

# LMK03318 1PLL、8出力、EEPROM内蔵、超低ノイズ・ジッタのクロック・ジェネレータ・ファミリ

## 1 特長

- 超低ノイズ、高性能
  - ジッタ: 標準値100fs RMS、 $F_{OUT} > 100\text{MHz}$
  - PSNR: -80dBc、堅牢な電源ノイズ耐性
- 柔軟なデバイス・オプション
  - 最大8つのAC-LVPECL、AC-LVDS、AC-CML、HCSL、LVCMOS出力を任意の組み合わせで使用可能
  - ピン・モード、 $I^2C$ モード、EEPROMモード
  - ピンで選択可能な71のプログラム済みのデフォルト・スタートアップ・オプション
- 自動または手動の選択によるデュアル入力
  - 水晶振動子入力: 10~52MHz
  - 外部入力: 1~300MHz
- 周波数マーキング・オプション
  - 低コストのプル可能な水晶振動子を基準に使用した、きめ細かい周波数マーキング
  - 出力分周器を使用した、グリッチレスな粗い周波数マーキング(%)
- その他の特長
  - 電源: 3.3Vコア、1.8V、2.5V、または3.3V出力
  - 工業用温度範囲: (-40°C ~ +85°C)

## 2 アプリケーション

- スイッチおよびルータ
- ネットワークおよびテレコム・ライン・カード
- サーバーおよびストレージ・システム
- 無線基地局
- PCIe Gen1、Gen2、Gen3、Gen4
- 試験/測定機器
- 放送用インフラストラクチャ

## 3 概要

LMK03318デバイスは超低ノイズの PLLATINUM™クロック・ジェネレータであり、1つのフラクショナルN周波数シンセサイザと内蔵VCO、柔軟なクロック分配およびファンアウトといった特長を備え、ピンで選択可能な構成状態がオンチップのEEPROMに格納されています。このデバイスは、各種の数ギガビット速度のシリアル・インターフェイスおよびデジタル・デバイス用に複数のクロックを生成できるため、BOMコストと基板面積を削減し、複数の発振器とクロック分配デバイスを置き換えることで信頼性を向上できます。超低ジッタにより、高速シリアル・リンクにおけるビット・エラー・レート(BER)を低減します。

### 製品情報<sup>(1)</sup>

| 型番       | パッケージ     | 本体サイズ(公称)     |
|----------|-----------|---------------|
| LMK03318 | WQFN (48) | 7.00mm×7.00mm |

(1) 提供されているすべてのパッケージについては、巻末の注文情報を参照してください。

## 4 改訂履歴

### Revision D (December 2017) から Revision E に変更 Page

|                                                                                                              |     |
|--------------------------------------------------------------------------------------------------------------|-----|
| • Clarified note about $V_{OH}$ (rail-to-rail swing only with $V_{DDO} = 1.8\text{ V} \pm 5\%$ ).....        | 12  |
| • Changed Slew Rate minimum and maximum from: 2.25 V/ns and 5 V/ns to: 1 V/ns and 4 V/ns, respectively ..... | 14  |
| • Updated PRODID reset value to be 0x33 (was 0x31).....                                                      | 71  |
| • Updated REVID reset value to be 0x02 (was 0x01) .....                                                      | 71  |
| • Added the <i>Support for PCB Temperature up to 105°C</i> subsection.....                                   | 133 |

### Revision C (August 2017) から Revision D に変更 Page

|                                                                                                                             |     |
|-----------------------------------------------------------------------------------------------------------------------------|-----|
| • 「アプリケーション」セクションの箇条書き項目を追加 .....                                                                                           | 1   |
| • Added <i>PCIe Clock Output Jitter</i> table.....                                                                          | 17  |
| • Added tablenotes to <a href="#">Table 10</a> .....                                                                        | 57  |
| • Changed the first paragraph of the <i>Powering Up From Single-Supply Rail</i> section .....                               | 129 |
| • Changed the first paragraph of the <i>Powering Up From Split-Supply Rails</i> section and <a href="#">Figure 84</a> ..... | 130 |
| • Changed the first paragraph and added new content to the <i>Slow Power-Up Supply Ramp</i> section .....                   | 130 |
| • Changed the first paragraph of the <i>Non-Monotonic Power-Up Supply Ramp</i> section .....                                | 131 |

### Revision B (August 2016) から Revision C に変更 Page

|                                                                                                 |    |
|-------------------------------------------------------------------------------------------------|----|
| • Added a table note to <i>Recommended Operating Conditions</i> explaining the NOM values ..... | 8  |
| • Changed $V_{bb} = 1.3\text{ V}$ to 1.8 in <a href="#">Figure 45</a> .....                     | 35 |

### Revision A (December 2015) から Revision B に変更 Page

|                                                                          |     |
|--------------------------------------------------------------------------|-----|
| • Changed title from Configuring the PLL to Device Functional Modes..... | 32  |
| • Changed title from Interface and Control to Programming .....          | 50  |
| • Added new sections to Power Supply Recommendations .....               | 129 |

## 5 概要（続き）

PLLについて、差動クロック、シングルエンド・クロック、または水晶振動子入力を基準クロックとして選択できます。選択した基準入力を使用して、VCO周波数を基準入力周波数の整数倍または分数倍にロックできます。VCO周波数は4.8GHzと5.4GHzの間で調整が可能です。PLLはアプリケーションの必要に応じて、事前定義またはユーザー定義のループ帯域幅を柔軟に選択できます。PLLには後処理分周器があり、2、3、4、5、6、7、または8分周を選択できます。

すべての出力チャンネルは、PLLからの分周されたVCOクロックを、出力分周器のソースとして選択し、最終的な出力周波数を設定できます。また、一部の出力チャンネルはPLL用の基準入力を別のソースとして独立に選択し、対応する出力バッファへバイパスできます。8ビットの出力分周器は、1～256の分周範囲(偶数または奇数)、最高1GHzの出力周波数、および出力位相同期機能をサポートしています。

すべての出力ペアはグラウンドを基準とするCMLドライバで、スイングをプログラムでき、LVDS、LVPECL、CMLレシーバとAC結合により接続できます。また、すべての出力ペアはそれぞれ独立に、HCSL出力または2×1.8V LVCMOS出力としても構成可能です。出力では、電圧を基準とするドライバ設計(従来型のLVDSおよびLVPECLドライバなど)に比べて、1.8Vで低消費電力、高性能および高い電源ノイズ耐性、および低いEMIを実現します。STATUSピンにより、2つの追加3.3V LVCMOS出力が得られます。これは、3.3V LVCMOS出力が必要で、デバイスのステータス信号が必要ない場合に使用できるオプション機能です。

このデバイスは、オンチップのプログラム可能なEEPROMまたは事前定義のROMメモリからの自己スタートアップ機能を備え、ピン制御で複数のカスタム・デバイス・モードを選択できるため、シリアルでのプログラムの必要がありません。デバイスのレジスタおよびオンチップEEPROM設定は、I<sup>2</sup>C互換のシリアル・インターフェイスにより完全にプログラム可能です。デバイスのスレーブ・アドレスはEEPROMでプログラムでき、LSBは3ステート・ピンにより設定できます。

このデバイスには2つの周波数マーキング・オプションが用意され、グリッチフリーの動作により、標準のコンプライアンスおよびシステム・タイミング・マージン・テストなど、システム設計検証テスト(DVT)をサポートします。また、内蔵の水晶発振器(XO)上の低コストなプル可能水晶振動子を使用し、この入力をPLLシンセサイザの基準として選択することで、きめ細かい周波数マーキング(ppm単位)をサポートできます。周波数のマーキング範囲は、水晶振動子のトリム感度と、オンチップのバラクタ範囲により決定されます。XO周波数マーキングは、ピンまたはI<sup>2</sup>Cにより制御でき、使いやすく高い柔軟性があります。粗い周波数マーキング(%)は、任意の出力チャンネルにおいて、I<sup>2</sup>Cインターフェイスで出力分周値を変更することにより利用でき、出力クロックを同期して停止および再開することで、分周器の変更時にグリッチやラント・パルスを防止します。

内部的な電力コンディショニングにより、電源ノイズ除去(PSNR)が非常に優れているため、電力配信ネットワークのコストと複雑性を低減できます。アナログおよびデジタル・コア・ブロックは3.3V ±5%電源で動作し、出力ブロックは1.8V、2.5V、3.3V ±5%電源で動作します。

## 6 デバイス比較表

表 1. 各種の積分帯域幅におけるLVPECL出力ジッタ

| 出力周波数(MHz) | 積分帯域幅                    | 標準ジッタ(ps, rms) |
|------------|--------------------------|----------------|
| < 100      | 12kHz～5MHz               | 0.15           |
| > 100      | 1kHz～5MHz<br>12kHz～20MHz | 0.1            |

## 7 Pin Configuration and Functions

### Pin Functions

| 30                                                | GPIO2   | LVCMOS    | Multifunction input (3-state or 2-state).                                                                                                                                           |
| 31                                                | GPIO3   | LVCMOS    | Multifunction input (3-state or 2-state).                                                                                                                                           |
| 32                                                | GPIO4   | LVCMOS    | Multifunction input (2-state).                                                                                                                                                      |
| 33                                                | GPIO5   | Universal | Multifunction input (2-state) or analog input for frequency margin.                                                                                                                 |

(1) Refer to [Device Configuration Control](#) for details on the digital control/interfaces.

## 8 Specifications

### 8.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)<sup>(1)</sup>

|                                                                                                              | MIN  | MAX                   | UNIT |
|--------------------------------------------------------------------------------------------------------------|------|-----------------------|------|
| Supply voltage for input, synthesizer, control, and output blocks, VDD_IN, VDD_PLL, VDD_LDO, VDD_DIG, VDDO_x | −0.3 | 3.6                   | V    |
| Input voltage, clock and logic inputs, V <sub>IN</sub>                                                       | −0.3 | V <sub>DD</sub> + 0.3 | V    |
| Output voltage for clock and logic outputs, V <sub>OUT</sub>                                                 | −0.3 | V <sub>DD</sub> + 0.3 | V    |
| Junction temperature, T <sub>J</sub>                                                                         |      | 150                   | °C   |
| Storage temperature, T <sub>stg</sub>                                                                        | −65  | 150                   | °C   |

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute maximum-rated conditions for extended periods may affect device reliability.

### 8.2 ESD Ratings

|                                            | VALUE                                                                          | UNIT  |
|--------------------------------------------|--------------------------------------------------------------------------------|-------|
| V <sub>(ESD)</sub> Electrostatic discharge | Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>              | ±2000 |
|                                            | Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup> | ±500  |

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process. Manufacturing with less than 500-V HBM is possible with the necessary precautions. Pins listed as ±2000 V may actually have higher performance.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process. Manufacturing with less than 250-V CDM is possible with the necessary precautions. Pins listed as ±500 V may actually have higher performance.

### 8.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

|                                                                                     | MIN   | NOM | MAX   | UNIT |
|-------------------------------------------------------------------------------------|-------|-----|-------|------|
| Supply voltage for input, analog, control blocks, VDD_IN, VDD_PLL, VDD_LDO, VDD_DIG | 3.135 | 3.3 | 3.465 | V    |
| Supply voltage for output drivers (Differential, LVCMOS), VDDO_X <sup>(1)</sup>     | 1.7   | 1.8 | 3.465 | V    |
|                                                                                     | 1.7   | 2.5 | 3.465 |      |
|                                                                                     | 1.7   | 3.3 | 3.465 |      |
| Ambient temperature, T <sub>A</sub>                                                 | –40   | 25  | 85    | °C   |
| Junction temperature, T <sub>J</sub>                                                |       |     | 125   | °C   |
| Maximum VDD power-up ramp, dVDD/dt                                                  | 0.1   |     | 100   | ms   |
| EEPROM number of writes, WR                                                         |       |     | 100   |      |

(1) The 3 different NOM values are the 3 typical test voltages throughout the data sheet.

### 8.4 Thermal Information

| THERMAL METRIC <sup>(1)</sup> |                                              | LMK03318 <sup>(2) (3) (4)</sup> |                   |                   | UNIT |
|-------------------------------|----------------------------------------------|---------------------------------|-------------------|-------------------|------|
|                               |                                              | RHA (WQFN)                      |                   |                   |      |
|                               |                                              | 48 PINS                         |                   |                   |      |
|                               |                                              | Airflow (LFM) 0                 | Airflow (LFM) 200 | Airflow (LFM) 400 |      |
| R <sub>θJA</sub>              | Junction-to-ambient thermal resistance       | 26.47                           | 16.4              | 14.62             | °C/W |
| R <sub>θJC(top)</sub>         | Junction-to-case (top) thermal resistance    | 16.57                           | n/a               | n/a               | °C/W |
| R <sub>θJB</sub>              | Junction-to-board thermal resistance         | 6.84                            | n/a               | n/a               | °C/W |
| ψ <sub>JT</sub>               | Junction-to-top characterization parameter   | 0.23                            | 0.31              | 0.47              | °C/W |
| ψ <sub>JB</sub>               | Junction-to-board characterization parameter | 4.02                            | 3.86              | 3.84              | °C/W |
| R <sub>θJC(bot)</sub>         | Junction-to-case (bottom) thermal resistance | 1.06                            | n/a               | n/a               | °C/W |

(1) For more information about traditional and new thermal metrics, see [Semiconductor and IC Package Thermal Metrics](#).

(2) The package thermal resistance is calculated on a 4-layer JEDEC board.

(3) Package DAP connected to PCB GND plane with 16 thermal vias (0.3 mm diameter).

(4) ψ<sub>JB</sub> (junction to board) is used when the main heat flow is from the junction to the GND pad. Refer to the [Layout](#) section for more information on ensuring good system reliability and quality.

### 8.5 Thermal Information

| THERMAL METRIC <sup>(1)</sup>                                | CONDITION                                                        | LMK03318   | UNIT |
|--------------------------------------------------------------|------------------------------------------------------------------|------------|------|
|                                                              |                                                                  | RHA (WQFN) |      |
|                                                              |                                                                  | 48 PINS    |      |
| R <sub>θJA</sub> Junction-to-ambient thermal resistance      | 10-layer 200 mm × 250 mm board, 36 thermal vias, Airflow = 0 LFM | 10         | °C/W |
| ψ <sub>JB</sub> Junction-to-board characterization parameter | 10-layer 200 mm × 250 mm board, 36 thermal vias, Airflow = 0 LFM | 2.8        | °C/W |

(1) For more information about traditional and new thermal metrics, see [Semiconductor and IC Package Thermal Metrics](#) application report.

## 8.6 Electrical Characteristics - Power Supply

VDD\_IN, VDD\_PLL, VDD\_LDO, VDD\_DIG = 3.3 V ± 5%, VDDO\_x = 1.8 V ± 5%, 2.5 V ± 5%, 3.3 V ± 5%, T<sub>A</sub> = –40°C to +85°C<sup>(1)(2)</sup>

| PARAMETER |                                       | TEST CONDITIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | MIN | TYP | MAX | UNIT |
|-----------|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|-----|-----|------|
| IDD       | Core current consumption, per block   | Primary input (differential or single-ended) - active                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |     | 10  |     | mA   |
|           |                                       | Secondary input (differential or single-ended) - active                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |     | 10  |     |      |

| C <sub>on-chip-12p-load</sub>  | On-chip tunable capacitor variation over VT across crystal load of 12 pF | Frequency accuracy of crystal over temperature, aging and initial accuracy < ±25 ppm. |     |     | 1.5 | pF     |
| f <sub>PR</sub>                | Pulling range                                                            | Crystal C <sub>0</sub> /C <sub>1</sub> < 250                                          |     | ±50 |     | ppm    |

- (1) Parameter is specified by characterization and is not tested in production.
- (2) The crystal pullability ratio is considered in the case where the XO frequency margining option is enabled. The actual pull range depends on the crystal pullability, as well as on-chip capacitance (C<sub>on-chip</sub>), device crystal oscillator input capacitance (C<sub>XO</sub>), PCB stray capacitance (C<sub>PCB</sub>), and any installed on-board tuning capacitance (C<sub>TUNE</sub>). Trim sensitivity or pullability (ppm/pF), TS = C<sub>1</sub> × 1e6 / [2 × (C<sub>0</sub> + C<sub>L</sub>)<sup>2</sup>]. If the total external capacitance is less than the crystal C<sub>L</sub>, the crystal oscillates at a higher frequency than the nominal crystal frequency. If the total external capacitance is higher than C<sub>L</sub>, the crystal oscillates at a lower frequency than nominal.
- (3) Using a crystal with higher ESR can degrade output phase noise and may impact crystal start-up.
- (4) Verified with crystals specified for a load capacitance of C<sub>L</sub> = 9 pF. PCB stray capacitance was measured to be 1 pF. Crystals tested: 19.2-MHz TXC (Part Number: 7M19272001), 19.44 MHz TXC (Part Number: 7M19472001), 25 MHz TXC (Part Number: 7M25072001), 38.88-MHz TXC (Part Number: 7M38872001), 49.152-MHz TXC (Part Number: 7M49172001), 50-MHz TXC (Part Number: 7M50072001).

## 8.8 Non-Pullable Crystal Characteristics (SECREP\_P, SECREP\_N)

| ODC <sup>(3)</sup>               | Output Duty Cycle                                       | 45%                                        |     | 55%  |        |
| R <sub>OUT</sub>                 | Output Impedance                                        |                                            | 50  |      | Ω      |

(1) Refer to [Parameter Measurement Information](#) for relevant test conditions.

(2) The 1.8-V LVC MOS driver supports rail-to-rail output swing only when powered from VDDO = 1.8 V ± 5% (recommended VDDO for use with LVC MOS output format). V<sub>OH</sub> level is NOT rail-to-rail for VDDO = 2.5 V or 3.3 V due to the dropout voltage of the output channel's internal LDO regulator.

(3) Ensured by characterization.

## 8.13 LVC MOS Output Characteristics (STATUS[1:0])

## 10 Detailed Description

### 10.1 Overview

The LMK03318 generates eight outputs with less than 0.2 ps, rms maximum random jitter in integer PLL mode and less than 0.35 ps, rms maximum random jitter in fractional PLL mode with a crystal input or a clean external reference input.

### 10.2 Functional Block Diagram

Copyright © 2016, Texas Instruments Incorporated

#### NOTE

Input and control blocks are compatible with 1.8 V, 2.5 V, or 3.3 V I/O voltage levels.

## 10.3 Feature Description

### 10.3.1 Device Block-Level Description

The LMK03318 includes an on-chip fractional PLL with integrated VCO that supports a frequency range of 4.8 GHz to 5.4 GHz. The PLL block consists of an input selection MUX, a phase frequency detector (PFD), charge pump, on-chip passive loop filter that only needs an external capacitor to ground, a feedback divider that can support both integer and fractional values, and a delta-sigma engine for spur suppression in fractional PLL mode. The universal inputs support single-ended and differential clocks in the frequencies of 1 MHz to 300 MHz; the secondary input additionally supports crystals in the frequencies of 10 MHz to 52 MHz. When the PLL operates with the crystal as its reference, the output frequencies can be margined based on changing the on-chip capacitor loading on each leg of the crystal. Completing the device is the combination of integer output dividers and universal output buffers. The PLL is powered by on-chip low dropout (LDO) linear voltage regulators, and the regulated supply network is partitioned such that the sensitive analog supplies are running from separate LDOs than the digital supplies which use their own LDO. The LDOs provide isolation of the PLL from any noise in the external power supply rail with a PSNR of better than  $-70$  dBc at 50-kHz to 1-MHz ripple frequencies at 1.8-V output supplies and better than  $-80$  dBc at 50-kHz to 1-MHz ripple frequencies at  $> 2.5$ -V output supplies. The regulator capacitor pins must each be connected to ground by 10- $\mu$ F capacitors to ensure stability.

### 10.3.2 Device Configuration Control

[Figure 41](#) shows the relationships between device states, the configuration pins, device initialization and configuration, and device operational modes. In hard-pin-configuration mode, the state of the configuration pins determines the configuration of the device as selected from all device states programmed in the on-chip ROM. In soft-pin-configuration mode, the state of the configuration pins determines the initialized state of the device as programmed in the on-chip EEPROM. In either mode, the host can update any device configuration after the device enables the host interface and the host writes a sequence that updates the device registers. Once the device configuration is set, the host can also write to the on-chip EEPROM for a new set of power-up defaults based on the configuration pin settings in the soft-pin-configuration mode. A system may transition a device from hard-pin mode to soft-pin mode by changing the state of the HW\_SW\_CTRL pin, then triggering a device power cycling via the PDN pin. In reset mode, the device disables the outputs so that unwanted sporadic activity associated with device initialization does not appear on the device outputs. [Table 2](#) lists the functionality of the GPIO[5:0] pins during hard pin and soft pin modes.

## Feature Description (continued)

**Figure 41. LMK03318 Simplified Programming Flow**

**Table 2. GPIO Pin Mapping for Hard Pin Mode and Soft Pin Mode**

| PIN NAME | HARD-PIN MODE                     |       | SOFT-PIN MODE                                                 |       |
|----------|-----------------------------------|-------|---------------------------------------------------------------|-------|
|          | FUNCTION                          | STATE | FUNCTION                                                      | STATE |

| GPIO3    |                                   | 2     |                                                               | 3     |
| GPIO4    |                                   | 2     | Frequency margining enable                                    | 2     |
| GPIO5    |                                   | 2     | Frequency margining offset select                             | 8     |

### 10.3.2.1 Hard-Pin Mode (HW\_SW\_CTRL = 1)

In this mode, the GPIO[5:0] pins allow hardware pin configuration of the PLL synthesizer, its input clock selection, and output frequency and type selection. I²C is still enabled, and the LSB of device address is set to 00. The GPIO pins are 2-state and are sampled or latched at POR — the combination selects one of 64 page settings that are predefined in on-chip ROM. In this mode, automatic output divider and PLL post divider synchronization is performed on power up or upon toggling PDN. [Table 14](#), [Table 15](#), [Table 17](#), and [Table 18](#) show the predefined ROM configurations according to the GPIO[5:0] pin settings.

Following are the blocks that are configured by the GPIO[5:0] pins.

#### 10.3.2.1.1 PLL Block

Sets the PLL synthesizer frequency and loop bandwidth by configuring registers related to the PLL dividers, input frequency doubler, and PLL power down.

#### 10.3.2.1.2 Output Buffer Auto Mute

When the selected source of an output MUX is invalid (for example, the PLL is unlocked or selected reference input is not present), the individual output mute controls will determine output mute state per the ROM default settings (CH\_x\_MUTE=0x1, CHx\_MUTE\_LVL=0x3):

1. In differential mode, the positive output node is driven to the internal regulator output voltage rail (when AC coupled to load), and the negative output node is driven to the GND rail.
2. In LVCMOS mode, a DC connection to the receiver is assumed, so the output in a “mute” condition will be forced LOW.

#### 10.3.2.1.3 Input Block

The input block sets the input type for primary and secondary inputs, selects input MUX type for the PLL, and selects R divider value for primary input to the input MUX.

#### 10.3.2.1.4 Channel Mux

The channel mux controls the channel mux selection for each channel.

#### 10.3.2.1.5 Output Divider

The output divider sets the 8-bit output divide value for each channel (/1 to /256).

#### 10.3.2.1.6 Output Driver Format

The output driver format selects the output format for each driver pair, or disable channel.

#### 10.3.2.1.7 Status MUX, Divider and Slew Rate

These blocks select the status pins as either 3.3-V LVCMOS PLL clock outputs or status outputs. When configured as LVCMOS clock outputs, these blocks select divider values and rise/fall time settings.

### 10.3.2.2 Soft-Pin Programming Mode (HW\_SW\_CTRL = 0)

In this mode, I<sup>2</sup>C is enabled and GPIO[3:2] are purposed as 3-state pins (tied to VDD\_DIG, GND or V<sub>IM</sub>) and are used to select one of 6 EEPROM pages and one register default setting (2 of 9 states are invalid). GPIO[0] is also purposed as a 2-state output synchronization (active-low SYNCN) function, GPIO[1] is now purposed as a 3-state I<sup>2</sup>C address function to change last 2 bits of I<sup>2</sup>C address (ADD; 0x0 is GND, 0x1 is V<sub>IM</sub>, and 0x3 is VDD\_DIG). GPIO[5] is purposed as a multi-state input for the MARGIN function and GPIO[4] is purposed as an input that enables or disables hardware margining. The GPIO pins are sampled and latched at POR.

#### NOTE

No software reset or power cycling must occur during EEPROM programming or else it will be corrupted. Please refer to [Programming](#) for more details on the EEPROM programming.

GPIO[3:2] allows hardware pin configuration for the PLL synthesizers, their respective input clock selection modes, the crystal input frequency margining option, all output channel blocks, comprised of channel muxes, dividers, and output drivers. The GPIO inputs[3:2] are sampled and latched at power-on reset (POR), and select one of 6 EEPROM pages, which are custom-programmable. When GPIO[3:2] are left floating, EEPROM is not used, and the hardware register default settings are loaded. [Table 10](#), [Table 11](#), [Table 12](#) and [Table 13](#) show the predefined EEPROM configurations according to the GPIO[3:2] pin settings.

The following sections give a brief overview of the register settings for each block configured by the GPIO[3:2] pin modes.

#### 10.3.2.2.1 Device Config Space

An 8-b for unique identifier programmed to EEPROM that can be used to distinguish between each EEPROM page.

#### 10.3.2.2.2 PLL Block

The PLL block sets the PLL synthesizer frequency and loop bandwidth by configuring registers related to the PLL dividers, input frequency doubler, and PLL power down.

#### 10.3.2.2.3 Output Buffer Auto Mute

When the selected source of an output MUX is invalid (for example, the PLL is unlocked or selected reference input is not present), the individual output mute controls determine output mute state per the EEPROM default settings (CH\_x\_MUTE=0x1, CHx\_MUTE\_LVL=0x3):

1. In differential mode, the positive output node is driven to the internal regulator output voltage rail (when AC coupled to load), and the negative output node is driven to the GND rail.
2. In LVCMOS mode, assuming there is a DC connection to the receiver, the output in a *mute* condition is forced LOW.

#### 10.3.2.2.4 Input Block

The input block sets the input type for primary and secondary inputs, selects input MUX type for the PLL and selects R divider value for primary input to the input MUX.

#### 10.3.2.2.5 Channel Mux

The channel mux controls the channel mux selection for each channel.

#### 10.3.2.2.6 Output Divider

The output divider sets the 8-bit output divide value for each channel (/1 to /256).

#### 10.3.2.2.7 Output Driver Format

The output driver format selects the output format for each driver pair, or disables channel.

#### 10.3.2.2.8 Status MUX, Divider and Slew Rate

These blocks select the status pins as either 3.3-V LVCMOS PLL clock outputs or status outputs. When configured as LVCMOS clock outputs, these blocks select divider values and rise/fall time settings.

### 10.3.2.3 Register File Reference Convention

Figure 42 shows the method that this document employs to refer to an individual register bit or a grouping of register bits. If a drawing or text references an individual bit the format is to specify the register number first and the bit number second. The LMK03318 contains 124 registers that are 8 bits wide. The register addresses and the bit positions both begin with the number zero (0). A period separates the register address and bit address. The first bit in the register file is address 'R0.0' meaning that it is located in Register 0 and is bit position 0. The last bit in the register file is address R31.7 referring to the 8th bit of register address 31 (the 32nd register in the device). Figure 42 lists specific bit positions as a number contained within a box. A box with the register address encloses the group of boxes that represent the bits relevant to the specific device circuitry in context.

**Figure 42. LMK03318 Register Reference Format**

## 10.4 Device Functional Modes

The PLL in LMK03318 can be configured to accommodate various input and output frequencies either through I<sup>2</sup>C programming interface or in the absence of programming, the PLL can be configured by the ROM page, EEPROM page, or register default settings selected through the control pins. The PLL can be configured by setting its Smart Input MUX, Reference Divider, PLL Loop Filter, Feedback Divider, Prescaler Divider and Output Dividers.

For the PLL to operate in closed-loop mode, the following condition in Equation 1 has to be met when using primary input or secondary input for the reference clock ( $F_{REF}$ ).

$$F_{VCO} = (F_{REF}/R) \times D \times [(INT + NUM/DEN)/M]$$

where

- $F_{VCO}$ : PLL/VCO Frequency
  - $F_{REF}$ : Frequency of selected reference input clock
  - D: PLL input frequency doubler, 1=Disabled, 2=Enabled
  - INT: PLL feedback divider integer value (12 bits, 1 to 4095)
  - NUM: PLL feedback divider fractional numerator value (22 bits, 0 to 4194303)
  - DEN: PLL feedback divider fractional denominator value (22 bits, 1 to 4194303)
  - R: Primary reference divider value (3 bits, 1 to 8); R = 1 for secondary reference
  - M: PLL reference input divider value (5 bits, 1 to 32)
- (1)

The output frequency is related to the PLL/VCO frequency or the reference input frequency (based on the output MUX selection) as given in Equation 2 and Equation 3:

$$F_{OUT} = F_{REF} \text{ when reference input clock selected by OUTMUX} \quad (2)$$

$$F_{OUT} = F_{VCO} / (P \times OUTDIV) \text{ when PLL is selected by OUTMUX}$$

where

- OUTDIV: Output divider value (8 bits, 1 to 256)
  - P: PLL post-divider value (2, 3, 4, 5, 6, 7, 8)
- (3)

### 10.4.1 Smart Input MUX

The PLL has a Smart Input MUX. The input selection mode of the PLL can be configured using the 3-state REFSEL pin or programmed through I<sup>2</sup>C. The Smart Input MUX supports auto-switching and manual-switching using control pin (or through register). The Smart Input MUX is designed such that glitches created during switching in both auto and manual modes are suppressed at the MUX output.

In the automatic mode, the frequencies of both primary (PRIREF) and secondary (SECREF) input clocks have to be within 2000 ppm. The phase of the input clocks can be any. To minimize phase jump at the output, TI recommends setting very low PLL loop bandwidth, set R29.7 = 1 and R51.7 = 1; the outputs that are not muted should have its respective mute bypass bit in R20 and R21 be set to 0 to ensure that these outputs are available during an input switchover event. In the case that the primary reference is detected to be unavailable, the input MUX automatically switches from the primary reference to the secondary reference. When primary reference is detected to be available again, the input MUX switches back to the primary reference. When both primary and secondary references are detected as unavailable, the input MUX waits on secondary reference until either the primary or the secondary reference is detected as available again. When both the primary and secondary reference inputs are detected as unavailable, LOS is active, and the PLL outputs are automatically disabled. The timing diagram of an auto-switch at the input MUX is shown in Figure 43.

**Figure 43. Smart Input MUX Auto-Switch Mode Timing Diagram**

## Device Functional Modes (continued)

R50[1-0] are the register bits that control the smart input MUX for the PLL and can be programmed through I<sup>2</sup>C. [Table 3](#) shows the input clock selection options for the PLL that are supported by the REFSEL pin or through I<sup>2</sup>C programming.

**Table 3. Input Clock Selection Through I<sup>2</sup>C Programming or REFSEL Pin**

| R50.1 | R50.0 | REFSEL          | MODE      | PLL REFERENCE         |
|-------|-------|-----------------|-----------|-----------------------|
| 0     | 0     | X               | Automatic | PLL prefers primary   |
| 0     | 1     | 0               | Manual    | PLL selects primary   |
| 0     | 1     | V <sub>IM</sub> | Manual    | PLL selects secondary |
| 0     | 1     | 1               | Automatic | PLL prefers primary   |
| 1     | 0     | X               | Manual    | PLL selects primary   |
| 1     | 1     | X               | Manual    | PLL selects secondary |

For those applications requiring device start-up from a crystal on the secondary input, do a one-time-only switchover to the primary input once available and, when auto-switch on the PLL's smart MUX is enabled, R51.2 can be set to 0 which automatically disables the secondary crystal input path after switchover to the primary input is complete. This removes coupling between the primary and secondary inputs and prevents input crosstalk components from appearing at the outputs. However, if the auto-switch between primary and secondary is desired at any point of normal device operation, R51.2 must be set to 1, PLL must be set to a very low loop bandwidth, and R20, R21, and R22 must be set to 0x0 to ensure minimal phase hit once PLL is relocked after switchover to either primary or secondary inputs. [Figure 44](#) shows flowchart of events triggered when R51.2 is set to 1 or 0 .

**Figure 44. Flowchart Describing Events When R51.2 is Set to 0 or 1**

### 10.4.2 Universal Input Buffer (PRI\_REF, SEC\_REF)

The primary reference can support differential or single-ended clocks. The secondary reference can support differential or single-ended clocks or crystal. The differential input buffers on both primary and secondary support internal  $50\ \Omega$  to ground or  $100\ \Omega$  termination between P and N followed by on-chip AC-coupling capacitors to internal self-biased circuitry. Internal biasing is offered before the on-chip AC-coupling capacitors when the clock inputs are AC coupled externally, and this is enabled by setting  $R29.0 = 1$  (for primary reference) or  $R29.1 = 1$  (for secondary reference). When the clock inputs are DC coupled, the internal biasing before the on-chip AC-coupling capacitors is disabled by settings  $R29.0 = 0$  (for primary reference) or  $R29.1 = 0$  (for secondary reference). Figure 45 shows the differential input buffer termination options implemented on both primary and secondary and the switches (SWLVDS, SWHCSL, SWAC) are controlled by  $R29[5-0]$ . Table 4 shows the primary and secondary buffer configuration matrix for LVPECL, CML, LVDS, HCSL and LVCMOS inputs.

### 10.4.3 Crystal Input Interface (SEC\_REF)

The LMK03318 implements an input crystal oscillator circuitry, known as the Pierce oscillator, shown in Figure 56. It is enabled when R50.7, R50.6, and R29.1 are set to 1, 0, and 1 respectively. The crystal oscillator circuitry includes programmable on-chip capacitances on each leg of the crystal and a damping resistor intended to minimize over-driven condition of the crystal. The recommended oscillation mode of operation for the input crystal is fundamental mode, and the recommended type of circuit for the crystal is parallel resonance with low or high pull-ability.

A crystal's load capacitance refers to all capacitances in the oscillator feedback loop. It is equal to the amount of capacitance seen between the terminals of the crystal in the circuit. For parallel resonant mode circuits, the correct load capacitance is necessary to ensure the oscillation of the crystal within the expected parameters. The LMK03318 has been characterized with 9 pF parallel resonant crystals with maximum motional resistance of 30  $\Omega$  and maximum drive level of 300  $\mu$ W.

The normalized frequency error of the crystal, due to load capacitance mismatch, can be calculated as Equation 4:

$$\frac{\Delta f}{f} = \frac{C_S}{2(C_{L,R} + C_0)} - \frac{C_S}{2(C_{L,A} + C_0)}$$

where

- $C_S$  is the motional capacitance of the crystal
- $C_0$  is the shunt capacitance of the crystal
- $C_{L,R}$  is the rated load capacitance for the crystal
- $C_{L,A}$  is the actual load capacitance in the implemented PCB for the crystal
- $\Delta f$  is the frequency error of the crystal
- $f$  is the rated frequency of the crystal.

(4)

The first 3 parameters can be obtained from the crystal vendor.

**Figure 56. Crystal Input Interface on Secondary Reference**

If reducing frequency error of the crystal is of utmost importance, a crystal with low pullability should be used. If frequency margining or frequency spiking is desired, a crystal with high pullability should be used to ensure that the desired frequency offset is added to the nominal oscillation frequency. A total of  $\pm 50$  ppm pulling range is obtained with a crystal whose ratio of shunt capacitance to motional capacitance ( $C_0/C_1$ ) is no more than 250.

The programmable capacitors on LMK03318 can be tuned from 14 pF to 24 pF in steps of 14 fF using either an analog voltage on GPIO5 in soft pin mode or through I<sup>2</sup>C in soft pin or hard pin mode. When using crystals with low pullability, the preferred method is to program R86.3 = 1, R86.2 = 0, and program the appropriate binary code to R104 and R105, in this exact order, that sets the required on-chip load capacitance for least frequency error. GPIO4 pin must be tied to VDD, and GPIO5 pin should be floating when device is operating in soft-pin mode. [Table 4](#) shows the binary code for on-chip load capacitance on each leg of crystal.

When using crystals with high pullability, the same method as above can be repeated for setting a fixed frequency offset to the nominal oscillation frequency according to [Equation 4](#). In case of a closed loop system where the crystal frequency can be dynamically changed based on a control signal, the LMK03318 must operate in soft-pin mode, the R86.3 must be programmed to 0, and the R86.2 must be programmed to 1. The GPIO5 pin is now configured as an 8-level input with a full-scale range of 0 V to 1.8 V, and every 200 mV corresponds to a frequency change according to [Equation 4](#). There are three possibilities to enable margining feature with GPIO5:

- Programming R86.3 = 0 and R86.2 = 1. In this case, status of GPIO4 pin is ignored.
- When R86.3 = 0 and R86.2 = 0 is programmed, GPIO4 must be tied to GND. Tying GPIO4 to VDD disables GPIO5 for margining purposes and R94 and R95 determine the on-chip load capacitance for the crystal. If any frequency offset is desired at the output, the appropriate binary code should be programmed to R94 and R95.
- When R86.3 = 1 and R86.2 = 0 is programmed, GPIO4 must be tied to GND. Tying GPIO4 to VDD disables GPIO5 for margining purposes and R104 and R105 determine the on-chip load capacitance for the crystal. If any frequency offset is desired at the output, the appropriate binary code should be programmed to R104 and R105.

There are two possibilities to drive the GPIO5 pin:

- The first method is to achieve the desired voltage between 0 V to 1.8 V according to [Analog Input Characteristics \(GPIO\[5\]\)](#). The pulldown resistor value sets the voltage on GPIO[5] pin that falls within one of eight settings whose pre-programmed on-chip crystal load capacitances are set by R88, R89, R90, R91, R92, R93, R94, R95, R96, R97, R98, R99, R100, R101, R102, and R103.
- The second method is using a low-pass filtered PWM signal to drive the 8-level GPIO5 pin as shown in [Figure 57](#). The PWM signal could be generated from the frequency difference between a highly stable TCXO and the output of LMK03318 that is provided as a feedback into the GPIO5 pin and used to adjust the on-chip load capacitance on the crystal input to reduce frequency errors from the crystal. This is a quick alternative that produces a frequency error at the LMK03318's output and could be acceptable to any application when compared to a full-characterization with a chosen crystal to understand the exact load pulling required to minimize frequency error at the LMK03318's output. More details on frequency margining are provided in [Application and Implementation](#).

**Figure 57. Crystal Load Capacitance Compensation Using PWM Signal**

The incremental load capacitance for each step should be programmed to R88, R89, R90, R91, R92, R93, R94, R95, R96, R97, R98, R99, R100, R101, R102, and R103 according to the chosen crystal's trim sensitivity specifications. The least-significant bit programmed to any of the XO offset register corresponds to a load capacitance delta of about 0.02 pF on the crystal input pins.

Good layout practices are fundamental to the correct operation and reliability of the oscillator. It is critical to locate the crystal components very close to the SECREF\_P and SECREF\_N pins to minimize routing distances. Long traces in the oscillator circuit are a very common source of problems. Don't route other signals across the oscillator circuit, and make sure power and high-frequency traces are routed as far away as possible to avoid crosstalk and noise coupling. If drive level of the crystal should be reduced, a damping resistor (less than 500 Ω) should be accommodated in the layout between the crystal leg and SECREF\_P pin. Vias in the oscillator circuit are recommended primarily for connections to the ground plane. Don't share ground connections; instead, make a separate connection to ground for each component that requires grounding. If possible, place multiple vias in parallel for each connection to the ground plane. The layout must be designed to minimize stray capacitance across the crystal to less than 2 pF total under all circumstances to ensure proper crystal oscillation.

#### 10.4.4 Reference Doubler

The primary and secondary references each have a frequency doubler that can be enabled by programming R57.4 = 1 for the primary reference and R72.4 = 1 for the secondary reference. Enabling the doubler allows a higher comparison frequency for the PLL and results in a 3-dB reduction in the in-band phase noise of the LMK03318 device's outputs. However, enabling the doubler poses the requirement of less than 0.5% duty cycle distortion of its reference input to minimize high spurious signals in the LMK03318's outputs. If the reference input duty cycle is requirement is not met, the higher order loop filter components (R3 and C3) of the PLL can be used to suppress the reference input spurs.

#### 10.4.5 Reference Divider (R)

The reference (R) divider is a continuous 3-b counter that is present on the primary reference before the smart input MUX of the PLL. The output of the R divider sets the input frequency for the smart input MUX and the auto switch capability of the smart input MUX can then be employed as long as the secondary input frequency is no more than 2000 ppm different from the output of the R divider, which is programmed in R52 for the PLL.

#### 10.4.6 Input Divider (M)

The input (M) divider is a continuous 5-b counter that is present after the smart input MUX of the PLL. The output of the M divider sets the PFD frequency to the PLL and should be in the range of 1 MHz to 150 MHz. The M divider is programmed in R53 for the PLL.

#### 10.4.7 Feedback Divider (N)

The N divider of the PLL includes fractional compensation and can achieve any fractional denominator (DEN) from 1 to 4,194,303. The integer portion, INT, is the whole part of the N divider value and the fractional portion, NUM / DEN, is the remaining fraction. N, NUM, and DEN are programmed in R58, R59, R60, R61, R62, R63, R64, and R65 for the PLL. The total programmed N divider value, N, is determined by:  $N = INT + NUM / DEN$ . The output of the N divider sets the PFD frequency to the PLL and should be in the range of 1 MHz to 150 MHz.

#### 10.4.8 Phase Frequency Detector (PFD)

The PFD of the PLL takes inputs from the input divider output and the feedback divider output and produces an output that is dependent on the phase and frequency difference between the two inputs. The allowable range of frequencies at the inputs of the PFD is from 1 MHz to 150 MHz.

#### 10.4.9 Charge Pump

The PLL has charge pump slices of 0.4 mA, 0.8 mA, 1.6 mA, or 6.4 mA. These slices can be selected in the following combinations to vary the charge pump current from 0.4 mA to 6.4 mA by programming R57[3-0] for the PLL.

#### 10.4.10 Loop Filter

The PLL supports programmable loop bandwidth from 200 Hz to 1 MHz. The loop filter components, R2, C1, R3, and C3, can be configured by programming R67, R68, R69, and R70 for the PLL. C2 for the PLL is an external component that is added on the LF pin. When the PLL is configured in the fractional mode, R69.0 should be set to 1 and R118[2-0] should be set to 0x7. When the PLL is configured in integer mode, R69.0 should be set to 0 and R118[2-0] should be set to 0x3 for second-order (NOTE: R69 should be set to 0x0) or 0x7 for third-order, respectively. When the PLL's loop bandwidth is desired to be set to 200 Hz, R120.0 should be set to 0. [Figure 58](#) shows the loop filter structure of the PLL.

It is important to set the PLL to best possible bandwidth to minimize output jitter. A high bandwidth ( $\geq 100$  kHz) provides best input signal tracking and is therefore desired with a clean input reference (clock generator mode). A low bandwidth ( $\leq 1$  kHz) is desired if the input signal quality is unknown (jitter cleaner mode). TI provides the WEBENCH Clock Architect that makes it easy to select the right loop filter components.

**Figure 58. Loop Filter Structure of PLL**

#### 10.4.11 VCO Calibration

The PLL of the LMK03318 includes an LC VCO that is designed using high-Q monolithic inductor to oscillate between 4.8 GHz and 5.4 GHz and has low phase-noise characteristics. The VCO must be calibrated to ensure that the clock outputs deliver optimal phase noise performance. Fundamentally, a VCO calibration establishes an optimal operating point within the tuning range of the VCO. While transparent to the user, the LMK03318 and the host system perform the following steps comprising a VCO calibration sequence:

1. **Normal Operation** - When the LMK03318 is in normal (operational) mode, the state of the power-down pin (PDN) is high.
2. **Entering the reset state** - If the user wishes to initialize the selected pin mode default settings (from ROM, EEPROM, or register default) and initiate a VCO calibration sequence, then the host system must place the device in reset through the PDN pin, or through software reset (R12.7) through I<sup>2</sup>C, or by removing and restoring device power. Pulling the PDN pin low or setting R12.7 = 0 places the device in the reset state.
3. **Exiting the reset state** - The device calibrates the VCO either by exiting the device reset state or through the device reset command initiated through the host interface. Exiting the reset state occurs automatically after power is applied and/or the system restores the state of the PDN or R12.7 from the low to high state. Exiting the reset state using the PDN pin causes the selected pin mode defaults to be loaded/reloaded into the device register bank. Invoking software reset through R12.7 does not reinitialize the registers; rather, the device retains settings related to the current clock frequency plan. Using this method allows for a VCO calibration for a frequency plan other than the default state (that is, the device calibrates the VCO based on the settings current register settings). The nominal state of this bit is high. Writing this bit to a low state and then returning it to the high state invokes a device reset without restoring the pin mode.
4. **Device stabilization** - After exiting the reset state as described in Step 3, the device monitors internal voltages and starts a reset timer. Only after internal voltages are at the correct level and the reset time has expired will the device initiate a VCO calibration. This ensures that the device power supplies and reference inputs have stabilized prior to calibrating the VCO.
5. **VCO Calibration** - The LMK03318 calibrates the VCO. During the calibration routine, the device mutes output channels configured with their respective auto-mute control enabled, so that they generate no spurious clock signals. After a successful calibration routine, the PLL will lock the VCO to the selected reference input.

### 10.4.12 Fractional Circuitry

The delta-sigma modulator is a key component of the fractional circuitry and is involved in noise shaping for better phase noise and spurs in the band of interest. The order of the delta sigma modulator is selectable from integer mode to third order and can be programmed in R66[1-0] for the PLL. There are also several dithering modes that are also programmed in R66[3-2] for the PLL.

#### 10.4.12.1 Programmable Dithering Levels

If used appropriately, dithering may be used to reduce sub-fractional spurs, but if used inappropriately, it can actually create spurs and increase phase noise. [Table 5](#) provides guidelines for the use of dithering based on the fractional denominator, after the fraction is reduced to lowest terms.

**Table 5. Dithering Recommendations**

| FRACTION                                                | RECOMMENDATION     | COMMENTS                                                                                                                                                   |
|---------------------------------------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fractional Numerator = 0                                | Disable Dithering  | This is often the worst case for spurs, and can actually be turned into the best case by disabling dithering. Performance is then similar to integer mode. |
| Equivalent Denominator < 20                             | Disable Dithering  | These fractions are not well randomized and dithering will likely create phase noise and spurs.                                                            |
| Equivalent denominator is not divisible by 2 or 3       | Disable Dithering  | There will be no sub-fractional spurs, so dithering is likely not to be very effective.                                                                    |
| Equivalent denominator > 200 and is divisible by 2 or 3 | Consider Dithering | Dithering may help reduce the sub-fractional spurs, but understand it may degrade the PLL phase noise.                                                     |

#### 10.4.12.2 Programmable Delta Sigma Modulator Order

The programmable fractional modulator order gives the opportunity to better optimize phase noise and spurs. Theoretically, higher order modulators push out phase noise to farther offsets, as described in [Table 6](#).

**Table 6. Delta Sigma Modulator Order Recommendations**

| ORDER                            | APPLICATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Integer Mode (Order = 0)         | If the fractional numerator is zero, it is best to run the PLL in integer mode to minimize phase noise and spurs.                                                                                                                                                                                                                                                                                                                                                        |
| First Order Modulator            | When the equivalent fractional denominator is 6 or less, the first order modulator theoretically has lower phase noise and spurs, so it always makes sense in these situations. When the fractional denominator is between 6 and about 20, consider using the first order modulator because the spurs might be far enough outside the loop bandwidth that they will be filtered. The first order modulator also does not create any sub-fractional spurs or phase noise. |
| Second and Third Order Modulator | The choice between 2nd and 3rd order modulator tends to be a little more application specific. If the fractional denominator is not divisible by 3, then the second and third order modulators will have spurs in the same offsets, so the third is generally better for spurs. However, if stronger levels of dithering is used, the third order modulator will create more close-in phase noise than the second order modulator.                                       |

Figure 59 and Figure 60 give an idea of the theoretical impact of the delta sigma modulator order on the shaping of the phase noise and spurs. In terms of phase noise, this is what one would theoretically expect if strong dithering was used for a well-randomized fraction. Dithering can be set to different levels or even disabled and the noise can be eliminated. In terms of spurs, they can change based on fraction, but they will theoretically be pushed out to higher phase detector frequencies. However, one must be aware that these are just THEORETICAL graphs and for offsets that are less than 5% of the phase detector frequency, other factors can impact the noise and spurs. In Figure 59, the curves all cross at 1/6th of the phase detector frequency and that this transfer function peaks at half of the phase detector frequency, which is assumed to be well outside the loop bandwidth. Figure 60 shows the impact of the phase detector frequency on the modulator noise.

Figure 59. Theoretical Delta Sigma Noise Shaping for a 100 MHz Phase Detector Frequency

Figure 60. Theoretical Delta Sigma Noise Shaping for 3rd Order Modulator

#### 10.4.13 Post Divider

Each PLL has a post divider that supports divide-by 2, 3, 4, 5, 6, 7, and 8 from the VCO frequency and distributed to the output section by programming R56[4-2] for PLL and R71[4-2] for PLL2.

#### 10.4.14 High-Speed Output MUX

The output section is made up of four high-speed output MUX's. Each of the four MUX able to select between primary reference, secondary reference or the divided PLLclock by programming R37[7-6], R39[7-6], R41[7-6], and R43[7-6]. Each of the four MUX's distributes individually to outputs 4, 5, 6, and 7. When reference doubler is enabled and any output MUX selects that reference input, the output frequency will be the same as the reference frequency (non-doubled) but the output phase could be the same or complementary of the reference input.

#### 10.4.15 High-Speed Output Divider

There are six high-speed output dividers and each supports divide values of 1 to 256. Outputs 0 and 1 share an output divider, as well as outputs 2 and 3. Outputs 4, 5, 6, and 7 have their own individual output dividers. The divide values are programmed in R33, R36, R38, R40, R42, and R44. These output dividers also support coarse frequency margining for all output divide values greater than 8 and can be enabled on any output channel by setting the appropriate bit in R24 to a 1. In such a use case, a dynamic change in the output divider value through I<sup>2</sup>C ensures that there are no glitches at the output irrespective of when the change is initiated. Depending on the VCO frequency and output divide values, as low as a 5% change can be initiated in the output frequency. An example case of coarse frequency margining on an output is shown in [Figure 61](#).

**Figure 61. Simplified Diagram for Coarse Frequency Margining**

#### 10.4.16 High-Speed Clock Outputs

Each output can be configured as AC-LVPECL, AC-LVDS, AC-CML, HCSL or LVCMOS by programming R31, R32, R34, R35, R37, R39, R41, and R43. Each output has the option to be muted or not, in case the source from which it is derived becomes invalid, by programming R22. An invalid source could be a primary or secondary reference that is no longer present or any PLL that is unlocked. When outputs are to be muted, R20 and R21 must each be programmed to 0xFF. Outputs 0 and 1 share an output supply (VDDO\_01), as well as outputs 2 and 3 (VDDO\_23). Outputs 4, 5, 6, 7 have individual output supplies (VDDO\_4, VDDO\_5, VDDO\_6, VDDO\_7). Each output supply can be independently set to 1.8 V, 2.5 V or 3.3 V. When a particular output is desired to be disabled, the bits [5:0] in the corresponding output control register (R31, R32, R34, R35, R37, R39, R41 or R43) must be set to 0x00. If any of outputs 4, 5, 6, and 7 and their output dividers are disabled; their corresponding supplies can be connected to GND.

The AC-LVDS, AC-CML, and AC-LVPECL output structure is given in Figure 62 where the tail currents can be programmed to either 4 mA, 6 mA, or 8 mA to generate output voltage swings that are compatible with LVDS, CML or LVPECL, respectively. Because this output structure is GND referenced, the output supplies can be operated from 1.8 V, 2.5 V or 3.3 V and offer lower power dissipation compared to traditional LVDS, CML, or LVPECL structures without any impact on jitter performance or other AC or DC specifications. Interfacing to LVDS, CML or LVPECL receivers are done with just an external AC-coupling capacitor for each output. No source termination is needed since the on-chip termination is automatically enabled when selecting AC-LVDS, AC-CML, or AC-LVPECL for good impedance matching to 50  $\Omega$  interconnects.

**Figure 62. Structure of AC-LVDS, AC-CML, and AC-LVPECL Output Stage**

The HCSL output structure is open drain and can be direct coupled or AC coupled to HCSL receivers with appropriate termination scheme. This output structure supports either on-chip 50  $\Omega$  termination or off-chip 50  $\Omega$  termination. The on-chip 50  $\Omega$  termination is provided primarily for convenience when driving short traces. In the case of driving long traces possibly through a connector, the on-chip termination should be disabled and a 50  $\Omega$  to GND termination at the receiver should be implemented. The output supplies can be operated from 1.8 V, 2.5 V or 3.3 V without any impact on jitter performance or other AC or DC specifications.

The LVCMOS outputs on each side (P and N) can be configured individually to be complementary or in-phase or can be turned off (high output impedance). The LVCMOS outputs are always at 1.8 V logic level irrespective of the output supply. In case 3.3-V LVCMOS outputs are needed, STATUS1 and/or STATUS0 can be configured as 3.3-V LVCMOS outputs.

Figure 63 through Figure 68 show recommendations for interfacing between LMK03318's high-speed clock outputs and LVCMOS, LVPECL, LVDS, CML, and HCSL receivers, respectively.

#### NOTE

If 1.8-V LVCMOS signals from the high-speed clock outputs are desired to be interfaced with a 3.3-V LVCMOS receiver, a level-shifter like LSF0101 must be used to convert the 1.8-V LVCMOS signal to a 3.3-V LVCMOS signal.

**Figure 63. Interfacing LMK03318's 1.8-V LVCMOS Output With 1.8-V LVCMOS Receiver**

**Figure 64. Interfacing LMK03318's 1.8-V LVCMOS Output With 3.3-V LVCMOS Receiver**

**Figure 65. Interfacing LMK03318's AC-LVPECL Output With LVPECL Receiver**

**Figure 66. Interfacing LMK03318's AC-LVDS Output With LVDS Receiver**

**Figure 67. Interfacing LMK03318's AC-CML Output With CML Receiver**

**Figure 68. Interfacing LMK03318's Output With HCSL Receiver**

### 10.4.17 Output Synchronization

All output dividers and the PLL post divider can be synchronized using the active-low SYNCN signal. This signal can come from the GPIO0 pin (in soft pin mode only) or from R12.6. The most common way to execute the output synchronization is to toggle the GPIO0 pin. When R56.1 is set to 1, to enable synchronization of outputs that is derived from the PLL, and GPIO0 pin is asserted ( $V_{GPIO0} \leq V_{IL}$ ), the corresponding output driver(s) are muted and divider is reset.

#### NOTE

Output-to-output skew specification can only be assured when PLL post divider is greater than 2 and after an output synchronization event.

The latency to reset VCO divider is a sum of:

1. 2 to 3 negative edge of output clock cycles of the largest divided value + “x” nano seconds of asynchronous delay + 2 to 3 VCO clock cycle.
2. If SYNCN happens after rising but before negative edge, sync delay is less 3 clock cycle and closer to 2 clock cycle.
3. The latency is deterministic and its variation is no more than 1 VCO clock cycle and an example scenario is illustrated in [Figure 62](#).

**Table 7. Output Channel Synchronization**

| GPIO0 / R12.6 | OUTPUT DIVIDER AND DRIVER STATE                      |
|---------------|------------------------------------------------------|
| 0             | Output driver(s) is tri-stated and divider is reset  |
| 1             | Normal output driver/divider operation as configured |

Minimum SYNCN pulse width = 3 negative clock edge of slowest output clock cycle + “x” nano second of prop delay + 3 VCO clock cycle. The synchronization feature is particularly helpful in systems with multiple LMK03318 devices. If SYNCN is released simultaneously for all devices, the total remaining output delay variation is  $\pm 1$  VCO clock cycles for all devices configured to identical output mux settings. Output enable/disable events are synchronous to minimize glitch/runt pulses. In Soft Pin Mode, the SYNCN control can also be used to disable any outputs to prevent output clocks from being distributed to down-stream devices, such as DSPs or FPGAs, until they are configured and ready to accept the incoming clock.

**Figure 69. SYNCN to Output Delay Variation**

### 10.4.18 Status Outputs

The device vitals such as input signal quality, smart MUX input selection, PLL loss of lock can be monitored by reading device registers or by monitoring the status pins, STATUS1 and STATUS0. R27 and R28 allow customizing which of the vitals are mapped out to these two pins. [Table 7](#) lists the events that can be mapped to each status pin and which can also be read in the register space. The polarity of the events mapped to the status pins can be selected by programming R15.

A logic-high interrupt output (INTR) can also be selected on either status pins to indicate interrupt status from any of the device vitals listed in R16. To use this feature, R17.0 should be set to 1, R14[4:2] must be set to 0x7, and R14.0 must be set to 1. The interrupts listed in R16 can be combined in an AND or OR functionality by programming R17.1. If interrupts stemming from particular device vitals are to be ignored, the appropriate bits in R14 should be programmed as needed. The contents of R16 can be read back at any time irrespective of whether the INTR function is chosen in either status pins as long as R17.0 = 1 and the contents of R16 are self-cleared once the readback is complete. There also exists a “real-time” interrupt register, R13, which indicate interrupt status from the device vitals irrespective of the state of R17.0. The contents of R13 can be also read back at any time and are self-cleared once the readback is complete.

#### 10.4.18.1 Loss of Reference

The primary and secondary references can be monitored for their input signal quality and appropriate register bits and status outputs, if enabled, are flagged if a *loss of signal* event is encountered. For differential inputs, a “loss of signal” event occurs when the differential input swing is lower than the threshold as programmed in R25[3-2] for secondary reference and in R25[1-0] for primary reference. For LVCMOS inputs, a *loss of signal* event can be triggered based on either a minimum threshold, programmed in R25[3-2] for secondary reference and in R25[1-0] for primary reference, or a minimum slew rate of 0.3 V/ns, rising edge or falling edge or both being monitored based on selections programmed in R25[7-6] for secondary reference and in R25[5-4] for primary reference.

#### 10.4.18.2 Loss of Lock

The PLL’s loss of lock detection circuit is a digital circuit that detects any frequency error, even a single cycle slip. The PLL unlock is detected when a certain number of cycle slips have been exceeded, at which point the counter is reset. If the loss of lock is intended to toggle a system reset, an RC filter on the status output, which is programmed to indicate loss of lock, is recommended to avoid rare cycle slips from triggering an entire system reset.

**Table 8. Device Vitals Selection Matrix for STATUS[1:0]**

| NUMBER | SIGNAL                                                       |
|--------|--------------------------------------------------------------|
| 0      | PRIREF Loss of Signal (LOS)                                  |
| 1      | SECREF Loss of Signal (LOS)                                  |
| 2      | PLL Loss of Lock (LOL)                                       |
| 3      | PLL R Divider, divided by 2 (when R Divider is not bypassed) |
| 4      | PLL N Divider, divided by 2                                  |
| 5      | RESERVED                                                     |
| 6      | RESERVED                                                     |
| 7      | RESERVED                                                     |
| 8      | PLL VCO Calibration Active (CAL)                             |
| 9      | RESERVED                                                     |
| 10     | Interrupt (INTR)                                             |
| 11     | PLL M Divider, divided by 2 (when M Divider is not bypassed) |
| 12     | RESERVED                                                     |
| 13     | EEPROM Active                                                |
| 14     | PLL Secondary to Primary Switch in Automatic Mode            |
| 15     | RESERVED                                                     |

When the status pins are programmed as 3.3-V LVCMOS PLL clock outputs with fast output rise/fall time setting, they support up to 200 MHz operation and each output can independently be programmed to different frequencies. Each output has the option to be muted or not, in case the PLL from which it is derived loses lock, by programming R23 and when muted, the output is held at a static state depending on the programmed output type/polarity. in a loss-of-lock event. To reduce coupling onto the high-speed outputs, the output rise/fall time can be modified in R49 to support slower slew rates.

---

**NOTE**

When either status pin is set as a 3.3-V LVCMOS output, there is fairly significant mixing of these output frequencies into the high-speed outputs, especially outputs 4, 5, 6, and 7. If 3.3-V LVCMOS outputs are desired, proper care should be taken during frequency planning with the LMK03318 to ensure that the outputs, required with low jitter, are selected from either output 0, 1, 2, or 3. For best jitter performance, TI recommends using both status pins to generate complementary 3.3-V LVCMOS outputs at any time.

---

**10.5 Programming**

The host (DSP, Microcontroller, FPGA, etc) configures and monitors the LMK03318 through the I<sup>2</sup>C port. The host reads and writes to a collection of control/status bits called the register map. The device blocks can be controlled and monitored through a specific grouping of bits located within the register file. The host controls and monitors certain device-wide critical parameters directly through register control/status bits. In the absence of the host, the LMK03318 can be configured to operate in pin-mode either from its on-chip ROM or EEPROM depending on the state of HW\_SW\_CTRL pin. The EEPROM or ROM arrays are automatically copied to the device registers upon powerup. The user has the flexibility to re-write the contents of EEPROM from the SRAM up to a 100 times but the contents of ROM cannot be re-written.

Within the device registers, there are certain bits that have read/write access. Other bits are read-only (an attempt to write to a read only bit will not change the state of the bit). Certain device registers and bits are reserved meaning that they must not be changed from their default reset state. [Figure 70](#) shows interface and control blocks within LMK03318 and the arrows refer to read access from and write access to the different embedded memories (ROM, EEPROM, and SRAM).

## Programming (continued)

**Figure 70. LMK03318 Interface and Control Block**

## Programming (continued)

### 10.5.1 I<sup>2</sup>C Serial Interface

The I<sup>2</sup>C port on the LMK03318 works as a slave device and supports both the 100 kHz standard mode and 400 kHz fast-mode operations. Fast mode imposes a glitch tolerance requirement on the control signals. Therefore, the input receivers ignore pulses of less than 50-ns duration. The I<sup>2</sup>C timing is given in *I<sup>2</sup>C-Compatible Interface Characteristics (SDA, SCL)* [I<sup>2</sup>C-Compatible Interface Characteristics \(SDA, SCL\)](#). The timing diagram is given in [Figure 71](#).

**Figure 71. I<sup>2</sup>C Timing Diagram**

In an I<sup>2</sup>C bus system, the LMK03318 acts as a slave device and is connected to the serial bus (data bus SDA and clock bus SCL). These are accessed through a 7-bit slave address transmitted as part of an I<sup>2</sup>C packet. Only the device with a matching slave address responds to subsequent I<sup>2</sup>C commands. In soft pin mode, the LMK03318 allows up to three unique slave devices to occupy the I<sup>2</sup>C bus based on the pin strapping of GPIO1 (tied to VDD\_DIG, GND or V<sub>IM</sub>). The device slave address is 10100xx (the two LSBs are determined by the GPIO1 pin).

#### NOTE

The PDN pin of LMK03318 should be high before any I<sup>2</sup>C communication on the bus. The first I<sup>2</sup>C transaction after power cycling LMK03318 should be ignored.

During the data transfer through the I<sup>2</sup>C interface, one clock pulse is generated for each data bit transferred. The data on the SDA line must be stable during the high period of the clock. The high or low state of the data line can change only when the clock signal on the SCL line is low. The start data transfer condition is characterized by a high-to-low transition on the SDA line while SCL is high. The stop data transfer condition is characterized by a low-to-high transition on the SDA line while SCL is high. The start and stop conditions are always initiated by the master. Every byte on the SDA line must be eight bits long. Each byte must be followed by an acknowledge bit and bytes are sent MSB first. The I<sup>2</sup>C register structure of the LMK03318 is shown in [Figure 72](#).

**Figure 72. I<sup>2</sup>C Register Structure**

## Programming (continued)

The acknowledge bit (A) or non-acknowledge bit (A') is the 9th bit attached to any 8-bit data byte and is always generated by the receiver to inform the transmitter that the byte has been received (when A = 0) or not (when A' = 0). A = 0 is done by pulling the SDA line low during the 9th clock pulse and A' = 0 is done by leaving the SDA line high during the 9th clock pulse.

The I<sup>2</sup>C master initiates the data transfer by asserting a start condition which initiates a response from all slave devices connected to the serial bus. Based on the 8-bit address byte sent by the master over the SDA line (consisting of the 7-bit slave address (MSB first) and an R/W' bit), the device whose address corresponds to the transmitted address responds by sending an acknowledge bit. All other devices on the bus remain idle while the selected device waits for data transfer with the master.

After the data transfer has occurred, stop conditions are established. In write mode, the master asserts a stop condition to end data transfer during the 10th clock pulse following the acknowledge bit for the last data byte from the slave. In read mode, the master receives the last data byte from the slave but does not pull SDA low during the 9th clock pulse. This is known as a non-acknowledge bit. By receiving the non-acknowledge bit, the slave knows the data transfer is finished and enters the idle mode. The master then takes the data line low during the low period before the 10th clock pulse, and high during the 10th clock pulse to assert a stop condition. A generic transaction is shown in [Figure 73](#).

**Figure 73. Generic Programming Sequence**

The LMK03318 I<sup>2</sup>C interface supports “Block Register Write/Read”, “Read/Write SRAM”, and “Read/Write EEPROM” operations. For “Block Register Write/Read” operations, the I<sup>2</sup>C master can individually access addressed registers that are made of an 8-bit data byte. The offset of the indexed register is encoded in R10 and part of the EEPROM, as described in [Table 9](#) below. To change the most significant 5 bits of the I<sup>2</sup>C slave address from its default value, the EEPROM byte 11 can be re-written with the desired value and R10 provides a read-back of the new slave address.

**Table 9. I<sup>2</sup>C Slave Address**

| Operating Mode | R10.7 | R10.6 | R10.5 | R10.4 | R10.3 | R10.2                      | R10.1    |
|----------------|-------|-------|-------|-------|-------|----------------------------|----------|
| Hard pin       | 1     | 0     | 1     | 0     | 0     | 0                          | 0        |
| Soft pin       | 1     | 0     | 1     | 0     | 0     | Controlled by GPIO1 state. |          |
|                |       |       |       |       |       | GPIO1                      | R10[2-1] |
|                |       |       |       |       |       | 0                          | 0x0      |
|                |       |       |       |       |       | V <sub>IM</sub>            | 0x1      |
|                |       |       |       |       |       | 1                          | 0x3      |

### 10.5.2 Block Register Write

The I<sup>2</sup>C *Block Register Write* transaction is illustrated in Figure 74 and consists of the following sequence:

1. Master issues a Start Condition.
2. Master writes the 7-bit Slave Address following by a Write bit.
3. Master writes the 8-bit Register address as the CommandCode of the programming sequence.
4. Master writes one or more Data Bytes each of which should be acknowledged by the slave. The slave increments the internal register address after each byte.
5. Master issues a Stop Condition to terminate the transaction.

**Figure 74. Block Register Write Programming Sequence**

### 10.5.3 Block Register Read

The I<sup>2</sup>C *Block Register Read* transaction is illustrated in Figure 75 and consists of the following sequence:

1. Master issues a Start Condition.
2. Master writes the 7-bit Slave Address followed by a Write bit.
3. Master writes the 8-bit Register address as the CommandCode of the programming sequence.
4. Master issues a Repeated Start Condition.
5. Master writes the 7-bit Slave Address following by a Read bit.
6. Slave returns one or more Data Bytes as long as the Master continues to acknowledge them. The slave increments the internal register address after each byte.
7. Master issues a Stop Condition to terminate the transaction.

**Figure 75. Block Register Read Programming Sequence**

### 10.5.4 Write SRAM

The on-chip SRAM is a volatile, shadow memory array used to temporarily store register data, and is intended only for programming the non Volatile EEPROM array with one or more device start-up configuration settings (pages). The SRAM has the identical data format as the EEPROM map. The register configuration data can be transferred to the SRAM array through special memory access registers in the register map.

The SRAM is made up of a base memory array and 6 pages of identical memory arrays. To successfully program the SRAM, the complete base array and at least one page should be written.

The following details the programming sequence to transfer the device registers into the appropriate SRAM page.

1. Program the device registers to match a desired setting.
2. Write R145[3:0] with a valid SRAM page (0 to 5) to commit the current register data.
3. Write a 1 to R137.6. This ensures that the device registers are copied to the desired SRAM page.
4. If another device setting is desired to be written to a different SRAM page, repeat steps 1-3 and select an unused SRAM page.

The SRAM can also be written with particular values according to the following programming sequence.

1. Write the most significant 8th bit of the SRAM address in R139.0 and write the least significant 8 bits in R140.
2. Write the desired data byte in R142 in the same I<sup>2</sup>C transaction and this data byte will be written to the address specified in the step above. Any additional access that is part of the same transaction will cause the SRAM address to be incremented and a write will take place to the next SRAM address. Access to SRAM will terminate at the end of current I<sup>2</sup>C transaction.
3. Steps 1 and 2 need to be followed to change EEPROM bytes 11 and 12. Byte 11 denotes the I<sup>2</sup>C slave address of LMK03318 and Byte 12 denotes an 8-b user space that can be used as a device identifier among multiple LMK03318 instances with different EEPROM images.

---

#### NOTE

It is possible to increment SRAM address incorrectly when 2 successive accesses are made to R140.

---

### 10.5.5 Write EEPROM

The on-chip EEPROM is a non-volatile memory array used to permanently store register data for one or more device start-up configuration settings (pages), which can be selected to initialize registers upon power-up or POR. There are a total of 6 independent EEPROM pages of which each page is selected by the 3-level GPIO[3:2] pins, and each page is comprised of bits shown in the [EEPROM Map](#). The transfer must first happen to the corresponding SRAM page and then to the EEPROM page. During “EEPROM write”, R137.2 is a 1 and the EEPROM contents cannot be accessed. The following details the programming sequence to transfer the entire contents of SRAM to EEPROM:

1. Make sure the *Write SRAM* procedure ([Write SRAM](#)) was done to commit the register settings to the SRAM page(s) with start-up configurations intended for programming to the EEPROM array.
2. Write 0xEA to R144. This provides basic protection from inadvertent programming of EEPROM.
3. Write a 1 to R137.0. This programs the entire SRAM contents to EEPROM. Once completed, the contents in R136 will increment by 1. R136 contains the total number of EEPROM programming cycles that are successfully completed.
4. Write 0x00 to R144 to protect against inadvertent programming of EEPROM.
5. If an EEPROM write is unsuccessful, a readback of R137.5 results in a 1. In this case, the device will not function correctly and will be locked up. To unlock the device for correct operation, a new EEPROM write sequence should be initiated and successfully completed.

### 10.5.6 Read SRAM

The contents of the SRAM can be read out, one word at a time, starting with that of the requested address. The following details the programming sequence for an SRAM read by address.

1. Write the most significant 9th bit of the SRAM address in R139.0 and write the least significant 8 bits of the SRAM address in R140.
2. The SRAM data located at the address specified in the step above can be obtained by reading R142 in the same I<sup>2</sup>C transaction. Any additional access that is part of the same transaction will cause the SRAM address to be incremented and a read will take place of the next SRAM address. Access to SRAM will terminate at the end of current I<sup>2</sup>C transaction.

---

#### NOTE

It is possible to increment SRAM address incorrectly when 2 successive accesses are made to R140.

---

### 10.5.7 Read EEPROM

The contents of the EEPROM can be read out, one word at a time, starting with that of the requested address. The following details the programming sequence for an EEPROM read by address.

1. Write the most significant 9th bit of the EEPROM address in R139.0 and write the least significant 8 bits of the EEPROM address in R140.
2. The EEPROM data located at the address specified in the step above can be obtained by reading R141 in the same I<sup>2</sup>C transaction. Any additional access that is part of the same transaction will cause the EEPROM address to be incremented and a read will take place of the next EEPROM address. Access to EEPROM will terminate at the end of current I<sup>2</sup>C transaction.

---

#### NOTE

It is possible to increment EEPROM address incorrectly when 2 successive accesses are made to R140.

---

### 10.5.8 Read ROM

The contents of the ROM can be read out, one word at a time, starting with that of the requested address. The following details the programming sequence of a ROM read by address.

1. Write the most significant 11th, 10th, 9th, and 8th bit of the ROM address in R139[3-0] and write the least significant 8 bits of the ROM address in R140.
2. The ROM data located at the address specified in the step above can be obtained by reading R143 in the same I<sup>2</sup>C transaction. Any additional access that is part of the same transaction will cause the ROM address to be incremented and a read will take place of the next ROM address. Access to ROM will terminate at the end of current I<sup>2</sup>C transaction.

### 10.5.9 Default Device Configurations in EEPROM and ROM

Table 10 through Table 13 show the device default configurations stored in the on-chip EEPROM. Table 14 through Table 18 show the device default configurations stored in the on-chip ROM.

**Table 10. Default EEPROM Contents (HW\_SW\_CTRL = 0) – Input and Status Configuration<sup>(1)(2)</sup>**

(1) When PLL is set as an integer-based clock generator, external loop filter component, C2, should be 3.3nF and loop bandwidth is around 400kHz. When PLL is set as a fractional-based clock generator, external loop filter component, C2, should be 33nF and loop bandwidth is around 400kHz.

## 10.6 Register Maps

The register map is shown in the table below. The registers occupy a single unified address space and all registers are accessible at any time. A total of 103 registers are present in the LMK03318.

| Name         | Address | Reset | Bit7                   | Bit6                | Bit5                       | Bit4                       | Bit3              | Bit2              | Bit1               | Bit0               |
|--------------|---------|-------|------------------------|---------------------|----------------------------|----------------------------|-------------------|-------------------|--------------------|--------------------|

## LMK03318

JAJSFA5E –SEPTEMBER 2015–REVISED APRIL 2018

www.ti.com

### 10.6.1 VNDRID\_BY1 Register; R0

The VNDRID\_BY1 and VNDRID\_BY0 registers are used to store the unique 16-bit Vendor Identification number assigned to I<sup>2</sup>C vendors.

| Bit # | Field        | Type | Reset | EEPROM | Description                                                                                                                                          |
|-------|--------------|------|-------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | VNDRID[15:8] | R    | 0x10  | N      | Vendor Identification Number Byte 1. The Vendor Identification Number is a unique 16-bit identification number assigned to I <sup>2</sup> C vendors. |

### 10.6.2 VNDRID\_BY0 Register; R1

The VNDRID\_BY0 register is described in the following table.

| Bit # | Field       | Type | Reset | EEPROM | Description                          |
|-------|-------------|------|-------|--------|--------------------------------------|
| [7:0] | VNDRID[7:0] | R    | 0x0B  | N      | Vendor Identification Number Byte 0. |

### 10.6.3 PRODID Register; R2

The PRODID register is used to identify the LMK03318 device.

| Bit # | Field       | Type | Reset | EEPROM | Description                                                                                                                             |
|-------|-------------|------|-------|--------|-----------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | PRODID[7:0] | R    | 0x33  | N      | Product Identification Number. The Product Identification Number is a unique 8-bit identification number used to identify the LMK03318. |

### 10.6.4 REVID Register; R3

The REVID register is used to identify the LMK03318 mask revision.

| Bit # | Field      | Type | Reset | EEPROM | Description                                                                                      |
|-------|------------|------|-------|--------|--------------------------------------------------------------------------------------------------|
| [7:0] | REVID[7:0] | R    | 0x02  | N      | Device Revision Number. The Device Revision Number is used to identify the LMK03318 die revision |

### 10.6.5 PARTID Register; R4

Each LMK03318 device can be identified by a unique 8-bit number stored in the PARTID register. This register is always initialized from on-chip EEPROM.

| Bit # | Field      | Type | Reset | EEPROM | Description                                                                                                                                                                                                                          |
|-------|------------|------|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | PRTID[7:0] | R    | 0x01  | Y      | Part Identification Number. The Part Identification Number is a unique 8-bit number which is used to serialize individual LMK03318 devices. The Part Identification Number is factory programmed and cannot be modified by the user. |

### 10.6.6 PINMODE\_SW Register; R8

The PINMODE\_SW register records the device configuration setting. The configuration setting is registered when the reset is deasserted.

| Bit # | Field               | Type | Reset | EEPROM | Description                                                                                                                                                                                                      |
|-------|---------------------|------|-------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7]   | HW_SW_CTRL_MODE     | R    | 0     | N      | HW_SW_CTRL Pin Configuration. The HW_SW_CTRL_MODE field reflects the values sampled on the HW_SW_CTRL pin on the most recent device reset.                                                                       |
|       |                     |      |       |        | HW_SW_CTRL_MODE      HW_SW_CTRL                                                                                                                                                                                  |
|       |                     |      |       |        | 0      Soft Pin Mode                                                                                                                                                                                             |

### 10.6.9 EEREV Register; R11

The EEREV register provides EEPROM/ROM image revision record and is initialized from EEPROM or ROM.

| Bit # | Field      | Type | Reset | EEPROM | Description                                                                                                                                                               |
|-------|------------|------|-------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | EEREV[7:0] | R    | 0x0   | Y      | EEPROM Image Revision ID. EEPROM Image Revision is automatically retrieved from EEPROM and stored in the EEREV register after a reset or after a EEPROM commit operation. |

### 10.6.10 DEV\_CTL Register; R12

The DEV\_CTL register holds the control functions described in the following table.

| Bit # | Field        | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                                                                                                           |                                     |
|-------|--------------|------|-------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| [7]   | RESETN_SW    | RW   | 1     | N      | Software Reset ALL functions (active low). Writing a 0 will cause the device to return to its power-up state apart from the I <sup>2</sup> C registers and the configuration controller. The configuration controller is excluded to prevent a re-transfer of EEPROM data to on-chip registers.                                                                                                       |                                     |
| [6]   | SYNCRN_SW    | RW   | 1     | N      | Software SYNC Assertion (active low). Writing a 0 to this bit is equivalent to asserting the GPIO0 pin.                                                                                                                                                                                                                                                                                               |                                     |
| [5]   | RSRVD        | -    | -     | N      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                             |                                     |
| [4]   | SYNC_AUTO    | RW   | 1     | Y      | Automatic Synchronization at startup. When SYNC_AUTO is 1 at device startup a synchronization sequence is initiated automatically after PLL lock has been achieved.                                                                                                                                                                                                                                   |                                     |
| [3]   | SYNC_MUTE    | RW   | 1     | Y      | Synchronization Mute Control. The SYNC_MUTE field determines whether or not the output drivers are muted during a Synchronization event.                                                                                                                                                                                                                                                              |                                     |
|       |              |      |       |        | SYNC_MUTE                                                                                                                                                                                                                                                                                                                                                                                             | SYNC Mute Behaviour                 |
|       |              |      |       |        | 0                                                                                                                                                                                                                                                                                                                                                                                                     | Do not mute any outputs during SYNC |
|       |              |      |       |        | 1                                                                                                                                                                                                                                                                                                                                                                                                     | Mute all outputs during SYNC        |
| [2]   | AONAFTERLOCK | RW   | 0     | Y      | Always On Clock behaviour after Lock. If AONAFTERLOCK is 0 then the system clock is switched from the Always On Clock to the VCO Clock after lock and the Always On Clock oscillator is disabled. If AONAFTERLOCK is 1 then the Always on Clock will remain as the digital system clock regardless of the PLL Lock state. TI recommends setting the AONAFTERLOCK to 1.                                |                                     |
| [1]   | RSRVD        | RW   | 0     | Y      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                             |                                     |
| [0]   | AUTOSTRT     | RW   | 1     | Y      | Autostart. If AUTOSTRT is set to 1 the device will automatically attempt to achieve lock and enable outputs after a device reset. A device reset can be triggered by the power-on-reset, RESETn pin or by writing to the RESETN_SW bit. If AUTOSTRT is 0 then the device will halt after the configuration phase, a subsequent write to set the AUTOSTRT bit to 1 will trigger the PLL Lock sequence. |                                     |

### 10.6.11 INT\_LIVE Register; R13

The INT\_LIVE register reflects the current status of the interrupt sources, regardless of the state of the INT\_EN bit.

| Bit # | Field    | Type | Reset | EEPROM | Description                                                                                                                                                   |
|-------|----------|------|-------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7]   | LOL      | R    | 0     | N      | Loss of lock on PLL.                                                                                                                                          |
| [6]   | LOS      | R    | 0     | N      | Loss of input signal to PLL. If input signal to PLL is lost and as a result PLL is unlocked, LOS will take precedence over LOL and only LOS will be set to 1. |
| [5]   | CAL      | R    | 0     | N      | VCO calibration active on PLL.                                                                                                                                |
| [4:2] | RSRVD    | -    | -     | N      | Reserved.                                                                                                                                                     |
| [1]   | SECTOPRI | R    | 0     | N      | Switch from secondary reference to primary reference in automatic mode for PLL.                                                                               |
| [0]   | RSRVD    | -    | -     | N      | Reserved.                                                                                                                                                     |

### 10.6.12 INT\_MASK Register; R14

The INT\_MASK register allows masking of the interrupt sources.

| Bit # | Field         | Type | Reset | EEPROM | Description                                                                                                                                                                                      |
|-------|---------------|------|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7]   | LOL_MASK      | RW   | 0     | Y      | Mask loss of lock on PLL. When LOL_MASK is 1 then the LOL interrupt source is masked and will not cause the interrupt signal to be activated.                                                    |
| [6]   | LOS_MASK      | RW   | 0     | Y      | Mask loss of input signal to PLL. When LOS_MASK is 1 then the LOS interrupt source is masked and will not cause the interrupt signal to be activated.                                            |
| [5]   | CAL_MASK      | RW   | 0     | Y      | Mask VCO calibration active on PLL. When CAL_MASK is 1 then the CAL interrupt source is masked and will not cause the interrupt signal to be activated.                                          |
| [4:2] | RSRVD         | RW   | 0     | Y      | Reserved.                                                                                                                                                                                        |
| [1]   | SECTOPRI_MASK | RW   | 0     | Y      | Mask switch from secondary reference to primary reference for PLL. When SECTOPRI_MASK is 1 then the SECTOPRI interrupt source is masked and will not cause the interrupt signal to be activated. |
| [0]   | RSRVD         | RW   | 0     | Y      | Reserved.                                                                                                                                                                                        |

### 10.6.13 INT\_FLAG\_POL Register; R15

The INT\_FLAG\_POL register controls the signal polarity that sets the Interrupt Flags.

| Bit # | Field        | Type | Reset | EEPROM | Description                                                                                                                                                                                                                         |
|-------|--------------|------|-------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7]   | LOL_POL      | RW   | 0     | Y      | LOL Flag Polarity. When LOL_POL is 1 then a rising edge on LOL will set the LOL_INTR bit of the INTERRUPT_FLAG register. When LOL_POL is 0 then a falling edge on LOL will set the LOL_INTR bit.                                    |
| [6]   | LOS_POL      | RW   | 0     | Y      | LOS Flag Polarity. When LOS_POL is 1 then a rising edge on LOS will set the LOS_INTR bit of the INTERRUPT_FLAG register. When LOS_POL is 0 then a falling edge on LOS will set the LOS_INTR bit.                                    |
| [5]   | CAL_POL      | RW   | 0     | Y      | CAL Flag Polarity. When CAL_POL is 1 then a rising edge on CAL will set the CAL_INTR bit of the INTERRUPT_FLAG register. When CAL_POL is 0 then a falling edge on CAL1 will set the CAL_INTR bit.                                   |
| [4:2] | RSRVD        | RW   | 0     | Y      | Reserved.                                                                                                                                                                                                                           |
| [1]   | SECTOPRI_POL | RW   | 0     | Y      | SECTOPRI Flag Polarity. When SECTOPRI_POL is 1 then a rising edge on SECTOPRI will set the SECTOPRI_INTR bit of the INTERRUPT_FLAG register. When SECTOPRI_POL is 0 then a falling edge on SECTOPRI will set the SECTOPRI_INTR bit. |
| [0]   | RSRVD        | RW   | 0     | Y      | Reserved.                                                                                                                                                                                                                           |

### 10.6.14 INT\_FLAG Register; R16

The INT\_FLAG register records rising or falling edges on the interrupt sources. The polarity is controlled by the INT\_FLAG\_POL register. This register is only updated if the INT\_EN register bit is set to 1.

| Bit # | Field         | Type | Reset | EEPROM | Description                                                                                                                                                                          |
|-------|---------------|------|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7]   | LOL_INTR      | R    | 0     | N      | LOL Interrupt. The LOL_INTR bit is set when an edge of the correct polarity is detected on the LOL interrupt source. The LOL_INTR bit is cleared by writing a 0.                     |
| [6]   | LOS_INTR      | R    | 0     | N      | LOS Interrupt. The LOS_INTR bit is set when an edge of the correct polarity is detected on the LOS interrupt source. The LOS_INTR bit is cleared by writing a 0.                     |
| [5]   | CAL_INTR      | R    | 0     | N      | CAL Interrupt. The CAL_INTR bit is set when an edge of the correct polarity is detected on the CAL interrupt source. The CAL_INTR bit is cleared by writing a 0.                     |
| [4:2] | RSRVD         | R    | 0     | N      | Reserved.                                                                                                                                                                            |
| [1]   | SECTOPRI_INTR | R    | 0     | N      | SECTOPRI Interrupt. The SECTOPRI_INTR bit is set when an edge of the correct polarity is detected on the SECTOPRI interrupt source. The SECTOPRI_INTR bit is cleared by writing a 0. |
| [0]   | RSRVD         | R    | 0     | N      | Reserved.                                                                                                                                                                            |

**10.6.15 INTCTL Register; R17**

The INTCTL register allows configuration of the Interrupt operation.

| Bit # | Field      | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                                                         |
|-------|------------|------|-------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:2] | RSRVD      | -    | -     | N      | Reserved.                                                                                                                                                                                                                                                                                                                                           |
| [1]   | INT_AND_OR | RW   | 0     | Y      | Interrupt AND/OR Combination. If INT_AND_OR is 1 then the interrupts are combined in an AND structure. In which case ALL un mAsked interrupt flags must be active to generate the interrupt. If INT_AND_OR is 0 then the interrupts are combined in an OR structure. In which case ANY un mAsked interrupt flags can generate the interrupt         |
|       | INT_AND_OR |      |       |        | Interrupt Function                                                                                                                                                                                                                                                                                                                                  |
|       | 0          |      |       |        | OR                                                                                                                                                                                                                                                                                                                                                  |
|       | 1          |      |       |        | AND                                                                                                                                                                                                                                                                                                                                                 |
| [0]   | INT_EN     | RW   | 0     | Y      | Interrupt Enable. If INT_EN is 1 then the interrupt circuit is enabled, if INT_EN is 0 the interrupt circuit is disabled. When INT_EN is 0, interrupts cannot be signalled on the STATUS pins and the INT_FLAG registers will not be updated, however the INT_LIVE register will still reflect the current state of the internal interrupt signals. |

**10.6.16 OSCCTL2 Register; R18**

The OSCCTL2 register provides access to input reference status signals

| Bit # | Field          | Type | Reset | EEPROM | Description                                                      |
|-------|----------------|------|-------|--------|------------------------------------------------------------------|
| [7]   | RISE_VALID_SEC | R    | 0     | N      | Secondary Input Rising Valid Indicator from Slew Rate Detector.  |
| [6]   | FALL_VALID_SEC | R    | 0     | N      | Secondary Input Falling Valid Indicator from Slew Rate Detector. |
| [5]   | RISE_VALID_PRI | R    | 0     | N      | Primary Input Rising Valid Indicator from Slew Rate Detector.    |
| [4]   | FALL_VALID_PRI | R    | 0     | N      | Primary Input Falling Valid Indicator from Slew Rate Detector.   |
| [3:0] | RSRVD          | -    | -     | N      | Reserved.                                                        |

**10.6.17 STATCTL Register; R19**

The STATCTL register provides to STATUS0/1 output driver control signals.

| Bit # | Field                  | Type | Reset | EEPROM | Description                                                                                                                                                                                   |
|-------|------------------------|------|-------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:6] | RSRVD                  | -    | -     | N      | Reserved.                                                                                                                                                                                     |
| [5]   | STAT1_SHOOT_THRU_LIMIT | RW   | 0     | Y      | STATUS1 Output Shoot Through Current Limit. When STAT1_SHOOT_THRU_LIMIT is 1 then the transient current spikes are minimized, the performance of the STATUS1 output is degraded in this mode. |
| [4]   | STAT0_SHOOT_THRU_LIMIT | RW   | 0     | Y      | STATUS0 Output Shoot Through Current Limit. When STAT0_SHOOT_THRU_LIMIT is 1 then the transient current spikes are minimized, the performance of the STATUS0 output is degraded in this mode. |
| [3:2] | RSRVD                  | RW   | 0x0   | Y      | Reserved.                                                                                                                                                                                     |
| [1]   | STAT1_OPEND            | RW   | 0     | Y      | STATUS1 Open Drain Enable. When STAT1_OPEND is 1 the STATUS1 output is configured as an open drain output driver.                                                                             |
| [0]   | STAT0_OPEND            | RW   | 0     | Y      | STATUS0 Open Drain Enable. When STAT0_OPEND is 1 the STATUS0 output is configured as an open drain output driver.                                                                             |

### 10.6.18 MUTELVL1 Register; R20

The MUTELVL1 register determines the Output Driver during mute for output drivers 0 to 3.

| Bit # | Field                 | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                               |
|-------|-----------------------|------|-------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:6] | CH3_MUTE_LVL<br>[1:0] | RW   | 0x1   | Y      | Channel 3 Output Driver Mute Level. CH3_MUTE_LVL determines the configuration of the CH3 Output Driver during mute as shown in the following table and is recommended to be set to 0x3. CH3_MUTE_LVL does not determine whether the CH3 driver is muted or not, instead this is determined by the CH_3_MUTE register bit. |
|       |                       |      |       |        | CH3_MUTE_LVL      DIFF MODE      CMOS MODE                                                                                                                                                                                                                                                                                |
|       |                       |      |       |        | 0 (0x0)      CH3 Mute Bypass      CH3 Mute Bypass                                                                                                                                                                                                                                                                         |
|       |                       |      |       |        | 1 (0x1)      Powerdown, output goes to Vcm      Out_P Normal Operation, Out_N Force Output Low                                                                                                                                                                                                                            |
|       |                       |      |       |        | 2 (0x2)      Force output High      Out_P Force Output Low, Out_N Normal Operation                                                                                                                                                                                                                                        |
|       |                       |      |       |        | 3 (0x3)      Force the positive output node to the internal regulator output voltage rail (when AC coupled to load) and the negative output node to the GND rail      Out_P Force Output Low, Out_N Force Output Low                                                                                                      |
| [5:4] | CH2_MUTE_LVL<br>[1:0] | RW   | 0x1   | Y      | Channel 2 Output Driver Mute Level. CH2_MUTE_LVL determines the configuration of the CH2 Output Driver during mute as shown in the following table and is recommended to be set to 0x3. CH2_MUTE_LVL does not determine whether the CH2 driver is muted or not, instead this is determined by the CH_2_MUTE register bit. |

**10.6.19 MUTELVL2 Register; R21**

The MUTELVL2 register determines the Output Driver during mute for output drivers 4 to 7.

| Bit # | Field                 | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                               |

## 10.6.20 OUT\_MUTE Register; R22

### Output Channel Mute Control

| Bit # | Field     | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                             |
|-------|-----------|------|-------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7]   | CH_7_MUTE | RW   | 1     | Y      | Channel 7 Mute Control. When CH_7_MUTE is set to 1 Output Channel 7 is automatically disabled when the selected clock source is invalid. When CH_7_MUTE_7 is 0 Channel 7 will continue to operate regardless of the state of the selected clock source. |
| [6]   | CH_6_MUTE | RW   | 1     | Y      | Channel 6 Mute Control. When CH_6_MUTE is set to 1 Output Channel 6 is automatically disabled when the selected clock source is invalid. When CH_6_MUTE_6 is 0 Channel 6 will continue to operate regardless of the state of the selected clock source. |
| [5]   | CH_5_MUTE | RW   | 1     | Y      | Channel 5 Mute Control. When CH_5_MUTE is set to 1 Output Channel 5 is automatically disabled when the selected clock source is invalid. When CH_5_MUTE_5 is 0 Channel 5 will continue to operate regardless of the state of the selected clock source. |
| [4]   | CH_4_MUTE | RW   | 1     | Y      | Channel 4 Mute Control. When CH_4_MUTE is set to 1 Output Channel 4 is automatically disabled when the selected clock source is invalid. When CH_4_MUTE_4 is 0 Channel 4 will continue to operate regardless of the state of the selected clock source. |
| [3]   | CH_3_MUTE | RW   | 1     | Y      | Channel 3 Mute Control. When CH_3_MUTE is set to 1 Output Channel 3 is automatically disabled when the selected clock source is invalid. When CH_3_MUTE is 0 Channel 3 will continue to operate regardless of the state of the selected clock source.   |
| [2]   | CH_2_MUTE | RW   | 1     | Y      | Channel 2 Mute Control. When CH_2_MUTE is set to 1 Output Channel 2 is automatically disabled when the selected clock source is invalid. When CH_2_MUTE is 0 Channel 2 will continue to operate regardless of the state of the selected clock source.   |
| [1]   | CH_1_MUTE | RW   | 1     | Y      | Channel 1 Mute Control. When CH_1_MUTE is set to 1 Output Channel 1 is automatically disabled when the selected clock source is invalid. When CH_1_MUTE is 0 Channel 1 will continue to operate regardless of the state of the selected clock source.   |
| [0]   | CH_0_MUTE | RW   | 1     | Y      | Channel 0 Mute Control. When CH_0_MUTE is set to 1 Output Channel 0 is automatically disabled when the selected clock source is invalid. When CH_0_MUTE is 0 Channel 0 will continue to operate regardless of the state of the selected clock source.   |

## 10.6.21 STATUS\_MUTE Register; R23

### Status CMOS Output Mute Control

| Bit # | Field        | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|--------------|------|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:2] | RSRVD        | -    | -     | N      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| [1]   | STATUS1_MUTE | RW   | 1     | Y      | STATUS1 Mute Control. When the STATUS1 output is configured to provide a CMOS Clock and the STATUS1_MUTE bit is set to 1 then the STATUS1 Output is automatically disabled when the selected clock source is invalid. When STATUS1_MUTE is 0 the STATUS1 Output will continue to operate regardless of the state of the selected clock source. If the STATUS1 output is not configured to provide a Clock then it will continue to operate regardless of the STATUS1_MUTE bit value. |
| [0]   | STATUS0_MUTE | RW   | 0     | Y      | STATUS0 Mute Control. When the STATUS0 output is configured to provide a CMOS Clock and the STATUS0_MUTE bit is set to 1 then the STATUS0 Output is automatically disabled when the selected clock source is invalid. When STATUS0_MUTE is 0 the STATUS0 Output will continue to operate regardless of the state of the selected clock source. If the STATUS0 output is not configured to provide a Clock then it will continue to operate regardless of the STATUS0_MUTE bit value. |

## 10.6.22 DYN\_DLY Register; R24

### Output Divider Dynamic Delay Control

### 10.6.23 REFDECTL Register; R25

The REFDECTL register provides control over input reference clock detect features.

| [7:6] | DETECT_MODE_SEC[1:0] | RW   | 0x1   | Y      | Secondary Input Energy Detector Mode Control. The DETECT_MODE_SEC field determines the method for Energy Detection on a single-ended signal on the Secondary Input as follows. When rising and/or falling slew rate detector is enabled, the reference input should meet the following conditions for correct operation: $V_{IH} < 1.7\text{ V}$ and $V_{IL} > 0.2\text{ V}$ . When VIH/VIL level detector is enabled, the reference input should meet the following conditions for correct operation: $V_{IH} < 1.5\text{ V}$ and $V_{IL} > 0.4\text{ V}$ . |                                       |

### 10.6.24 STAT0\_INT Register; R27

The STAT0\_INT register provides control of the STATUS0 output and Interrupt configuration. The STATUS0 pin is also used for test and diagnostic functions. The test configuration registers override the STAT0\_INT register.

**10.6.25 STAT1 Register; R28**

The STAT1\_INT register provides control of the STATUS1 output. The STATUS1 pin is also used for test and diagnostic functions. The test configuration registers override the STAT0 register.

### 10.6.26 OSCCTL1 Register; R29

The OSCCTL1 register provides control over input reference clock features.

| Bit # | Field        | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                 |
|-------|--------------|------|-------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7]   | DETECT_BYP   | RW   | 0     | Y      | Signal Detector Bypass. When DETECT_BYP is 1 the output of the Signal Detector's, both Primary and Secondary are ignored and the inputs are always considered to be valid by the PLL control state machines. The DETECT_BYP bit has no effect on the Interrupt register or STATUS output's. |
| [6]   | RSRVD        | -    | -     | N      | Reserved.                                                                                                                                                                                                                                                                                   |
| [5]   | TERM2GND_SEC | RW   | 0     | Y      | Differential Termination to GND Control for Secondary Input. When TERM2GND_SEC is 1 an internal 50 $\Omega$ termination to GND is selected on the Secondary input in differential mode.                                                                                                     |
| [4]   | TERM2GND_PRI | RW   | 0     | Y      | Differential Termination to GND Control for Primary Input. When TERM2GND_PRI is 1 an internal 50 $\Omega$ termination to GND is selected on the Primary input in differential mode.                                                                                                         |
| [3]   | DIFFTERM_SEC | RW   | 0     | Y      | Differential Termination Control for Secondary Input. When DIFFTERM_SEC is 1 an internal 100 $\Omega$ termination is selected on the Secondary input in differential mode.                                                                                                                  |
| [2]   | DIFFTERM_PRI | RW   | 1     | Y      | Differential Termination Control for Primary Input. When DIFFTERM_PRI is 1 an internal 100 $\Omega$ termination is selected on the Primary input in differential mode.                                                                                                                      |
| [1]   | AC_MODE_SEC  | RW   | 1     | Y      | AC Coupling Mode for Secondary Input. When AC_MODE_SEC is 1, this enables the internal input biasing to support an externally AC coupled input signal on the SECREF inputs. When AC_MODE_SEC is 0, the internal input bias is not used.                                                     |
| [0]   | AC_MODE_PRI  | RW   | 0     | Y      | AC Coupling Mode for Primary Input. When AC_MODE_PRI is 1, this enables the internal input biasing to support an externally AC coupled input signal on the PRIREF inputs. When AC_MODE_PRI is 0, the internal input bias is not used.                                                       |

### 10.6.27 PWDN Register; R30

The PWDN register is described in the following table.

| Bit # | Field      | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                      |
|-------|------------|------|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7]   | RSRVD      | -    | -     | N      | Reserved.                                                                                                                                                                                                                                        |
| [6]   | CMOSCHPWDN | RW   | 0     | Y      | CMOS Output Channel Powerdown.                                                                                                                                                                                                                   |
| [5]   | CH7PWDN    | RW   | 0     | Y      | Output Channel 7 Powerdown. When CH7PWDN is 1, the MUX and divider of channel 7 will be disabled. To shut down entire output path (output MUX, divider and buffer), R43[5:4] should be set to 0x0 irrespective of R30.5.                         |
| [4]   | CH6PWDN    | RW   | 0     | Y      | Output Channel 6 Powerdown. When CH6PWDN is 1, the MUX and divider of channel 6 will be disabled. To shut down entire output path (output MUX, divider and buffer), R41[5:4] should be set to 0x0 irrespective of R30.4.                         |
| [3]   | CH5PWDN    | RW   | 0     | Y      | Output Channel 5 Powerdown. When CH5PWDN is 1, the MUX and divider of channel 5 will be disabled. To shut down entire output path (output MUX, divider and buffer), R39[5:4] should be set to 0x0 irrespective of R30.3.                         |
| [2]   | CH4PWDN    | RW   | 0     | Y      | Output Channel 4 Powerdown. When CH4PWDN is 1, the MUX and divider of channel 4 will be disabled. To shut down entire output path (output MUX, divider and buffer), R37[5:4] should be set to 0x0 irrespective of R30.2.                         |
| [1]   | CH23PWDN   | RW   | 0     | Y      | Output Channel 23 Powerdown. When CH23PWDN is 1, the MUX and divider of channels 2 and 3 will be disabled. To shut down entire output paths (output MUX, divider and buffers), R35[6:5] and R34[6:5] should be set to 0x0 irrespective of R30.1. |
| [0]   | CH01PWDN   | RW   | 0     | Y      | Output Channel 01 Powerdown. When CH01PWDN is 1, the MUX and divider of channels 0 and 1 will be disabled. To shut down entire output paths (output MUX, divider and buffers), R32[6:5] and R31[6:5] should be set to 0x0 irrespective of R30.0. |

### 10.6.28 OUTCTL\_0 Register; R31

The OUTCTL\_0 register provides control over Output 0.

| Bit # | Field            | Type | Reset | EEPROM | Description                                                                                                     |
|-------|------------------|------|-------|--------|-----------------------------------------------------------------------------------------------------------------|
| [7]   | RSRVD            | RW   | 1     | Y      | Reserved. TI recommends setting it to "0".                                                                      |
| [6:5] | OUT_0_SEL[1:0]   | RW   | 0x1   | Y      | Channel 0 Output Driver Format Select. The OUT_0_SEL field controls the Channel 0 Output Driver as shown below. |
|       | OUT_0_SEL        |      |       |        | OUTPUT OPERATION                                                                                                |
|       | 0 (0x0)          |      |       |        | Disabled                                                                                                        |
|       | 1 (0x1)          |      |       |        | AC-LVDS/AC-CML/AC-LVPECL                                                                                        |

### 10.6.34 OUTCTL\_4 Register; R37

The OUTCTL\_4 register provides control over Output 4

| Bit # | Field            | Type | Reset | EEPROM | Description                                                                                                                                                                                                       |

### 10.6.35 OUTDIV\_4 Register; R38

Channel 4 Output Divider

| Bit # | Field          | Type | Reset | EEPROM | Description                                                                                                                                                                                                                     |
|-------|----------------|------|-------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | OUT_4_DIV[7:0] | RW   | 0x02  | Y      | Channel 4 Output Divider. The Channel 4 Divider, OUT_4_DIV, is a 8-bit divider. The valid values for OUT_4_DIV range from 1 to 256 as shown below. The divider only operates on Channel 4 when the clock source is PLL or PLL2. |

**10.6.37 OUTDIV\_5 Register; R40**

Channel 5 Output Divider

| Bit # | Field          | Type | Reset | EEPROM | Description                                                                                                                                                                                                                     |
|-------|----------------|------|-------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | OUT_5_DIV[7:0] | RW   | 0x02  | Y      | Channel 5 Output Divider. The Channel 5 Divider, OUT_5_DIV, is a 8-bit divider. The valid values for OUT_5_DIV range from 1 to 256 as shown below. The divider only operates on Channel 5 when the clock source is PLL or PLL2. |
|       |                |      |       |        | OUT_5_DIV                                                                                                                                                                                                                       |

### 10.6.38 OUTCTL\_6 Register; R41

The OUTCTL\_6 register provides control over Output 6.

| Bit # | Field            | Type | Reset | EEPROM | Description                                                                                                                                                                                                       |

Channel 6 Output Divider

| Bit # | Field          | Type | Reset | EEPROM | Description                                                                                                                                                                                                                     |
|-------|----------------|------|-------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | OUT_6_DIV[7:0] | RW   | 0x05  | Y      | Channel 6 Output Divider. The Channel 6 Divider, OUT_6_DIV, is a 8-bit divider. The valid values for OUT_6_DIV range from 1 to 256 as shown below. The divider only operates on Channel 6 when the clock source is PLL or PLL2. |

### 10.6.40 OUTCTL\_7 Register; R43

The OUTCTL\_7 register provides control over Output 7.

| Bit # | Field            | Type | Reset | EEPROM | Description                                                                                                                                                                                                       |

### 10.6.42 CMOSDIVCTRL Register; R45

CMOS Output Divider Control. The CMOS Clock Outputs provided on STATUS0 and STATUS1 can come from either CMOS Divider0 or CMOS Divider1. Additionally the clock source routed to the CMOS Dividers can come from either the PLL LVCMOS Pre-Divider or the PLL2 LVCMOS Pre-Divider.

| Bit # | Field              | Type | Reset | EEPROM | Description                                                                                                                                |
|-------|--------------------|------|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------|
| [7:6] | RSRVD              | RW   | 0x0   | Y      | Reserved.                                                                                                                                  |
| [5:4] | PLLCMOSPREDIV[1:0] | RW   | 0x0   | Y      | PLL LVCMOS Pre-Divider Selection. The PLLCMOSPREDIV field selects the divider value for the PLL pre-divider that drives the CMOS Dividers. |
|       |                    |      |       |        | PLLCMOSPREDIV      Divider Value                                                                                                           |

**10.6.49 PLL\_CTRL0 Register; R56**

The PLL\_CTRL0 register provides control of PLL. The PLL\_CTRL0 register fields are described in the following table.

| Bit # | Field       | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                                                          |

| [0]   | PLL_PDN     | RW   | 0     | Y      | PLL Powerdown. The PLL_PDN bit determines whether PLL is automatically enabled and calibrated after a hardware reset. If the PLL_PDN bit is set to 1 during normal operation then PLL is disabled and the calibration circuit is reset. When PLL_PDN is then cleared to 0 PLL is re-enabled and the calibration sequence is automatically restarted. |

**10.6.50 PLL\_CTRL1 Register; R57**

The PLL\_CTRL1 register provides control of PLL. The PLL\_CTRL1 register fields are described in the following table.

| Bit # | Field       | Type | Reset | EEPROM | Description                                                                                     |
|-------|-------------|------|-------|--------|-------------------------------------------------------------------------------------------------|
| [7:6] | RSRVD       | -    | -     | N      | Reserved.                                                                                       |
| [5]   | RSRVD       | RW   | 0     | Y      | Reserved.                                                                                       |
| [4]   | PRI_D       | RW   | 1     | Y      | Primary Reference Doubler Enable. If PRI_D is 1 the Primary Input Frequency Doubler is enabled. |
| [3:0] | PLL_CP[3:0] | RW   | 0x8   | Y      | PLL Charge Pump Gain. The PLL_CP sets the chargepump current as follows.                        |
|       |             |      |       |        | PLL_CP                                                                                          |
|       |             |      |       |        | Icp (mA)                                                                                        |
|       |             |      |       |        | 1 (0x1)                                                                                         |
|       |             |      |       |        | 0.4                                                                                             |
|       |             |      |       |        | 2 (0x2)                                                                                         |
|       |             |      |       |        | 0.8                                                                                             |
|       |             |      |       |        | 3 (0x3)                                                                                         |

|       |             |      |       |        | 6.4                                                                                             |

### 10.6.51 PLL\_NDIV\_BY1 Register; R58

The 12-bit N integer divider value for PLL is set by the PLL\_NDIV\_BY1 and PLL\_NDIV\_BY0 registers.

| Bit # | Field          | Type | Reset | EEPROM | Description                                               |
|-------|----------------|------|-------|--------|-----------------------------------------------------------|
| [7:4] | RSRVD          | -    | -     | N      | Reserved.                                                 |
| [3:0] | PLL_NDIV[11:8] | RW   | 0x0   | Y      | PLL N Divider Byte 1. PLL Integer N Divider bits 11 to 8. |
|       |                |      |       |        | PLL_NDIV DIVIDER RATIO                                    |
|       |                |      |       |        | 0 (0x000) 1                                               |
|       |                |      |       |        | 1 (0x001) 1                                               |
|       |                |      |       |        | ...                                                       |
|       |                |      |       |        | 4095 (0xFFFF) 4095                                        |

### 10.6.52 PLL\_NDIV\_BY0 Register; R59

The PLL\_NDIV\_BY0 register is described in the following table.

| Bit # | Field         | Type | Reset | EEPROM | Description                                              |
|-------|---------------|------|-------|--------|----------------------------------------------------------|
| [7:0] | PLL_NDIV[7:0] | RW   | 0x66  | Y      | PLL N Divider Byte 0. PLL Integer N Divider bits 7 to 0. |

### 10.6.53 PLL\_FRACNUM\_BY2 Register; R60

The Fractional Divider Numerator value for PLL is set by registers PLL\_FRACNUM\_BY2, PLL\_FRACNUM\_BY1 and PLL\_FRACNUM\_BY0.

| Bit # | Field          | Type | Reset | EEPROM | Description                                             |
|-------|----------------|------|-------|--------|---------------------------------------------------------|
| [7:6] | RSRVD          | -    | -     | N      | Reserved.                                               |
| [5:0] | PLL_NUM[21:16] | RW   | 0x00  | Y      | PLL Fractional Divider Numerator Byte 2. Bits 21 to 16. |

### 10.6.54 PLL\_FRACNUM\_BY1 Register; R61

The PLL\_FRACNUM\_BY1 register is described in the following table.

| Bit # | Field         | Type | Reset | EEPROM | Description                                            |
|-------|---------------|------|-------|--------|--------------------------------------------------------|
| [7:0] | PLL_NUM[15:8] | RW   | 0x00  | Y      | PLL Fractional Divider Numerator Byte 1. Bits 15 to 8. |

### 10.6.55 PLL\_FRACNUM\_BY0 Register; R62

The PLL\_FRACNUM\_BY0 register is described in the following table.

| Bit # | Field        | Type | Reset | EEPROM | Description                                           |
|-------|--------------|------|-------|--------|-------------------------------------------------------|
| [7:0] | PLL_NUM[7:0] | RW   | 0x00  | Y      | PLL Fractional Divider Numerator Byte 0. Bits 7 to 0. |

### 10.6.56 PLL\_FRACDEN\_BY2 Register; R63

The Fractional Divider Denominator value for PLL is set by registers PLL\_FRACDEN\_BY2, PLL\_FRACDEN\_BY1 and PLL\_FRACDEN\_BY0.

| Bit # | Field          | Type | Reset | EEPROM | Description                                               |
|-------|----------------|------|-------|--------|-----------------------------------------------------------|
| [7:6] | RSRVD          | -    | -     | N      | Reserved.                                                 |
| [5:0] | PLL_DEN[21:16] | RW   | 0x00  | Y      | PLL Fractional Divider Denominator Byte 2. Bits 21 to 16. |

**10.6.57 PLL\_FRACDEN\_BY1 Register; R64**

The PLL\_FRACDEN\_BY1 register is described in the following table.

| Bit # | Field         | Type | Reset | EEPROM | Description                                              |
|-------|---------------|------|-------|--------|----------------------------------------------------------|
| [7:0] | PLL_DEN[15:8] | RW   | 0x00  | Y      | PLL Fractional Divider Denominator Byte 1. Bits 15 to 8. |

**10.6.58 PLL\_FRACDEN\_BY0 Register; R65**

The PLL\_FRACDEN\_BY0 register is described in the following table.

| Bit # | Field        | Type | Reset | EEPROM | Description                                             |
|-------|--------------|------|-------|--------|---------------------------------------------------------|
| [7:0] | PLL_DEN[7:0] | RW   | 0x00  | Y      | PLL Fractional Divider Denominator Byte 0. Bits 7 to 0. |

**10.6.59 PLL\_MASHCTRL Register; R66**

The PLL\_MASHCTRL register provides control of the fractional divider for PLL.

| Bit # | Field              | Type | Reset | EEPROM | Description                      |
|-------|--------------------|------|-------|--------|----------------------------------|
| [7:4] | RSRVD              | -    | -     | N      | Reserved.                        |
| [3:2] | PLL_DTH_RMODE[1:0] | RW   | 0x3   | Y      | Mash Engine dither mode control. |
|       |                    |      |       |        | DITHERMODE                       |
|       |                    |      |       |        | 0 (0x0) Weak                     |
|       |                    |      |       |        | 1 (0x1) Medium                   |
|       |                    |      |       |        | 2 (0x2) Strong                   |
|       |                    |      |       |        | 3 (0x3) Dither Disabled          |
| [1:0] | PLL_ORDER[1:0]     | RW   | 0x0   | Y      | Mash Engine Order.               |
|       |                    |      |       |        | ORDER                            |
|       |                    |      |       |        | 0 (0x0) Integer Mode Divider     |
|       |                    |      |       |        | 1 (0x1) 1st order                |
|       |                    |      |       |        | 2 (0x2) 2nd order                |
|       |                    |      |       |        | 3 (0x3) 3rd order                |

**10.6.60 PLL\_LF\_R2 Register; R67**

The PLL\_LF\_R2 register controls the value of the PLL Loop Filter R2.

| Bit # | Field          | Type | Reset | EEPROM | Description                                                                                            |
|-------|----------------|------|-------|--------|--------------------------------------------------------------------------------------------------------|
| [7:6] | RSRVD          | -    | -     | N      | Reserved.                                                                                              |
| [5:0] | PLL_LF_R2[5:0] | RW   | 0x24  | Y      | PLL Loop Filter R2. NOTE: Table below lists commonly used R2 values but more selections are available. |
|       |                |      |       |        | PLL_LF_R2[5:0] R2 ( $\Omega$ )                                                                         |
|       |                |      |       |        | 1 (0x01) 236                                                                                           |
|       |                |      |       |        | 2 (0x02) 336                                                                                           |
|       |                |      |       |        | 4 (0x04) 536                                                                                           |
|       |                |      |       |        | 8 (0x08) 735                                                                                           |
|       |                |      |       |        | 32 (0x20) 1636                                                                                         |
|       |                |      |       |        | 48 (0x30) 2418                                                                                         |

**10.6.61 PLL\_LF\_C1 Register; R68**

The PLL\_LF\_C1 register controls the value of the PLL Loop Filter C1.

| Bit # | Field          | Type | Reset | EEPROM | Description                                                                                |
|-------|----------------|------|-------|--------|--------------------------------------------------------------------------------------------|
| [7:3] | RSRVD          | -    | -     | N      | Reserved.                                                                                  |
| [2:0] | PLL_LF_C1[2:0] | RW   | 0x0   | Y      | PLL Loop Filter C1. The value in pF is given by $5 + 50 * \text{PLL\_LF\_C1}$ (in binary). |

### 10.6.62 PLL\_LF\_R3 Register; R69

The PLL\_LF\_R3 register controls the value of the PLL Loop Filter R3.

| Bit # | Field           | Type | Reset | EEPROM | Description                                                                                            |        |
|-------|-----------------|------|-------|--------|--------------------------------------------------------------------------------------------------------|--------|
| [7]   | RSRVD           | -    | -     | N      | Reserved.                                                                                              |        |
| [6:1] | PLL_LF_R3[5:0]  | RW   | 0x0   | Y      | PLL Loop Filter R3. NOTE: Table below lists commonly used R3 values but more selections are available. |        |
|       |                 |      |       |        | PLL_LF_R3[5:0]                                                                                         | R3 (Ω) |
|       |                 |      |       |        | 0 (0x00)                                                                                               | 18     |
|       |                 |      |       |        | 2 (0x02)                                                                                               | 318    |
|       |                 |      |       |        | 4 (0x04)                                                                                               | 518    |
|       |                 |      |       |        | 8 (0x08)                                                                                               | 717    |
|       |                 |      |       |        | 16 (0x10)                                                                                              | 854    |
|       |                 |      |       |        | 32 (0x20)                                                                                              | 1654   |
|       |                 |      |       |        | 64 (0x40)                                                                                              | 3254   |
| [0]   | PLL_LF_INT_FRAC | RW   | 0     | Y      | PLL Loop Filter Setting. Set to 0 for integer PLL and to 1 for fractional PLL.                         |        |

### 10.6.63 PLL\_LF\_C3 Register; R70

The PLL\_LF\_C3 register controls the value of the PLL Loop Filter C3.

| Bit # | Field          | Type | Reset | EEPROM | Description                                                                           |
|-------|----------------|------|-------|--------|---------------------------------------------------------------------------------------|
| [7:3] | RSRVD          | -    | -     | N      | Reserved.                                                                             |
| [2:0] | PLL_LF_C3[2:0] | RW   | 0x0   | Y      | PLL Loop Filter C3. The value in pF is given by $5 * \text{PLL\_LF\_C3}$ (in binary). |

### 10.6.64 SEC\_CTRL Register; R72

The SEC\_CTRL register controls the value of the Secondary Reference Doubler.

| Bit # | Field | Type | Reset | EEPROM | Description                                                                                         |
|-------|-------|------|-------|--------|-----------------------------------------------------------------------------------------------------|
| [7:6] | RSRVD | -    | -     | N      | Reserved.                                                                                           |
| [5]   | RSRVD | RW   | 0     | Y      | Reserved.                                                                                           |
| [4]   | SEC_D | RW   | 1     | Y      | Secondary Reference Doubler Enable. If SEC_D is 1 the Secondary Input Frequency Doubler is enabled. |
| [3:0] | RSRVD | RW   | 0x8   | Y      | Reserved.                                                                                           |

JAJ5FA5E – SEPTEMBER 2015 – REVISED APRIL 2018

[www.ti.com](http://www.ti.com)
**10.6.65 XO\_MARGINING Register; R86**

Margin Control

| Bit # | Field                | Type | Reset | EEPROM | Description                                                                                                                                                                                          |
|-------|----------------------|------|-------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7]   | RSRVD                | -    | -     | N      | Reserved.                                                                                                                                                                                            |
| [6:4] | MARGIN_DIG_STEP[2:0] | R    | 0x0   | N      | Margin Digital Step. MARGIN_DIG_STEP allows the current level of the margin selection pin (GPIO[5]) to be read.                                                                                      |
|       |                      |      |       |        | MARGIN_DIG_STEP                                                                                                                                                                                      |
|       |                      |      |       |        | Value                                                                                                                                                                                                |
|       |                      |      |       |        | 0 (0x0)                                                                                                                                                                                              |
|       |                      |      |       |        | STEP1                                                                                                                                                                                                |
|       |                      |      |       |        | 1 (0x1)                                                                                                                                                                                              |

### 10.6.86 PLL\_CALCTRL0 Register; R119

The PLL\_CALCTRL0 register is described in the following table.

| Bit #   | Field                  | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                      |                                           |
|---------|------------------------|------|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| [7:4]   | RSRVD                  | -    | -     | N      | Reserved.                                                                                                                                                                                                                                        |                                           |
| [3:2]   | PLL_CLSDW<br>AIT[1:0]  | RW   | 0x0   | Y      | Closed Loop Wait Period. The CLSDWAIT field sets the closed loop wait period, in periods of the always on clock as follows. Use 0x1 for clock generator mode (> 10 kHz loop bandwidth) and 0x3 for jitter cleaner mode (< 1 kHz loop bandwidth). |                                           |
|         |                        |      |       |        | CLSDWAIT                                                                                                                                                                                                                                         | Analog closed loop VCO stabilization time |
|         |                        |      |       |        | 0 (0x0)                                                                                                                                                                                                                                          | 30 μs                                     |

JAJ5FA5E –SEPTEMBER 2015–REVISED APRIL 2018

[www.ti.com](http://www.ti.com)
**10.6.87 PLL\_CALCTRL1 Register; R120**

The PLL\_CALCTRL1 register is described in the following table.

| Bit # | Field      | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                                                    |
|-------|------------|------|-------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:1] | RSRVD      | -    | -     | N      | Reserved.                                                                                                                                                                                                                                                                                                                                      |
| [0]   | PLL_LOOPBW | RW   | 0     | Y      | PLL Loop bandwidth Control. When PLL_LOOPBW is 1 the loop bandwidth of PLL is reduced to 200 Hz (jitter cleaner mode). When PLL_LOOPBW is 0 the loop bandwidth of PLL is set to its normal range (clock generator mode). NOTE: Proper PLL settings must be used (PFD, charge pump, loop filter) with setting the desired value for PLL_LOOPBW. |

**10.6.88 NVMCNT Register; R136**

The NVMCNT register is intended to reflect the number of on-chip EEPROM Erase/Program cycles that have taken place in EEPROM. The count is automatically incremented by hardware and stored in EEPROM.

| Bit # | Field       | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                                                                |
|-------|-------------|------|-------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | NVMCNT[7:0] | R    | 0x00  | Y      | EEPROM Program Count. The NVMCNT increments automatically after every EEPROM Erase/Program Cycle. The NVMCNT value is retrieved automatically after reset, after a EEPROM Commit operation or after a Erase/Program cycle. The NVMCNT register will increment until it reaches its maximum value of 255 after which no further increments will take place. |

**10.6.89 NVMCTL Register; R137**

The NVMCTL register allows control of the on-chip EEPROM Memories.

| Bit # | Field      | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|------------|------|-------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7]   | RSRVD      | -    | -     | N      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| [6]   | REGCOMMIT  | RWSC | 0     | N      | REG Commit to EEPROM SRAM Array. The REGCOMMIT bit is used to initiate a transfer from the on-chip registers back to the corresponding location in the EEPROM SRAM Array. The REGCOMMIT bit is automatically cleared to 0 when the transfer is complete. The particular page of SRAM used as the destination for the transfer is selected by the REGCOMMIT_PAGE register.                                                                                                                                                                |
| [5]   | NVMCRCE    | R    | 0     | N      | EEPROM CRC Error Indication. The NVMCRCE bit is set to 1 if a CRC Error has been detected when reading back from on-chip EEPROM during device configuration.                                                                                                                                                                                                                                                                                                                                                                             |
| [4]   | NVMAUTOCRC | RW   | 1     | N      | EEPROM Automatic CRC. When NVMAUTOCRC is 1 then the EEPROM Stored CRC byte is automatically calculated whenever an EEPROM program takes place.                                                                                                                                                                                                                                                                                                                                                                                           |
| [3]   | NVMCOMMIT  | RWSC | 0     | N      | EEPROM Commit to Registers. The NVMCOMMIT bit is used to initiate a transfer of the on-chip EEPROM contents to internal registers. The transfer happens automatically after reset or when NVMCOMMIT is set to 1. The NVMCOMMIT bit is automatically cleared to 0. The I <sup>2</sup> C registers cannot be read while a EEPROM Commit operation is taking place. The NVMCOMMIT operation can only be carried out when the Always On Clock is active. The Always On Clock can be kept running after lock by setting the AONAFTERLOCK bit. |
| [2]   | NVMBUSY    | R    | 0     | N      | EEPROM Program Busy Indication. The NVMBUSY bit is 1 during an on-chip EEPROM Erase/Program cycle. While NVMBUSY is 1 the on-chip EEPROM cannot be accessed.                                                                                                                                                                                                                                                                                                                                                                             |
| [1]   | RSRVD      | RWSC | 0     | N      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| [0]   | NVMPROG    | RWSC | 0     | N      | EEPROM Program Start. The NVMPROG bit is used to begin an on-chip EEPROM Erase/Program cycle. The Erase/Program cycle is only initiated if the immediately preceding I <sup>2</sup> C transaction was a write to the NVMUNLK register with the appropriate code. The NVMPROG bit is automatically cleared to 0. The EEPROM Erase/Program operation takes around 230 ms.                                                                                                                                                                  |

**10.6.90 NVMLCRC Register; R138**

The NVMLCRC register holds the Live CRC byte that has been calculated while reading on-chip EEPROM.

| Bit # | Field        | Type | Reset | EEPROM | Description      |
|-------|--------------|------|-------|--------|------------------|
| [7:0] | NVMLCRC[7:0] | R    | 0x00  | N      | EEPROM Live CRC. |

### 10.6.91 MEMADR\_BY1 Register; R139

The MEMADR\_BY1 register holds the MSB of the starting address for on-chip SRAM or EEPROM access.

| Bit # | Field               | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                        |
|-------|---------------------|------|-------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:4] | RSRVD               | -    | -     | N      | Reserved.                                                                                                                                                                                                                                                                          |
| [3:0] | MEMADR[11:8]        | RW   | 0x0   | N      | Memory Address. The MEMADR value determines the starting address for access to the on-chip memories. The on-chip memories and the corresponding address ranges are listed below. The data from the selected address is then accessed using one of the data registers listed below. |
|       | MEMORY              |      |       |        | MEMADR Range Data Register                                                                                                                                                                                                                                                         |
|       | EEPROM EEPROM-Array |      |       |        | MEMADR[8:0] NVMDAT                                                                                                                                                                                                                                                                 |
|       | EEPROM SRAM-Array   |      |       |        | MEMADR[8:0] RAMDAT                                                                                                                                                                                                                                                                 |
|       | ROM-Array           |      |       |        | MEMADR[11:0] ROMDAT                                                                                                                                                                                                                                                                |

### 10.6.92 MEMADR\_BY0 Register; R140

The MEMADR\_BY0 register holds the lower 8-bits of the starting address for on-chip SRAM or EEPROM access.

| Bit # | Field       | Type | Reset | EEPROM | Description     |
|-------|-------------|------|-------|--------|-----------------|
| [7:0] | MEMADR[7:0] | RW   | 0x00  | N      | Memory Address. |

### 10.6.93 NVMDAT Register; R141

The NVMDAT register returns the on-chip EEPROM contents from the starting address specified by the MEMADR register.

| Bit # | Field       | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|-------------|------|-------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | NVMDAT[7:0] | R    | 0x00  | N      | EEPROM Read Data. The first time an I <sup>2</sup> C read transaction accesses the NVMDAT register address, either because it was explicitly targeted or because the address was auto-incremented, the read transaction will return the EEPROM data located at the address specified by the MEMADR register. Any additional read's which are part of the same transaction will cause the EEPROM address to be incremented and the next EEPROM data byte will be returned. The I <sup>2</sup> C address will no longer be auto-incremented, that is, the I <sup>2</sup> C address will be locked to the NVMDAT register after the first access. Access to the NVMDAT register will terminate at the end of the current I <sup>2</sup> C transaction. |

### 10.6.94 RAMDAT Register; R142

The RAMDAT register provides read and write access to the SRAM that forms part of the on-chip EEPROM module.

| Bit # | Field       | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|-------------|------|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | RAMDAT[7:0] | RW   | 0x00  | N      | RAM Read/Write Data. The first time an I <sup>2</sup> C read or write transaction accesses the RAMDAT register address, either because it was explicitly targeted or because the address was auto-incremented, a read transaction will return the RAM data located at the address specified by the MEMADR register and a write transaction will cause the current I <sup>2</sup> C data to be written to the address specified by the MEMADR register. Any additional accesses which are part of the same transaction will cause the RAM address to be incremented and a read or write access will take place to the next SRAM address. The I <sup>2</sup> C address will no longer be auto-incremented, that is, the I <sup>2</sup> C address will be locked to the RAMDAT register after the first access. Access to the RAMDAT register will terminate at the end of the current I <sup>2</sup> Cs transaction. |

### 10.6.95 ROMDAT Register; R143

The romdat register provides read to the on-chip ROM module.

| Bit # | Field       | Type | Reset | EEPROM | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|-------------|------|-------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | ROMDAT[7:0] | R    | 0x00  | N      | ROM Read Data. The first time an I <sup>2</sup> C read or write transaction accesses the romdat register address, either because it was explicitly targeted or because the address was auto-incremented, a read transaction will return the ROM data located at the address specified by the MEMADR register. Any additional accesses which are part of the same transaction will cause the ROM address to be incremented and a read access will take place to the next ROM address. The I <sup>2</sup> C address will no longer be auto-incremented, that is, the I <sup>2</sup> C address will be locked to the romdat register after the first access. Access to the ROMDAT register will terminate at the end of the current I <sup>2</sup> C transaction. |

### 10.6.96 NVMUNLK Register; R144

The NVMUNLK register provides a rudimentary level of protection to prevent inadvertent programming of the on-chip EEPROM.

| Bit # | Field        | Type | Reset | EEPROM | Description                                                                                                                                                                                                                      |
|-------|--------------|------|-------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:0] | NVMUNLK[7:0] | RW   | 0x0   | N      | EEPROM Prog Unlock. The NVMUNLK register must be written immediately prior to setting the NVMPROG bit of register NVMCTL, otherwise the Erase/Program cycle will not be triggered. NVMUNLK must be written with a value of 0xEA. |

### 10.6.97 REGCOMMIT\_PAGE Register; R145

The REGCOMMIT\_PAGE register determines the region of the EEPROM/SRAM array that is populated by the REGCOMMIT operation.

| Bit # | Field             | Type | Reset | EEPROM | Description                                                                                                                                                                      |
|-------|-------------------|------|-------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [7:4] | RSRVD             | -    | -     | N      | Reserved.                                                                                                                                                                        |
| [3:0] | REGCOMMIT_PG[3:0] | RW   | 0x0   | N      | Register Commit Page (1 of 6 available pages that can be selected by the GPIO[3:2] pins for default powerup state. NOTE: Valid page values are 0 to 5. Do not use other values.) |

### 10.6.98 XOCAPCTRL\_BY1 Register; R199

The XOCAPCTRL\_BY1 and XOCAPCTRL\_BY0 registers allow read-back of the XOCAPCTRL value that displays the on-chip load capacitance selected for the crystal.

| Bit # | Field            | Type | Reset | EEPROM | Description           |
|-------|------------------|------|-------|--------|-----------------------|
| [7:2] | RSRVD            | -    | -     | N      | Reserved.             |
| [1:0] | XO_CAP_CTRL[9:8] | R    | 0x0   | N      | XO CAP CTRL register. |

### 10.6.99 XOCAPCTRL\_BY0 Register; R200

The XOCAPCTRL\_BY1 and XOCAPCTRL\_BY0 registers allow read-back of the XOCAPCTRL value that displays the on-chip load capacitance selected for the crystal.

| Bit # | Field            | Type | Reset | EEPROM | Description           |
|-------|------------------|------|-------|--------|-----------------------|
| [7:0] | XO_CAP_CTRL[7:0] | R    | 0x00  | N      | XO CAP CTRL register. |

### 10.6.100 EEPROM Map

The EEPROM map is shown in the table below. There are 6 EEPROM pages and the common EEPROM bits are shown first. Any bit that is labeled as "RSRVD" should be written with a 0.

| Byte # | Bit7                    | Bit6                 | Bit5                 | Bit4                 | Bit3                 | Bit2                | Bit1                | Bit0                    |
|--------|-------------------------|----------------------|----------------------|----------------------|----------------------|---------------------|---------------------|-------------------------|
| 0      | RSRVD                   | RSRVD                | RSRVD                | RSRVD                | RSRVD                | RSRVD               | RSRVD               | 1                       |
| 1      | RSRVD                   | RSRVD                | RSRVD                | RSRVD                | RSRVD                | RSRVD               | RSRVD               | RSRVD                   |
| 2      | RSRVD                   | RSRVD                | RSRVD                | RSRVD                | RSRVD                | RSRVD               | RSRVD               | RSRVD                   |
| 3      | RSRVD                   | RSRVD                | RSRVD                | RSRVD                | RSRVD                | RSRVD               | RSRVD               | RSRVD                   |

## 11 Application and Implementation

### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 11.1 Application Information

The LMK03318 is an ultra-low jitter clock generator that can be used to provide reference clocks for high-speed serial links resulting in improved system performance. The LMK03318 also supports a variety of features that aids the hardware designer during the system debug and validation phase.

### 11.2 Typical Applications

#### 11.2.1 Application Block Diagram Examples

### 11.2.2 Jitter Considerations in Serdes Systems

Jitter-sensitive applications such as 10 Gbps or 100 Gbps Ethernet, deploy a serial link utilizing a serializer in the transmit section (TX) and a De-serializer in the receive section (RX). These SERDES blocks are typically embedded in an ASIC or FPGA. Estimating the clock jitter impact on the link budget requires understanding of the TX PLL bandwidth and the RX CDR bandwidth.

As can be seen in [Figure 80](#), the pass band region between the TX low pass cutoff and RX high pass cutoff frequencies is the range over which the reference clock jitter adds without any attenuation to the jitter budget of the link. Outside of these frequencies, the SERDES link will attenuate the reference clock jitter with a 20 dB/dec or even steeper roll-off. Modern ASIC or FPGA designs have some flexibility on deciding the optimal RX CDR bandwidth and TX PLL bandwidth. These bandwidths are typically set based on what is achievable in the ASIC or FPGA process node, without increasing design complexity, and on any jitter tolerance or wander specification that must be met, as related to the RX CDR bandwidth.

The overall allowable jitter in a serial link is dictated by IEEE or other relevant standards. For example, IEEE802.3ba states that the maximum transmit jitter (peak-peak) for 10 Gbps Ethernet should be no more than  $0.28 * UI$  and this equates to a 27.1516 ps, p-p for the overall allowable transmit jitter.

The jitter contributing elements are made up of the reference clock, generated potentially from a device like LMK03318, the transmit medium, transmit driver etc. Only a portion of the overall allowable transmit jitter is allocated to the reference clock, typically 20% or lower. Therefore, the allowable reference clock jitter, for a 20% clock jitter budget, is 5.43 ps, p-p.

Jitter in a reference clock is made up of deterministic jitter (arising from spurious signals due to supply noise or mixing from other outputs or from the reference input) and random jitter (usually due to thermal noise and other uncorrelated noise sources). A typical clock tree in a serial link system consists of clock generators and fanout buffers. The allowable reference clock jitter of 5.43 ps, p-p is needed at the output of the fanout buffer. Modern fanout buffers have low additive random jitter (less than 100 fs, rms) with no substantial contribution to the deterministic jitter. Therefore, the clock generator and fanout buffer contribute to the random jitter while the primary contributor to the deterministic jitter is the clock generator. Rule of thumb, for modern clock generators, is to allocate 25% of allowable reference clock jitter to the deterministic jitter and 75% to the random jitter. This

## Typical Applications (continued)

amounts to an allowable deterministic jitter of 1.36 ps, p-p and an allowable random jitter of 4.07 ps, p-p. For serial link systems that need to meet a BER of  $10^{-12}$ , the allowable random jitter in root-mean-square is 0.29 ps, rms. This is calculated by dividing the p-p jitter by 14 for a BER of  $10^{-12}$ . Accounting for random jitter from the fanout buffer, the random jitter needed from the clock generator is 0.27 ps, rms. This is calculated by the root-mean-square subtraction from the desired jitter at the fanout buffer's output assuming 100 fs, rms of additive jitter from the fanout buffer.

With careful frequency planning techniques, like spur optimization (covered in the [Spur Mitigation Techniques](#) section) and on-chip LDOs to suppress supply noise, the LMK03318 is able to generate clock outputs with deterministic jitter that is below 1 ps, p-p and random jitter that is below 0.2 ps, rms. This gives the serial link system with additional margin on the allowable transmit jitter resulting in a BER better than  $10^{-12}$ .

## Typical Applications (continued)

Figure 80. Dependence of Clock Jitter in Serial Links

## Typical Applications (continued)

### 11.2.3 Frequency Margining

#### 11.2.3.1 Fine Frequency Margining

IEEE802.3 dictates that Ethernet frames stay compliant to the standard specifications when clocked with a reference clock that is within  $\pm 100$  ppm of its nominal frequency. In the worst case, an RX node with its local reference clock at  $-100$  ppm from its nominal frequency should be able to work seamlessly with a TX node that has its own local reference clock at  $+100$  ppm from its nominal frequency. Without any clock compensation on the RX node, the read pointer will severely lag behind the write pointer and cause FIFO overflow errors. On the contrary, when the RX node's local clock operates at  $100$  ppm from its nominal frequency and the TX node's local clock operates at  $-100$  ppm from its nominal frequency, FIFO underflow errors occur without any clock compensation.

To prevent such overflow and underflow errors from occurring, modern ASICs and FGPAs include a clock compensation scheme that introduces elastic buffers. Such a system, shown in Figure 80, is validated thoroughly during the validation phase by interfacing slower nodes with faster ones and ensuring compliance to IEEE802.3. The LMK03318 provides the ability to fine tune the frequency of its outputs based on changing its on-chip load capacitance when operated with a crystal input. This fine tuning can be done through I2C or through the GPIO5 pin as described in [Crystal Input Interface \(SEC\\_REF\)](#). A total of  $\pm 50$  ppm frequency tuning is achievable when using pullable crystals whose C0/C1 ratio is less than 250. The change in load capacitance is implemented in a manner such that the outputs of the LMK03318 undergo a smooth monotonic change in frequency.

Figure 81. System Implementation with Clock Compensation for Standards Compliance

#### 11.2.3.2 Coarse Frequency Margining

Certain systems require the processors to be tested at clock frequencies that are slower or faster by 5% or 10%. The LMK03318 offers the ability to change its output dividers for the desired change from its nominal output frequency without resulting in any glitches (as explained in [High-Speed Output Divider](#)).

## Typical Applications (continued)

### 11.2.4 Design Requirements

Consider a typical wired communications application, like a top-of-rack switch, which needs to clock high data rate 10 Gbps or 100 Gbps Ethernet PHYs and other macros like PCI Express, Fast Ethernet and CPLD. For such asynchronous systems, the reference input can be a crystal. In such systems, the clocks are expected to be available upon powerup without the need for any device-level programming. An example of the clock input and output requirements is :

- Clock Input:
  - 25-MHz crystal
- Clock Outputs:
  - 2x 156.25-MHz clock for uplink 10.3125 Gbps, LVPECL
  - 2x 125-MHz clock for downlink 3.125 Gbps, LVPECL
  - 2x 100-MHz clock for PCI Express, HCSL
  - 1x 25-MHz clock for Fast Ethernet, LVDS
  - 2x 33.3333-MHz clock for CPLD, 1.8-V LVCMOS

The section below describes the detailed design procedure to generate the required output frequencies for the above scenario using LMK03318.

#### 11.2.4.1 Detailed Design Procedure

Design of all aspects of the LMK03318 is quite involved, and software support is available to assist in part selection, part programming, loop filter design, and phase-noise simulation. This design procedure will give a quick outline of the process.

1. Device Selection
  - The first step to calculate the specified VCO frequency given required output frequencies. The device must be able to produce the VCO frequency that can be divided down to the required output frequencies.
  - The WEBENCH Clock Architect Tool from TI will aid in the selection of the right device that meets the customer's output frequencies and format requirements.
2. Device Configuration
  - There are many device configurations to achieve the desired output frequencies from a device. However there are some optimizations and trade-offs to be considered.
  - The WEBENCH Clock Architect Tool attempts to maximize the phase detector frequency, use smallest dividers, and maximizes PLL charge pump current.
  - These guidelines below may be followed when configuring PLL related dividers or other related registers:
    - For lowest possible in-band PLL flat noise, maximize phase detector frequency to minimize N divide value.
    - For lowest possible in-band PLL flat noise, maximize charge pump current. The highest value charge pump currents often have similar performance due to diminishing returns.
    - To reduce loop filter component sizes, increase N value and/or reduce charge pump current.
    - For fractional divider values, keep the denominator at highest value possible to minimize spurs. It is also best to use higher order modulator wherever possible for the same reason.
    - As a rule of thumb, keeping the phase detector frequency approximately between  $10 \times \text{PLL loop bandwidth}$  and  $100 \times \text{PLL loop bandwidth}$ . A phase detector frequency less than  $5 \times \text{PLL bandwidth}$  may be unstable and a phase detector frequency  $> 100 \times \text{loop bandwidth}$  may experience increased lock time due to cycle slipping.
3. PLL Loop Filter Design
  - TI recommends using the WEBENCH Clock Architect Tool to design your loop filter.
  - Optimal loop filter design and simulation can be achieved when custom reference phase noise profiles are loaded into the software tool.
  - While designing the loop filter, adjusting the charge pump current or N value can help with loop filter component selection. Lower charge pump currents and larger N values result in smaller component values but may increase impacts of leakage and reduce PLL phase noise performance.
  - For a more detailed understanding of loop filter design can be found in Dean Banerjee's *PLL*

## Typical Applications (continued)

*Performance, Simulation, and Design* ([www.ti.com/tool/pll\\_book](http://www.ti.com/tool/pll_book)).

### 4. Clock Output Assignment

- At the time of writing this datasheet, the design software does not take into account frequency assignment to specific outputs except to ensure that the output frequencies can be achieved. It is best to consider proximity of the clock outputs to each other and other PLL circuitry when choosing final clock output locations. Here are some guidelines to help achieve optimal performance when assigning outputs to specific clock output pins.
  - Group common frequencies together.
  - PLL charge pump circuitry can cause crosstalk at the charge pump frequency. Place outputs sharing charge pump frequency or lower priority outputs not sensitive to charge pump frequency spurs together.
  - Clock output MUXes can create a path for noise coupling. Factor in frequencies which may have some bleedthrough from non-selected mux inputs.
  - If possible, use outputs 0, 1, 2 or 3 since they don't have MUX in the clock path and have limited opportunity for cross coupled noise.

### 5. Device Programming

- The EVM programming software tool CodeLoader can be used to program the device with the desired configuration.

#### 11.2.4.1.1 Device Selection

Use the WEBENCH Clock Architect Tool. Enter the required frequencies and formats into the tool. To use this device, find a solution using the LMK03318.

##### 11.2.4.1.1.1 Calculation Using LCM

In this example, the LCM (156.25 MHz, 125 MHz, 100 MHz, 33.3333 MHz, 25 MHz) = 2500 MHz. Valid VCO frequency for LMK03318 is 5 GHz (2500 × 2).

##### 11.2.4.1.2 Device Configuration

For this example, when using the WEBENCH Clock Architect Tool, the reference would have been manually entered as 25 MHz according to input frequency requirements. Enter the desired output frequencies and click on 'Generate Solutions'. Select LMK03318 from the solution list.

From the simulation page of the WEBENCH Clock Architect Tool, it can be seen that to maximize phase detector frequencies, the PLL's R and M dividers are set to 1, doublers are disabled and N divider is set to 200. This results in a VCO frequency of 5 GHz. The tool also tries to select maximum possible value for the PLL post divider and for this example, it is set to 2. At this point the design meets all input and output frequency requirements and it is possible to design a loop filter for system and simulate performance on the clock outputs. However, consider also the following:

- At the time of release of this datasheet, the WEBENCH Clock Architect Tool doesn't assign outputs strategically for minimizing cross-coupled spurs and jitter.

##### 11.2.4.1.3 PLL Loop Filter Design

The WEBENCH Clock Architect Tool allows loading a custom phase noise plot for reference inputs. For improved accuracy in simulation and optimum loop filter design, be sure to load these custom noise profiles. After loading a phase noise plot, user should recalculate the recommended loop filter design. The WEBENCH Clock Architect Tool will return solutions with high reference or phase detector frequencies by default. In the WEBENCH Clock Architect Tool the user may increase the reference divider to reduce the frequency if desired.

The next section will discuss PLL loop filter design specific to this example using default phase noise profiles.

## Typical Applications (continued)

### NOTE

The WEBENCH Clock Architect Tool provides optimal loop filters upon selecting a solution from the solution list to simulate for the first time. Anytime PLL related inputs change, like input phase noise, charge pump current, divider values, and so forth, it is best to use the tool to re-calculate the optimal loop filter component values.

#### 11.2.4.1.3.1 PLL Loop Filter Design

In the WEBENCH Clock Architect Tool simulator, click on the PLL loop filter design button, then press recommend design. For the PLL loop filter, maximum phase detector frequency and maximum charge pump current are typically used. The tool recommends a loop filter that is designed to minimize jitter. The integrated loop filters' components are minimized with this recommendation as to allow maximum flexibility in achieving wide loop bandwidths for low PLL noise. With the recommended loop filter calculated, this loop filter is ready to be simulated.

The PLL loop filter's bode plot can additionally be viewed and adjustments can be made to the integrated components. The effective loop bandwidth and phase margin with the updated values is then calculated. The integrated loop filter components are good to use when attempting to eliminate certain spurs. The recommended procedure is to increase C3 capacitance, then R3 resistance. Large R3 resistance can result in degraded VCO phase noise performance.

#### 11.2.4.1.4 Clock Output Assignment

At this time the WEBENCH Clock Architect Tool does not assign output frequencies to specific output ports on the device with the intention to minimize cross-coupled spurs and jitter. The user may wish to make some educated re-assignment of outputs when using the EVM programming tool to configure the device registers appropriately.

In an effort to optimize device configuration for best jitter performance, consider the following guidelines:

- Because the clock outputs, intended to be used to clock high data rates, are needed with lowest possible jitter, it is best to assign 156.25 MHz to outputs 0, 1 and assign 125 MHz to outputs 2, 3.
- Coupling between outputs at different frequencies appear as spurs at offsets that is at the frequency difference between the outputs and its harmonics. Typical SerDes reference clocks need to have low integrated jitter upto an offset of 20 MHz and thus, to minimize cross coupling between output 3 and output 4, it is best to assign 100 MHz to outputs 4 and 5.
- The 25 MHz can then be assigned to output 6.
- The 1.8-V LVCMOS clock at 33.3333 MHz is assigned to output 7 and it is best to select complementary LVCMOS operation. This helps to minimize coupling from this output channel to other outputs.

#### 11.2.4.2 Spur Mitigation Techniques

The LMK03318 offers several programmable features for optimizing fractional spurs. To get the best out of these features, it makes sense to understand the different kinds of spurs as well as their behaviors, causes, and remedies. Although optimizing spurs may involve some trial and error, there are ways to make this process more systematic.

##### 11.2.4.2.1 Phase Detector Spurs

The phase detector spur occurs at an offset from the carrier equal to the phase detector frequency,  $f_{PD}$ . To minimize this spur, a lower phase detector frequency should be considered. In some cases where the loop bandwidth is very wide relative to the phase detector frequency, some benefit might be gained from using a narrower loop bandwidth or adding poles to the loop filter by using R3 and C3 if previously unused, but otherwise the loop filter has minimal impact. Bypassing at the supply pins and board layout can also have an impact on this spur, especially at higher phase detector frequencies.

## Typical Applications (continued)

### 11.2.4.2.2 Integer Boundary Fractional Spurs

This spur occurs at an offset equal to the difference between the VCO frequency and the closest integer channel for the VCO. For instance, if the phase detector frequency is 100 MHz and the VCO frequency is 5003 MHz, then the integer boundary spur would be at 3 MHz offset. This spur can be either PLL or VCO dominated. If it is PLL dominated, decreasing the loop bandwidth and some of the programmable fractional words may impact this spur. If the spur is VCO dominated, then reducing the loop filter will not help, but rather reducing the phase detector and having good slew rate and signal integrity at the selected reference input will help.

### 11.2.4.2.3 Primary Fractional Spurs

These spurs occur at multiples of  $f_{PD}/DEN$  and are not integer boundary spurs. For instance, if the phase detector frequency is 100 MHz and the fraction is 3/100, the primary fractional spurs would be at 1 MHz, 2 MHz, 4 MHz, 5 MHz, 6 MHz etc. These are impacted by the loop filter bandwidth and modulator order. If a small frequency error is acceptable, then a larger equivalent fraction may improve these spurs. This larger unequivalent fraction pushes the fractional spur energy to much lower frequencies where they do not significantly impact the system performance.

### 11.2.4.2.4 Sub-Fractional Spurs

These spurs appear at a fraction of  $f_{PD}/DEN$  and depend on modulator order. With the first order modulator, there are no sub-fractional spurs. The second order modulator can produce 1/2 sub-fractional spurs if the denominator is even. A third order modulator can produce sub-fractional spurs at 1/2, 1/3, or 1/6 of the offset, depending if it is divisible by 2 or 3. For instance, if the phase detector frequency is 100 MHz and the fraction is 3/100, no sub-fractional spurs for a first order modulator or sub-fractional spurs at multiples of 1.5 MHz for a second or third order modulator would be expected. Aside from strategically choosing the fractional denominator and using a lower order modulator, another tactic to eliminate these spurs is to use dithering and express the fraction in larger equivalent terms. Since dithering also adds phase noise, its level must be managed to achieve acceptable phase noise and spurious performance.

Table 19 gives a summary of the spurs discussed so far and techniques to mitigate them.

**Table 19. Spurs and Mitigation Techniques**

| SPUR TYPE          | OFFSET                 | WAYS TO REDUCE                                                                                                                                                                                                                                    | TRADE-OFFS                                                                                                                    |
|--------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Phase Detector     | $f_{PD}$               | Reduce Phase Detector Frequency.                                                                                                                                                                                                                  | Although reducing the phase detector frequency does improve this spur, it also degrades phase noise.                          |
| Integer Boundary   | $f_{VCO} \bmod f_{PD}$ | <b>Methods for PLL Dominated Spurs</b><br>-Avoid the worst case VCO frequencies if possible.<br>-Ensure good slew rate and signal integrity at reference input.<br>-Reduce loop bandwidth or add more filter poles to suppress out of band spurs. | Reducing the loop bandwidth may degrade the total integrated noise if the bandwidth is too narrow.                            |
|                    |                        | <b>Methods for VCO Dominated Spurs</b><br>-Avoid the worst case VCO frequencies if possible.<br>-Reduce Phase Detector Frequency.<br>-Ensure good slew rate and signal integrity at reference input.                                              | Reducing the phase detector may degrade the phase noise.                                                                      |
| Primary Fractional | $f_{PD}/DEN$           | -Decrease Loop Bandwidth.<br>-Change Modulator Order.<br>use Larger Unequivalent Fractions.                                                                                                                                                       | Decreasing the loop bandwidth may degrade in-band phase noise. Also, larger unequivalent fractions don't always reduce spurs. |

**Typical Applications (continued)**
**Table 19. Spurs and Mitigation Techniques (continued)**

| SPUR TYPE      | OFFSET                     | WAYS TO REDUCE                                                                                                                                                       | TRADE-OFFS                                               |

## 12 Power Supply Recommendations

### 12.1 Device Power Up Sequence

Figure 82 shows the power up sequence of the LMK03318 in both the hard pin mode and soft pin mode.

Figure 82. Flow Chart for Device Power Up and Configuration

## 12.2 Device Power Up Timing

Before the outputs are enabled after power up, the LMK03318 goes through the initialization routine given in [Table 20](#).

**Table 20. LMK03318 Power Up Initialization Routine**

| Parameter      | Definition                                     | Duration                                                                                             | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|------------------------------------------------|------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $T_{PWR}$      | Step 1: Power up ramp                          | Depends on customer supply ramp time                                                                 | The POR monitor holds the device in power-down/reset until the core supply voltages reaches 2.72 V (min) to 2.95 V (max) and VDDO_01 reaches 1.7 V (min).                                                                                                                                                                                                                                                                                                                    |
| $T_{XO}$       | Step 2: XO startup (if crystal is used)        | Depends on XTAL. Could be several ms; For TXC 25 MHz typical XTAL startup time measures 100 $\mu$ s. | This step assumes PDN=1. The XTAL startup time is the time it takes for the XTAL to oscillate with sufficient amplitude. The LMK03318 has a built-in amplitude detection circuit, and halts the PLL lock sequence until the XTAL stage has sufficient swing.                                                                                                                                                                                                                 |
| $T_{CAL-PLL}$  | Step 3: Closed loop calibration period for PLL | Programmable cycles of internal 10 MHz oscillator.                                                   | This counter is needed for the PLL loop to stabilize. It can also be used to provide additional delay time for the selected PLL reference input to stabilize, in case the reference detection circuit validates the input too soon. The duration can range from 30 $\mu$ s to 300 ms and programmed in R119[3-2]. Recommended duration for PLL as clock generator (loop bandwidth > 10 kHz) is 300 $\mu$ s and for PLL as jitter cleaner (loop bandwidth < 1 kHz) is 300 ms. |
| $T_{VCO}$      | Step 4: VCO wait period                        | Programmable cycles of internal 10 MHz oscillator.                                                   | This counter is needed for the VCO to stabilize. The duration can range from 20 $\mu$ s to 200 ms and programmed in R119[1-0]. Recommended duration for VCO1 is 400 $\mu$ s.                                                                                                                                                                                                                                                                                                 |
| $T_{LOCK-PLL}$ | Step 5: PLL lock time                          | $\sim 4/LBW$ of PLL                                                                                  | The Outputs turn on immediately after calibration. A small frequency error remains for the duration of $\sim 4/LBW$ (so in clock generator mode typically 10 $\mu$ s for a PLL bandwidth of 400 kHz). The initial output frequency will be lower than the target output frequency, as the loop filter starts out initially discharged.                                                                                                                                       |
| $T_{LOL-PLL}$  | Step 6: PLL LOL indicator low                  | $\sim 1$ PFD clock cycle                                                                             | The PLL loss of lock indicator if selected on STATUS0 or STATUS1 will go low after 1 PFD clock cycle to indicate PLL is now locked.                                                                                                                                                                                                                                                                                                                                          |

The LMK03318 start-up time for the PLL is defined as the time taken, from the moment the core supplies reach 2.72 V and VDDO\_01 reaches 1.7 V, for the PLL to be locked and valid outputs are available at the outputs with no more than  $\pm 300$  ppm error. Start-up time for the PLL can be calculated as [Equation 5](#)

$$T_{\text{PLL-SU}} = T_{\text{XO}} + T_{\text{CAL-PLL}} + T_{\text{VCO}} + T_{\text{LOCK-PLL}} \quad (5)$$

### 12.3 Power Down

The PDN pin (active low) can be used both as device power-down pin and to initialize the device. When this pin is pulled low, the entire device is powered down. When it is pulled high, the power-on reset (POR) sequence is triggered and causes all registers to be set to an initial state. The initial state is determined by the device control pins as described in the [Device Configuration Control](#) section. When PDN is pulled low, I<sup>2</sup>C is disabled. When PDN is pulled high, the device power-up sequence is initiated as described in [Device Power Up Sequence](#) and [Device Power Up Timing](#).

**Table 21. PDN Control**

| PDN Pin State | Device operation   |
|---------------|--------------------|
| 0             | Device is disabled |
| 1             | Normal operation   |

### 12.4 Power Rail Sequencing, Power Supply Ramp Rate, and Mixing Supply Domains

#### 12.4.1 Mixing Supplies

The LMK03318 incorporates flexible power supply architecture. TI recommends driving the VDD\_IN, VDD\_PLL, VDD\_LDO, and VDD\_DIG supplies by the same 3.3-V supply rail, but the individual VDDO\_x supplies can be driven from separate 1.8-V, 2.5-V, or 3.3-V supply rails. Lowest power consumption can be realized by operating the VDD\_IN, VDD\_PLL, VDD\_LDO, and VDD\_DIG supplies from a 3.3-V rail and the VDDO\_x supplies from a 1.8-V rail.

#### 12.4.2 Power-On Reset

The LMK03318 integrates a built-in power-on reset (POR) circuit, that holds the device in reset until all of the following conditions have been met:

- the VDD\_IN, VDD\_PLL, VDD\_LDO, or VDD\_DIG supplies have reached at least 2.72 V
- the VDDO\_01 supply has reached at least 1.7 V
- the PDN pin has reached at least 1.2 V

After this POR release, device internal counters start (see [Device Power Up Timing](#)) followed by device calibration.

#### 12.4.3 Powering Up From Single-Supply Rail

If the VDD\_IN, VDD\_PLL, VDD\_LDO, VDD\_DIG, and VDDO supplies are driven by the same 3.3-V supply rail that ramp in a monotonic manner from 0 V to 3.135 V, irrespective of the ramp time, then there is no requirement to add a capacitor on the PDN pin to externally delay the device power-up sequence. As shown in [Figure 83](#), the PDN pin can be left floating, pulled up externally to VDD, or otherwise driven by a host controller for meeting the clock sequencing requirements in the system.

## Power Rail Sequencing, Power Supply Ramp Rate, and Mixing Supply Domains (continued)

**Figure 83. Recommendations for Power Up From Single-Supply Rail**

### 12.4.4 Powering Up From Split-Supply Rails

If the VDD\_IN, VDD\_PLL, VDD\_LDO, VDD\_DIG, and VDDO supplies are driven from different supply rails, TI recommends starting the device POR sequence after all core and output supplies have reached their minimum voltage tolerances (VDD ≥ 3.135 V and VDDO ≥ 1.71 V). This can be realized by delaying the PDN low-to-high transition. The PDN input incorporates a 200-kΩ resistor to VDDO\_01 and as shown in [Figure 84](#), a capacitor from the PDN pin to GND can be used to form a R-C time constant with the internal pullup resistor or an external pullup resistor. This R-C time constant can be designed to delay the low-to-high transition of PDN until all core and output supplies have reached their minimum voltage tolerances. Alternatively, the delayed PDN low-to-high transition could be controlled by a logic output of a host controller (CPLD/FPGA/CPU) or power sequencer.

**Figure 84. Recommendations for Power Up From Split-Supply Rails**

### 12.4.5 Slow Power-Up Supply Ramp

In case the VDD\_IN, VDD\_PLL, VDD\_LDO, and VDD\_DIG, and VDDO supplies ramp slowly with a ramp time over 100 ms, TI recommends starting the device POR sequence after all core and output supplies have reached their minimum voltage tolerances (VDD ≥ 3.135 V and VDDO ≥ 1.71 V). This can be realized by delaying the PDN low-to-high transition in a manner similar to the condition detailed in [Powering Up From Split-Supply Rails](#) and shown in [Figure 84](#).

## Power Rail Sequencing, Power Supply Ramp Rate, and Mixing Supply Domains (continued)

If a VDD supply cannot reach 3.135 V before the PDN low-to-high transition, TI recommends toggling the PDN pin again or chip soft reset bit in R12.7 after all VDD and VDDO supplies reached their minimum tolerances to re-trigger the device POR sequence for normal chip operation.

If only VDDO supplies ramp after the PDN low-to-high transition, issuing a channel reset on any PLL-driven output channel with its PLL SYNC enabled (PLL\_SYNC\_EN=1) is recommended to ensure normal output divider operation without requiring a full chip reset (through PDN pin or soft reset). A local channel reset can be issued by toggling the corresponding power-down bit(s) in R30 after its VDDO supply has reached 1.71 V. Alternatively, an output SYNC can be issued to reset any SYNC-enabled channel (see [Output Synchronization](#)).

### 12.4.6 Non-Monotonic Power-Up Supply Ramp

In case the VDD\_IN, VDD\_PLL, VDD\_LDO, VDD\_DIG, and VDDO supplies ramp in a non-monotonic manner, TI recommends starting the device POR sequence after all core and output supplies have reached their minimum voltage tolerances ( $VDD \geq 3.135$  V and  $VDDO \geq 1.71$  V). This can be realized by delaying the PDN low-to-high transition in a manner similar to the condition detailed in [Powering Up From Split-Supply Rails](#) and shown in [Figure 84](#).

### 12.4.7 Slow Reference Input Clock Startup

If the reference input clock is direct coupled to the LMK03318 and has a very slow startup time of over 10 ms, as defined from the time power supply reaches acceptable operating voltage for the reference input generator, which is typically 2.97 V for a 3.3-V supply, to the time when the reference input has a stable clock output, take additional care to prevent unsuccessful PLL calibration. In the case of the reference input building up its amplitude slowly, TI recommends setting the input buffer to differential irrespective of the input type (LVCMOS or differential). In case of LVCMOS inputs, TI also recommends enabling on-chip termination by setting R29.4 (for primary input) and/or R29.5 (for secondary input) to 1. There is one of two additional steps that need to be taken. The first approach is to add a capacitor to GND on the PDN pin that forms a R-C time constant with the internal 200-k $\Omega$  pullup resistor. This R-C time constant can be designed to delay the low-to-high transition of PDN, until after the reference input clock is stable. The second approach is to program a larger PLL closed loop delay in R119[3-2] that is longer than the time taken for the reference input clock to be stable.

## 12.5 Power Supply Bypassing

[Figure 85](#) shows two conceptual layouts detailing recommended placement of power supply bypass capacitors. If the capacitors are mounted on the back side, 0402 components can be employed; however, soldering to the Thermal Dissipation Pad can be difficult. For component side mounting, use 0201 body size capacitors to facilitate signal routing. Keep the connections between the bypass capacitors and the power supply on the device as short as possible. Ground the other side of the capacitor using a low impedance connection to the ground plane.

## Power Supply Bypassing (continued)

Back Side

Component Side

## 13 Layout

### 13.1 Layout Guidelines

The following section provides the layout guidelines to ensure good thermal and electrical performance for the LMK03318.

#### 13.1.1 Ensure Thermal Reliability

The LMK03318 is a high performance device. Therefore, pay careful attention to device configuration and printed-circuit board (PCB) layout with respect to device power consumption and thermal considerations. Employing a thermally-enhanced PCB layout can insure good thermal dissipation from the device to the PCB layers. Observing good thermal layout practices enables the thermal slug, or die attach pad (DAP), on the bottom of the 48-pin WQFN package to provide a good thermal path between the die contained within the package and the ambient air through the PCB interface. This thermal pad also serves as the singular ground connection the device; therefore, a low-inductance connection to multiple PCB ground layers (both internal and external) is essential.

#### 13.1.2 Support for PCB Temperature up to 105°C

The LMK03328 can maintain a safe junction temperature below the recommended maximum value of 125°C even when operated on a PCB with a maximum board temperature ( $T_b$ ) of 105°C. This can shown by the following example calculation, assuming a worst-case device current consumption from [Electrical Characteristics - Power Supply](#) and the thermal data in [Thermal Information](#) using a 4-layer JEDEC test board with no airflow.

$$T_J = T_b + (\psi_{jb} \times P_{d_{max}}) = 117.6^\circ\text{C}$$

where

- $T_b = 105^\circ\text{C}$
- $\psi_{jb} = 4.02^\circ\text{C/W}$
- $P_{d_{max}} = I_{DD} \times V_{DD} = 952 \text{ mA} \times 3.3 \text{ V} = 3.14 \text{ W}$  (6)

### 13.2 Layout Example

[Figure 86](#) shows a PCB layout example showing the application of thermal design practices and low-inductance ground connection between the device DAP and the PCB. Connecting a 6 x 6 thermal via pattern and using multiple PCB ground layers (for example, 8- or 10-layer PCB) can help to reduce the junction-to-ambient thermal resistance, as indicated in the [Thermal Information](#) section. The 6 x 6 filled via pattern facilitates both considerations.

## Layout Example (continued)

**Figure 86. 4-Layer PCB Thermal Layout Example for LMK03318 (8+ Layers Recommended)**

## 14 デバイスおよびドキュメントのサポート

### 14.1 デバイス・サポート

#### 14.1.1 デベロッパー・ネットワークの製品に関する免責事項

デベロッパー・ネットワークの製品またはサービスに関するTIの出版物は、単独またはTIの製品、サービスと一緒に提供される場合に関係なく、デベロッパー・ネットワークの製品またはサービスの適合性に関する是認、デベロッパー・ネットワークの製品またはサービスの是認の表明を意味するものではありません。

### 14.2 ドキュメントの更新通知を受け取る方法

ドキュメントの更新についての通知を受け取るには、[ti.com](http://ti.com)のデバイス製品フォルダを開いてください。右上の隅にある「通知を受け取る」をクリックして登録すると、変更されたすべての製品情報に関するダイジェストを毎週受け取れます。変更の詳細については、修正されたドキュメントに含まれている改訂履歴をご覧ください。

### 14.3 コミュニティ・リソース

The following links connect to TI community resources. Linked contents are provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

**TI E2E™ オンライン・コミュニティ** TIのE2E ( *Engineer-to-Engineer* ) コミュニティ。エンジニア間の共同作業を促進するために開設されたものです。e2e.ti.comでは、他のエンジニアに質問し、知識を共有し、アイデアを検討して、問題解決に役立てることができます。

<sup>(1)</sup> **Status:** For more details on status, see our [product life cycle](#).

<sup>(2)</sup> **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

<sup>(3)</sup> **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

<sup>(4)</sup> **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

<sup>(5)</sup> **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

<sup>(6)</sup> **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

**Important Information and Disclaimer:**The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
