} = 10\text{V}$, the negative transients at HS must not exceed –5V.

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾		LM5109A		UNIT
		D (SOIC)	NGT (WSON)	
		8 PINS	8 PINS	
$R_{\theta\text{JA}}$	Junction-to-ambient thermal resistance	117.6	42.3	°C/W
$R_{\theta\text{JC(top)}}$	Junction-to-case (top) thermal resistance	64.9	34	°C/W
$R_{\theta\text{JB}}$	Junction-to-board thermal resistance	58.1	19.3	°C/W
Ψ_{JT}	Junction-to-top characterization parameter	17.4	0.4	°C/W
Ψ_{JB}	Junction-to-board characterization parameter	57.6	19.5	°C/W
$R_{\theta\text{JC(bot)}}$	Junction-to-case (bottom) thermal resistance	–	8.1	°C/W

(1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

6.5 Electrical Characteristics

Unless otherwise specified, $V_{\text{DD}} = V_{\text{HB}} = 12\text{V}$, $V_{\text{SS}} = V_{\text{HS}} = 0\text{V}$, No Load on LO or HO ⁽¹⁾. Typical limits are for $T_{\text{J}} = 25^{\circ}\text{C}$, and minimum and maximum limits apply over the operating junction temperature range (–40°C to 125°C).

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
SUPPLY CURRENTS						
I_{DD}	V_{DD} quiescent current	LI = HI = 0V		0.3	0.6	mA
I_{DDO}	V_{DD} operating current	f = 500 kHz		1.8	2.9	mA
I_{HB}	Total HB quiescent current	LI = HI = 0V		0.06	0.2	mA
I_{HBO}	Total HB operating current	f = 500 kHz		1.4	2.8	mA
I_{HBS}	HB to V_{SS} current, quiescent	$V_{\text{HS}} = V_{\text{HB}} = 90\text{V}$		0.1	10	μA
I_{HBSO}	HB to V_{SS} current, operating	f = 500 kHz		0.5		mA
INPUT PINS LI and HI						
V_{IL}	Low-level input voltage threshold		0.8	1.8		V
V_{IH}	High-level input voltage threshold			1.8	2.2	V
R_{I}	Input pulldown resistance		100	200	500	kΩ
UNDER-VOLTAGE PROTECTION						
V_{DDR}	V_{DD} rising threshold	$V_{\text{DDR}} = V_{\text{DD}} - V_{\text{SS}}$	6.0	6.7	7.4	V
V_{DDH}	V_{DD} threshold hysteresis			0.5		V
V_{HBR}	HB rising threshold	$V_{\text{HBR}} = V_{\text{HB}} - V_{\text{HS}}$	5.7	6.6	7.1	V

(1) Minimum and maximum limits are 100% production tested at 25°C. Limits over the operating temperature range are specified through correlation using Statistical Quality Control (SQC) methods. Limits are used to calculate Average Outgoing Quality Level (AOQL).

Electrical Characteristics (continued)

Unless otherwise specified, $V_{DD} = V_{HB} = 12V$, $V_{SS} = V_{HS} = 0V$, No Load on LO or HO⁽¹⁾. Typical limits are for $T_J = 25^\circ C$, and minimum and maximum limits apply over the operating junction temperature range ($-40^\circ C$ to $125^\circ C$).

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
V_{HBH}	HB threshold hysteresis			0.4		V
LO GATE DRIVER						
V_{OLL}	Low-level output voltage	$I_{LO} = 100\text{ mA}$, $V_{OHL} = V_{LO} - V_{SS}$		0.38	0.65	V
V_{OHL}	High-level output voltage	$I_{LO} = -100\text{ mA}$, $V_{OHL} = V_{DD} - V_{LO}$		0.72	1.20	V
I_{OHL}	Peak pullup current	$V_{LO} = 0V$		1.0		A
I_{OLL}	Peak pulldown current	$V_{LO} = 12V$		1.0		A

7 Detailed Description

7.1 Overview

The LM5109A is a cost-effective, high-voltage gate driver designed to drive both the high-side and the low-side N-channel FETs in a synchronous buck or a half-bridge configuration. The outputs are independently controlled with TTL compatible input thresholds. The floating high-side driver is capable of working with HB voltage up to 108 V. An external high-voltage diode must be provided to charge high-side gate drive bootstrap capacitor. A robust level shifter operates at high speed while consuming low power and providing clean level transitions from the control logic to the high-side gate driver. Undervoltage lockout (UVLO) is provided on both the low-side and the high-side power rails.

7.2 Functional Block Diagram

Copyright © 2016, Texas Instruments Incorporated

7.3 Feature Description

7.3.1 Start-Up and UVLO

Both top and bottom drivers include UVLO protection circuitry which monitors the supply voltage (V_{DD}) and bootstrap capacitor voltage (V_{HB-HS}) independently. The UVLO circuit inhibits the output until sufficient supply voltage is available to turn on the external MOSFETs, and the built-in UVLO hysteresis prevents chattering during supply voltage variations. When the supply voltage is applied to the VDD pin of the LM5109A, the top and bottom gates are held low until V_{DD} exceeds the UVLO threshold, typically about 6.7 V. Any UVLO condition on the bootstrap capacitor (V_{HB-HS}) will only disable the high-side output (HO).

7.3.2 Level Shift

The level shift circuit is the interface from the high-side input to the high-side driver stage which is referenced to the switch node (HS). The level shift allows control of the HO output which is referenced to the HS pin and provides excellent delay matching with the low-side driver.

Feature Description (continued)

7.3.3 Output Stages

The output stages are the interface to the power MOSFETs in the power train. High slew rate, low resistance, and high-peak current capability of both outputs allow for efficient switching of the power MOSFETs. The low-side output stage is referenced to VSS and the high-side is referenced to HS.

7.4 Device Functional Modes

The device operates in normal mode and UVLO mode. See [Start-Up and UVLO](#) for more information on UVLO operation mode. In normal mode when the V_{DD} and V_{HB-HS} are above UVLO threshold, the output stage is dependent on the states of the HI and LI pins. The output HO and LO will be low if input state is floating.

Table 1. INPUT and OUTPUT Logic Table

HI	LI	HO ⁽¹⁾	LO ⁽²⁾
L	L	L	L
L	H	L	H
H	L	H	L
H	H	H	H
Floating	Floating	L	L

(1) HO is measured with respect to the HS.

(2) LO is measured with respect to the VSS.

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

To operate power MOSFETs at high switching frequencies and to reduce associated switching losses, a powerful gate driver is employed between the PWM output of controller and the gates of the power semiconductor devices. Also, gate drivers are indispensable when it is impossible for the PWM controller to directly drive the gates of the switching devices. With the advent of digital power, this situation is often encountered because the PWM signal from the digital controller is often a 3.3-V logic signal which cannot effectively turn on a power switch. Level shift circuit is needed to boost the 3.3-V signal to the gate-drive voltage (such as 12 V) to fully turn on the power device and minimize conduction losses. Traditional buffer drive circuits based on NPN and PNP bipolar transistors in totem-pole arrangement prove inadequate with digital power because they lack level-shifting capability. Gate drivers effectively combine both the level-shifting and buffer-drive functions. Gate drivers also find other needs such as minimizing the effect of high-frequency switching noise (by placing the high-current driver IC physically close to the power switch), driving gate-drive transformers and controlling floating power-device gates, reducing power dissipation and thermal stress in controllers by moving gate charge power losses from the controller into the driver.

The LM5109A is the high-voltage gate drivers designed to drive both the high-side and low-side N-channel MOSFETs in a half-bridge configuration, full-bridge configuration, or in a synchronous buck circuit. The floating high-side driver is capable of operating with supply voltages up to 90 V. This allows for N-channel MOSFETs control in half-bridge, full-bridge, push-pull, two-switch forward and active clamp topologies. The outputs are independently controlled. Each channel is controlled by its respective input pins (HI and LI), allowing full and independent flexibility to control ON and OFF-time of the output.

8.1.1 HS Transient Voltages Below Ground

The HS node will always be clamped by the body diode of the lower external FET. In some situations, board resistances and inductances can cause the HS node to transiently swing several volts below ground. The HS node can swing below ground provided:

1. HS must always be at a lower potential than HO. Pulling HO more than -0.3V below HS can activate parasitic transistors resulting in excessive current flow from the HB supply, possibly resulting in damage to the IC. The same relationship is true with LO and VSS. If necessary, a Schottky diode can be placed externally between HO and HS or LO and GND to protect the IC from this type of transient. The diode must be placed as close to the IC pins as possible in order to be effective.
2. HB to HS operating voltage should be 15V or less. Hence, if the HS pin transient voltage is -5V , VDD should be ideally limited to 10V to keep HB to HS below 15V.
3. Low ESR bypass capacitors from HB to HS and from VDD to VSS are essential for proper operation. The capacitor should be located at the leads of the IC to minimize series inductance. The peak currents from LO and HO can be quite large. Any series inductances with the bypass capacitor will cause voltage ringing at the leads of the IC which must be avoided for reliable operation.

8.2 Typical Application

Figure 14. LM5109A Driving MOSFETs in a Half-Bridge Converter

8.2.1 Design Requirements

Table 2 lists the design parameters of the LM5109A.

Table 2. Design Example

PARAMETER	VALUE
Gate Driver	LM5109A
MOSFET	CSD19534KCS
V_{DD}	10 V
Q_G	17 nC
f_{SW}	500 kHz

8.2.2 Detailed Design Procedure

8.2.2.1 Select Bootstrap and VDD Capacitor

The bootstrap capacitor must maintain the V_{HB-HS} voltage above the UVLO threshold for normal operation. Calculate the maximum allowable drop across the bootstrap capacitor with Equation 1.

$$\Delta V_{HB} = V_{DD} - V_{DH} - V_{HBL} = 10 \text{ V} - 1 \text{ V} - 6.7 \text{ V} = 2.3 \text{ V}$$

where

- V_{DD} = Supply voltage of the gate drive IC
- V_{DH} = Bootstrap diode forward voltage drop
- $V_{HBL} = V_{HBRmax} - V_{HBH}$, HB falling threshold

(1)

Then, the total charge needed per switching cycle is estimated by Equation 2.

$$Q_{Total} = Q_G + I_{HBS} \times \frac{D_{Max}}{f_{SW}} + \frac{I_{HB}}{f_{SW}} = 17 \text{ nC} + 10 \mu\text{A} \times \frac{0.95}{500 \text{ kHz}} + \frac{0.2 \text{ mA}}{500 \text{ kHz}} = 17.5 \text{ nC}$$

where

- Q_G = Total MOSFET gate charge

- I_{HBS} = HB to VSS Leakage current
 - D_{Max} = Converter maximum duty cycle
 - I_{HB} = HB Quiescent current
- (2)

Therefore, the minimum C_{Boot} must be:

$$C_{Boot} = \frac{Q_{Total}}{\Delta V_{HB}} = \frac{17.5 \text{ nC}}{2.3 \text{ V}} = 7.6 \text{ nF}$$
(3)

In practice, the value of the C_{Boot} capacitor must be greater than calculated to allow for situations where the power stage may skip pulse due to load transients. TI recommends having enough margins and place the bootstrap capacitor as close to the HB and HS pins as possible.

$$C_{Boot} = 100 \text{ nF}$$
(4)

As a general rule the local V_{DD} bypass capacitor must be 10 times greater than the value of C_{Boot} , as shown in [Equation 5](#).

$$C_{VDD} = 1 \text{ }\mu\text{F}$$
(5)

The bootstrap and bias capacitors must be ceramic types with X7R dielectric. The voltage rating must be twice that of the maximum V_{DD} considering capacitance tolerances once the devices have a DC bias voltage across them and to ensure long-term reliability.

8.2.2.2 Select External Bootstrap Diode and Its Series Resistor

The bootstrap capacitor is charged by the V_{DD} through the external bootstrap diode every cycle when low-side MOSFET turns on. The charging of the capacitor involves high peak currents, and therefore transient power dissipation in the bootstrap diode may be significant and the conduction loss also depends on its forward voltage drop. Both the diode conduction losses and reverse recovery losses contribute to the total losses in the gate driver circuit.

For the selection of external bootstrap diodes, see [AN-1317 Selection of External Bootstrap Diode for LM510X Devices](#) (SNVSA083). Bootstrap resistor R_{BOOT} is selected to reduce the inrush current in D_{BOOT} and limit the ramp up slew rate of voltage of V_{HB-HS} during each switching cycle, especially when HS pin have excessive negative transient voltage. R_{BOOT} recommended value is between $2 \text{ }\Omega$ and $10 \text{ }\Omega$ depending on diode selection. A current limiting resistor of $2.2 \text{ }\Omega$ is selected to limit inrush current of bootstrap diode, and the estimated peak current on the D_{Boot} is shown in [Equation 6](#).

$$I_{DBoot(pk)} = \frac{V_{DD} - V_{DH}}{R_{Boot}} = \frac{10 \text{ V} - 1 \text{ V}}{2.2 \text{ }\Omega} \approx 4 \text{ A}$$

where

- V_{DH} is the bootstrap diode forward voltage drop
- (6)

8.2.2.3 Selecting External Gate Driver Resistor

The external gate driver resistor, R_{GATE} , is sized to reduce ringing caused by parasitic inductances and capacitances and also to limit the current coming out of the gate driver.

Peak HO pullup current are calculated in [Equation 7](#).

$$I_{OHH} = \frac{V_{DD} - V_{DH}}{R_{HOH} + R_{Gate} + R_{GFET_Int}} = \frac{10 \text{ V} - 1 \text{ V}}{1.2 \text{ V} / 100 \text{ mA} + 4.7 \text{ }\Omega + 2.2 \text{ }\Omega} = 0.48 \text{ A}$$

where

- I_{OHH} = Peak pullup current
 - V_{DH} = Bootstrap diode forward voltage drop
 - R_{HOH} = Gate driver internal HO pullup resistance, provide by driver data sheet directly or estimated from the testing conditions, that is $R_{HOH} = V_{OHH} / I_{HO}$
 - R_{Gate} = External gate drive resistance
 - R_{GFET_Int} = MOSFET internal gate resistance, provided by transistor data sheet
- (7)

Similarly, Peak HO pulldown current is shown in [Equation 8](#).

$$I_{OLH} = \frac{V_{DD} - V_{DH}}{R_{HOL} + R_{Gate} + R_{GFET_Int}}$$

where

- R_{HOL} is the HO pulldown resistance (8)

Peak LO pullup current is shown in Equation 9.

$$I_{OHL} = \frac{V_{DD}}{R_{LOH} + R_{Gate} + R_{GFET_Int}}$$

where

- R_{LOH} is the LO pullup resistance (9)

Peak LO pulldown current is shown in Equation 10.

$$I_{OLL} = \frac{V_{DD}}{R_{LOL} + R_{Gate} + R_{FET_Int}}$$

where

- R_{LOL} is the LO pulldown resistance (10)

For some scenarios, if the applications require fast turnoff, an anti-paralleled diode on R_{Gate} could be used to bypass the external gate drive resistor and speed up turnoff transition.

8.2.2.4 Estimate the Driver Power Loss

The total driver IC power dissipation can be estimated through the following components.

1. Static power losses, P_{QC} , due to quiescent current – I_{DD} and I_{HB}

$$P_{QC} = V_{DD} \times I_{DD} + (V_{DD} - V_{DH}) \times I_{HB} \quad (11)$$

2. Level-shifter losses, P_{IHBS} , due high-side leakage current – I_{HBS}

$$P_{IHBS} = V_{HB} \times I_{HBS} \times D$$

where

- D is the high-side switch duty cycle (12)

3. Dynamic losses, $P_{QG1\&2}$, due to the FETs gate charge – Q_G

$$P_{QG1\&2} = 2 \times V_{DD} \times Q_G \times f_{SW} \times \frac{R_{GD_R}}{R_{GD_R} + R_{Gate} + R_{GFET_Int}}$$

where

- Q_G = Total FETs gate charge
- f_{SW} = Switching frequency
- R_{GD_R} = Average value of pullup and pulldown resistor
- R_{Gate} = External gate drive resistor
- R_{GFET_Int} = Internal FETs gate resistor (13)

4. Level-shifter dynamic losses, P_{LS} , during high-side switching due to required level-shifter charge on each switching cycle – Q_P

$$P_{LS} = V_{HB} \times Q_P \times f_{SW} \quad (14)$$

In this example, the estimated gate driver loss in LM5109A is shown in Equation 15.

$$P_{LM5109A} = 10\text{ V} \times 0.6\text{ mA} + 9\text{ V} \times 0.2\text{ mA} + 72\text{ V} \times 10\text{ }\mu\text{A} \times 0.95 + 2 \times 10 \times 17\text{ nC} \times 500\text{ kHz} \times \frac{12\text{ }\Omega}{12\text{ }\Omega + 4.7\text{ }\Omega + 2.2\text{ }\Omega} + 72\text{ V} \times 0.5\text{ nC} \times 500\text{ kHz} = 0.134\text{ W} \quad (15)$$

For a given ambient temperature, the maximum allowable power loss of the IC can be defined as shown in Equation 16.

$$P_{LM5109A} = \frac{T_J - T_A}{R_{\theta JA}}$$

where

- $P_{LM5109B}$ = The total power dissipation of the driver
 - T_J = Junction temperature
 - T_A = Ambient temperature
 - $R_{\theta JA}$ = Junction-to-ambient thermal resistance
- (16)

The thermal metrics for the driver package is summarized in the [Thermal Information](#) table of the data sheet. For detailed information regarding the thermal information table, please refer to the [Semiconductor and IC Package Thermal Metrics](#) (SPRA953).

8.2.3 Application Curves

[Figure 15](#) and [Figure 16](#) shows the rising and falling time as well as turnon and turnoff propagation delay testing waveform in room temperature, and waveform measurement data (see the bottom part of the waveform). Each channel (HI, LI, HO, and LO) is labeled and displayed on the left hand of the waveforms.

The testing condition: load capacitance is 1 nF, $V_{DD} = 12\text{ V}$, $f_{SW} = 500\text{ kHz}$.

HI and LI share one same input from function generator, therefore, besides the propagation delay and rising and falling time, the difference of the propagation delay between HO and LO gives the propagation delay matching data.

$C_L = 1\text{ nF}$ $V_{DD} = 12\text{ V}$ $f_{SW} = 500\text{ kHz}$

Figure 15. Rising Time and Turnon Propagation Delay

$C_L = 1\text{ nF}$ $V_{DD} = 12\text{ V}$ $f_{SW} = 500\text{ kHz}$

Figure 16. Falling Time and Turnoff Propagation Delay

9 Power Supply Recommendations

The recommended bias supply voltage range for LM5109A is from 8 V to 14 V. The lower end of this range is governed by the internal undervoltage lockout (UVLO) protection feature of the V_{DD} supply circuit blocks. The upper end of this range is driven by the 18-V absolute maximum voltage rating of the V_{DD} . TI recommends keeping a 4-V margin to allow for transient voltage spikes.

The UVLO protection feature also involves a hysteresis function. This means that once the device is operating in normal mode, if the V_{DD} voltage drops, the device continues to operate in normal mode as long as the voltage drop does not exceed the hysteresis specification, V_{DDH} . If the voltage drop is more than hysteresis specification, the device shuts down. Therefore, while operating at or near the 8-V range, the voltage ripple on the auxiliary power supply output must be smaller than the hysteresis specification of LM5109A to avoid triggering device-shutdown.

A local bypass capacitor must be placed between the VDD and GND pins. And this capacitor must be located as close to the device as possible. A low-ESR, ceramic surface mount capacitor is recommended. TI recommends using 2 capacitors across VDD and GND: a 100-nF, ceramic surface-mount capacitor for high-frequency filtering placed very close to VDD and GND pin, and another surface-mount capacitor, 220-nF to 10- μ F, for IC bias requirements. In a similar manner, the current pulses delivered by the HO pin are sourced from the HB pin. Therefore a 22-nF to 220-nF local decoupling capacitor is recommended between the HB and HS pins.

10 Layout

10.1 Layout Guidelines

Optimum performance of high and low-side gate drivers cannot be achieved without taking due considerations during circuit board layout. The following points are emphasized:

1. Low ESR / ESL capacitors must be connected close to the IC between VDD and VSS pins and between HB and HS pins to support high peak currents being drawn from VDD and HB during the turn-on of the external MOSFETs.
2. To prevent large voltage transients at the drain of the top MOSFET, a low ESR electrolytic capacitor and a good quality ceramic capacitor must be connected between the MOSFET drain and ground (VSS).
3. In order to avoid large negative transients on the switch node (HS) pin, the parasitic inductances between the top MOSFET source and the of the bottom MOSFET drain (synchronous rectifier) must be minimized.
4. Grounding considerations:
 - The first priority in designing grounding connections is to confine the high peak currents that charge and discharge the MOSFET gates to a minimal physical area. This will decrease the loop inductance and minimize noise issues on the gate terminals of the MOSFETs. The gate driver should be placed as close as possible to the MOSFETs.
 - The second consideration is the high current path that includes the bootstrap capacitor, the bootstrap diode, the local ground referenced bypass capacitor, and the low-side MOSFET body diode. The bootstrap capacitor is recharged on a cycle-by-cycle basis through the bootstrap diode from the ground referenced VDD bypass capacitor. The recharging occurs in a short time interval and involves high peak current. Minimizing this loop length and area on the circuit board is important to ensure reliable operation.

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) Part marking: There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
