

OPT4041 高速、デュアルチャネル、高精度、デジタル周辺光センサ

1 特長

- High speed I²C インターフェイスを使用した高精度の高速光 / デジタル変換
- 可視チャネル:
 - 優れた近赤外線 (IR) 除去機能により人間の目によく合致した高精度の光フィルタリングを実現
 - 28 ビットでの実効ダイナミックレンジ: 585μlux ~ 157klux
- 広帯域チャネル:
 - NIR を含む広範囲の波長に応答可能
 - 26 ビットでの実効ダイナミックレンジ: 192.3pW/cm² ~ 12.91mW/cm²
- 片対数出力:
 - 9 (可視チャネル) および 7 (WB チャネル) のバイナリ対数フルスケール光レンジ
 - 各範囲内で非常に線形的な応答
- 内蔵の自動フルスケール光レンジ選択ロジックにより、入力光条件に基づいて測定レンジを切り替え、常に可能な限り最高の分解能を実現
- 12 ステップの構成可能な変換時間:
 - チャンネルあたり 600μs ~ 800ms (高速、高精度アプリケーションに対応可能)
- ハードウェア同期トリガおよび割り込み用の外部ピン割り込み
- I²C バースト読み出し可能な出力レジスタの内部 FIFO
- 小さい動作電流: 30μA
- 超低消費電力スタンバイ時: 2μA
- 動作温度範囲: -40°C ~ +85°C
- 広い電源電圧範囲: 1.6V ~ 3.6V
- 5.5V 許容の I/O ピン
- I²C アドレスを選択可能
- 小さい外形:
 - 2.1mm × 1.9mm × 0.6mm SOT-5X3 パッケージ

2 アプリケーション

- IP ネットワーク カメラ
- ビデオドアベル
- アナログ セキュリティ カメラ
- ドア センサと窓センサ

パッケージ情報

部品番号	パッケージ (1)	パッケージ サイズ (2)
OPT4041	SOT-5X3 (8)	2.1mm × 1.9mm × 0.6mm

- (1) 詳細については、[セクション 11](#) を参照してください。
- (2) パッケージ サイズ (長さ × 幅) は公称値で、該当する場合はピンも含まれます。

OPT4041 の代表的なアプリケーション図

スペクトル応答 : OPT4041 と人間の目の比較

3 概要

OPT4041 は、2 つの独立したチャンネルで可視光の強度を測定する光 / デジタル センサ (シングル チップのルクス メーター) です。ALS チャンネルのスペクトル応答は人間の目の明所視応答によく合致します。一方、WB チャンネルのスペクトル応答は幅が広く、広範囲の光スペクトルを測定します。ALS チャンネルは特別に設計されたフィルタにより、一般的な光源から近赤外線成分を除去し、正確な光の強度を測定します。OPT4041 の出力は片対数で、バイナリ対数フルスケール光レンジと、各レンジ内での非常に線形な応答を備えています。可視チャンネルには 9 つのバイナリ光レンジがあり、 $585\mu\text{lux} \sim 157\text{klux}$ の測定能力と 28 ビットの実効ダイナミック レンジを実現します。広帯域チャンネルには 7 つの光レンジがあり、 $192.3\text{pW}/\text{cm}^2 \sim 12.91\text{mW}/\text{cm}^2$ の測定能力と 26 ビットの実効ダイナミック レンジを実現します。内蔵の自動レンジ選択ロジックにより、光レベルに基づいてデバイスのゲイン設定が動的に調整されるため、ユーザーの入力なしであらゆる条件下で可能な限り最高の分解能が得られます。

OPT4041 は、両方のチャンネルに工学的光学フィルタを搭載しており、強力な帯域外除去を実現します。可視チャンネルに強力な赤外線除去機能があるため、特に審美的な理由でセンサを暗色のガラス下に配置した場合に、あらゆる光源にわたって高いルクス精度を維持できます。WB チャンネルはスペクトル応答の範囲が広く、850nm および 940nm の NIR 波長を含む広範囲のスペクトル成分を測定できます。

OPT4041 は、ユーザーの使いやすさ向上のために光レベル検出機能を必要とするシステム向けに設計されており、通常、人間の目との一致度が低く近赤外線除去機能が劣る低精度のフォトダイオード、フォトレジスタ、その他の周辺光センサの代替品として利用できます。

OPT4041 デバイスは、12 ステップでチャンネル当たり $600\mu\text{s} \sim 800\text{ms}$ の光変換時間で動作するように設定でき、アプリケーションのニーズに応じたシステムの柔軟性を実現します。変換時間には、光の積分時間とアナログ / デジタル (ADC) 変換時間が含まれます。測定の分解能は、光の強度と積分時間の組み合わせによって決定され、実質的に最小 $585\mu\text{lux}$ までの光強度の変化を測定できます。

柔軟なデジタル動作により、システムの統合が可能です。連続的な測定も、レジスタ書き込みまたはハードウェアピンによる 1 回のみの測定も可能です。本デバイスは、スレッシュホールド検出ロジックを備えており、センサが適切なウェイクアップ イベントが割り込みピン経由で報告されるのを待機している間、プロセッサはスリープできます。

このセンサは、I²C および SMBus 互換の 2 線式シリアル インターフェイス上の光レベルを表すデジタル出力を報告します。出力レジスタの内部先入れ先出し (FIFO) を使用すると、センサからの測定値を低速で読み出すと同時に、デバイスでキャプチャされたすべてのデータを保持できます。また、OPT4041 は I²C バースト モードもサポートしており、ホストは最小限の I²C オーバーヘッドで FIFO からデータを読み取ることができます。

OPT4041 は、低い消費電力と低い電源電圧で動作するので、バッテリー駆動システムのバッテリー動作時間を延長できます。

表 4-1. Pin Functions

PIN		TYPE	DESCRIPTION
NO.	NAME		
1	VDD	Power	Device power. Connect to a 1.6V to 3.6V supply.
2	ADDR	Digital input	Address pin. This pin sets the LSBs of the I ² C address.
3	NC	No Connection	No Connection
4	GND	Power	Ground
5	SCL	Digital input	I ² C clock. Connect with a 10kΩ resistor to a 1.6V to 5.5V supply.
6	NC	No Connection	No Connection
7	INT	Digital I/O	Interrupt input/output open-drain. Connect with a 10kΩ resistor to a 1.6V to 5.5V supply.
8	SDA	Digital I/O	I ² C data. Connect with a 10kΩ resistor to a 1.6V to 5.5V supply.

5 Specifications

5.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
Voltage	VDD to GND	−0.5	6	V
	SDA and SCL to GND	−0.5	6	V
Current in to any pin			10	mA
T _J	Junction temperature		150	°C
T _{stg}	Storage temperature	−65	150 ⁽²⁾	°C

- (1) Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If used outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.
- (2) Long exposure to temperatures higher than 105°C can cause package discoloration, spectral distortion, and measurement inaccuracy.

5.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins ⁽¹⁾	±2000	V
		Charged device model (CDM), per ANSI/ESDA/JEDEC JS-002, all pins ⁽²⁾	±500	

- (1) JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

5.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
VDD	Supply voltage	1.6		3.6	V
T _J	Junction temperature	−40		85	°C

5.4 Thermal Information

THERMAL METRIC ⁽¹⁾		OPT4041	UNIT
		SOT-5X3 (DTS)	
		8 Pins	
R _{θJA}	Junction-to-ambient thermal resistance	112.2	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	28.4	°C/W
R _{θJB}	Junction-to-board thermal resistance	22.1	°C/W
Ψ _{JT}	Junction-to-top characterization parameter	1.2	°C/W
Ψ _{JB}	Junction-to-board characterization parameter	22	°C/W

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application note.

5.5 Electrical Characteristics

All specifications at TA = 25°C, VDD = 3.3V, 800ms conversion-time (CONVERSION_TIME=0xB), automatic full-scale range, white LED and normal-angle incidence of light, unless otherwise specified.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
OPTICAL						
	Number of channels			2		
	Peak irradiance spectral responsivity	CH0 (ALS)		561		nm
		CH1 (WB)		518		nm

E _v	Measurement output result for ALS Channel (CH0)	2000 lux input ⁽¹⁾	1800	2000	2200	lux
	Relative accuracy between gain ranges ⁽²⁾	All channels		0.6		%
E _{vIR}	Infrared response	850-nm near infrared, CH0 (ALS) response		0.2		%
	Light source variation for lux measurement (incandescent, halogen, fluorescent)	Bare device, no cover glass		4		%
	Linearity	EXPONENT_CHx > 0, 100ms conversion-time CT=8, all channels		2		%
		EXPONENT_CHx = 0, 100ms conversion-time CT=8, all channels		5		%
	Drift across temperature	All channels		0.01		%/°C
	Dark Measurement	All channels		0	10	codes
	Angular response (FWHM)	CH0 (ALS)		121		°
		CH1 (WB)		128		°
PSRR	Power-supply rejection ratio ⁽³⁾	VDD at 3.6V and 1.6V, all channels		0.1		%/V
POWER SUPPLY						
V _{DD}	Power supply		1.6		3.6	V
V _{I2C}	Power supply for I ² C pull up resistor	I ² C pullup resistor, V _{DD} ≤ V _{I2C}	1.6		5.5	V

All specifications at TA = 25°C, VDD = 3.3V, 800ms conversion-time (CONVERSION_TIME=0xB), automatic full-scale range, white LED and normal-angle incidence of light, unless otherwise specified.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
I _{QACTIVE}	Active Current	Dark		24		μA
		Full-scale lux		29		μA
I _Q	Quiescent current	Dark		2		μA
		Full-scale lux		2.6		μA
POR	Power-on-reset threshold			0.8		V
DIGITAL						
C _{IO}	I/O Pin Capacitance			3		pF
T _{ss}	Trigger to Sample Start	Low-power shutdown mode		0.5		ms
V _{IL}	Low-level input voltage (SDA, SCL, and ADDR)		0		0.3 X V _{DD}	V
V _{IH}	High-level input voltage (SDA, SCL, and ADDR)		0.7 X V _{DD}		5.5	V
I _{IL}	Low-level input current (SDA, SCL, and ADDR)			0.01	0.25 ⁽⁵⁾	μA
V _{OL}	Low-level output voltage (SDA and INT)	I _{OL} =3mA			0.32	V
I _{ZH}	Output logic high, high-Z leakage current (SDA, INT)	Measured with V _{DD} at pin		0.01	0.25 ⁽⁵⁾	μA
TEMPERATURE						
	Specified temperature range		–40		85	°C

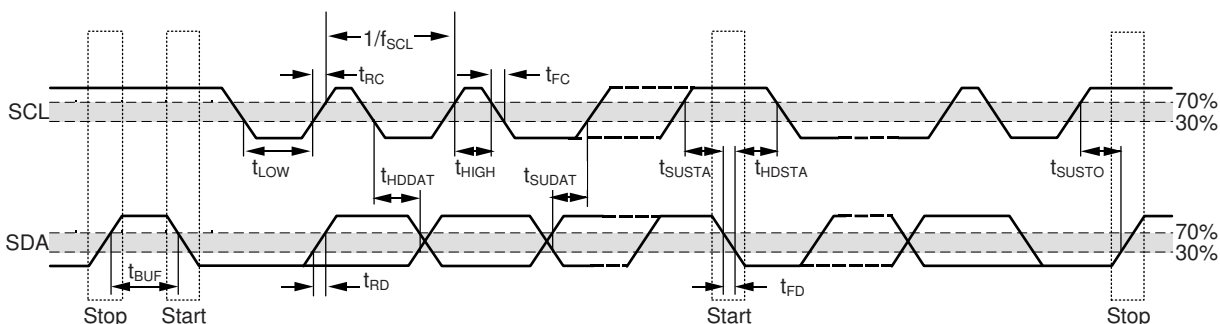

- (1) Tested with the white LED calibrated to 2000lux
- (2) Characterized by measuring fixed near-full-scale light levels on the higher adjacent full-scale range setting.
- (3) PSRR is the percent change of the measured lux output from its current value, divided by the change in power supply voltage, as characterized by results from 3.6V and 1.6V power supplies
- (4) The conversion-time, from start of conversion until the data are ready to be read, is the integration-time plus analog-to-digital conversion-time.
- (5) The specified leakage current is dominated by the production test equipment limitations. Typical values are much smaller

5.6 I²C Interface Timing Requirements

All timing parameters are referenced to low and high voltage thresholds of 30% and 70%, respectively, of the final settled value.

		MIN	TYP	MAX	UNIT
I²C FAST MODE					
f _{SCL}	Clock operating frequency	0.01		0.4	MHz
t _{BUF}	Bus free time between stop and start	1300			ns
t _{HDSTA}	Hold time after repeated start	600			ns
t _{SUSTA}	Setup time for repeated start	600			ns
t _{SUSTO}	Setup time for stop	600			ns
t _{HDDAT}	Data hold time	20		900	ns
t _{SUDAT}	Data setup time	100			ns
t _{LOW}	Clock low period	1300			ns
t _{HIGH}	Clock high period	600			ns
t _{RC} and t _{FC}	Clock rise and fall time			300	ns
t _{RD} and t _{FD}	Data rise and fall time			300	ns
t _{TIMEO}	Bus timeout period. If the clock line is held low for this duration of time, the bus state machine is reset.		28		ms
I²C HIGH-SPEED MODE					
f _{SCL}	Clock operating frequency	0.01		2.6	MHz
t _{BUF}	Bus free time between stop and start	160			ns
t _{HDSTA}	Hold time after repeated start	160			ns
t _{SUSTA}	Setup time for repeated start	160			ns
t _{SUSTO}	Setup time for stop	160			ns
t _{HDDAT}	Data hold time	20		140	ns
t _{SUDAT}	Data setup time	20			ns
t _{LOW}	Clock low period	240			ns
t _{HIGH}	Clock high period	60			ns
t _{RC} and t _{FC}	Clock rise and fall time			40	ns
t _{RD} and t _{FD}	Data rise and fall time			80	ns
t _{TIMEO}	Bus timeout period. If the clock line is held low for this duration of time, the bus state machine is reset.		28		ms

6 Detailed Description

6.1 Overview

OPT4041 measures the ambient light that illuminates the device. This device measures light with a spectral response very closely matched to the human eye, and with excellent infrared rejection.

Matching the sensor spectral response to that of the human eye response is vital because ambient light sensors are used to measure and help create ideal human lighting experiences. Strong rejection of infrared light, which a human does not see, is a crucial component of this matching. This matching makes the OPT4041 especially good for operation underneath windows that are visibly dark, but infrared transmissive.

The wide band channel is sensitive to a broad range of wavelengths, including 850nm and 940nm NIR wavelengths. This enables accurate measurement of a wide range of sources.

OPT4041 is fully self-contained to measure the ambient light and report the result in ADC codes directly proportional to lux digitally over the I²C bus. The result can also be used to alert a system and interrupt a processor with the INT pin. The result can also be summarized with a programmable threshold comparison and communicated with the INT pin.

OPT4041 is by default configured to operate in automatic full-scale range detection mode that always selects the optimal full-scale range setting for the given lighting conditions. There are 9 full-scale range settings one of which can be selected manually as well. Setting the device to operate in automatic full-scale range detection mode frees the user from having to program the software for potential iterative cycles of measurement and readjustment of the full-scale range until optimal for any given measurement. With device exhibiting excellent linearity over the entire 28 bit dynamic range of measurement no additional linearity calibration is required at system level.

OPT4041 can be configured to operate in continuous or one-shot measurement modes. The device offers 12 conversion times ranging from 600μs to 800ms. The device starts up in a low-power shutdown state, such that the OPT4041 only consumes active-operation power after being programmed into an active state.

OPT4041 optical filtering system is not excessively sensitive to non-ideal particles and micro-shadows on the optical surface. This reduced sensitivity is a result of the relatively minor device dependency on uniform density optical illumination of the sensor area for infrared rejection. Proper optical surface cleanliness is always recommended for best results on all optical devices.

6.2 Functional Block Diagram

図 6-1. Functional Block Diagram of OPT4041

6.3 Feature Description

6.3.1 Spectral Response

6.3.1.1 Channel 0: Human Eye Matching

The OPT4041 spectral response closely matches that of the human eye. If the ambient light sensor measurement is used to help create a good human experience, or create optical conditions that are optimal for a human, the sensor must measure the same spectrum of light that a human sees.

The OPT4041 also has excellent infrared light (IR) rejection. This IR rejection is especially important because many real-world lighting sources have significant infrared content that humans do not see. If the sensor measures infrared light that the human eye does not see, then a true human experience is not accurately represented.

If the application demands hiding the OPT4041 underneath a dark window (such that the end-product user cannot see the sensor) the infrared rejection of the OPT4041 becomes significantly more important because many dark windows attenuate visible light but transmit infrared light. This attenuation of visible light and lack of attenuation of IR light amplifies the ratio of the infrared light to visible light that illuminates the sensor. Results can still be well matched to the human eye under this condition because of the high infrared rejection of the OPT4041.

6.3.1.2 Channel 1: Wide Band

Channel 1 of the OPT4041 has a wide spectral bandwidth, ranging from 380nm to 1000nm. The wide band channel enables the OPT4041 to perform measurements in applications with a variety of wavelengths, and the NIR response can be useful for monitoring IR LEDs or performing overall system calibrations. For example, the channel 1 NIR measurements can be used in systems where fast calibration of camera exposure settings is required.

6.3.2 Automatic Full-Scale Range Setting

The OPT4041 has an automatic full-scale range setting feature that eliminates the need to predict and set the optimal range for the device. In this mode, the device automatically selects the optimal full-scale range for varying lighting condition each measurement. The device has a high degree of result matching between the full-scale range settings. This matching eliminates the problem of varying results or the need for range-specific, user-calibrated gain factors when different full-scale ranges are chosen.

6.3.3 Output Register CRC and Counter

The OPT4041 device features additional bits as part of the output register which helps in improving the reliability of light measurements for the application.

6.3.3.1 Output Sample Counter

The OPT4041 device features **COUNTER** registers as part of the output registers for both channels which increment for every successful measurement. These registers can be read as part of the output registers which helps the application to keep track of measurements. The 4 bit counter starts at 0 on power-up and counts up to 15 after which the counter resets back to 0 and continues to count up. This is particularly helpful in situations such as the following:

- Host or Controller needs consecutive measurements. Utilizing the **COUNTER** registers, the controller can compare samples and verifies that the samples are in expected order without missing intermediate counter values.
- As a safety feature when the light level is not changing, the controller can verify that the measurements from OPT4041 are not stuck by comparing values of the **COUNTER** registers between measurements. If the COUNTER values continue to change over samples, the device updates the output register with the most recent measurement of light levels.

6.3.3.2 Output CRC

The CRC register consists of Cyclic Redundancy Checker bits as part of the output registers calculated within the OPT4041 device and is updated on every measurement. This feature helps in detecting communication related bit errors during the output readout from the device. [Register 1h](#) lists the calculation method for the CRC bits, which can be independently verified in the controller or host firmware and software to validate if communication between the controller and the device is successful without bit errors during transmission.

6.3.4 Threshold Detection

OPT4041 features a threshold detection logic which can be programmed to indicate and update register flags if measured light levels cross thresholds set by the user. The threshold condition can be programmed to use one of the two channels as a trigger, as determined by the [THRESHOLD_CH_SEL](#) register. There are independent low and high threshold target registers with independent flag registers to indicate the status of measured light level. Measured light levels reaching below the low threshold and above the high threshold are called faults. Users can program a fault count register, which counts consecutive number of faults before the flag registers are set. This is particularly useful in cases where the controller can read the flag register alone to get an indication of the measured light level without needing to perform lux calculations. Calculations for setting up the threshold are available in the [セクション 6.4.6](#) section.

6.4 Device Functional Modes

6.4.1 Modes of Operation

The OPT4041 has the following modes of operation:

- **Power-down mode:** This mode is a power-down or standby mode where the device enters a low-power state. There is no active light sensing or conversion in this mode. The device still responds to I²C transactions that can be used to bring the device out of this mode. The OPERATING_MODE register is set to 0.
- **Continuous mode:** In this mode, the OPT4041 measures and updates the output registers continuously as determined by the conversion time and generates a hardware interrupt on the INT pin for every successful conversion. Configure the INT pin in output mode using the INT_DIR register. The device active circuits are continuously kept active to minimize the interval between measurements. The OPERATING_MODE register is set to 3.
- **One-shot mode:** There are two ways in which the OPT4041 can be used in one-shot mode of operation with one common theme where the OPT4041 stays in standby mode and a conversion is triggered either by a register write to the configuration register or by a hardware interrupt on the INT pin.

There are two types of one-shot modes.

- **Force auto-range one-shot mode:** Every one-shot trigger forces a full reset on the auto-ranging control logic and a fresh auto-range detection is initiated, ignoring the previous measurements. This mode is particularly useful in situations where lighting conditions are expected to change frequently and the conditions for the one-shot trigger frequency are not expected to change very often. There is a small penalty on conversion time resulting from the auto-ranging logic recovering from a reset state. The full reset cycle on the auto-ranging control logic takes approximately 500µs, which must be accounted for between measurements when this mode is used. The OPERATING_MODE register is set to 1.
- **Regular auto-range one-shot mode:** Auto-range selection logic uses the information from the previous measurements to determine the range for the current trigger. Only use this mode when the device needs time-synchronized measurements with frequent triggers from the controller. In other words, this mode can be used as an alternative to continuous mode. The key difference between these modes is that the interval between measurements is determined by the one-shot triggers. The OPERATING_MODE register is set to 2.

One-shot mode can be triggered by the following:

- **Hardware trigger:** The INT pin can be configured as an input to trigger a measurement, setting the INT_DIR register to 0. When the INT pin is used as input, there is no hardware interrupt to indicate

completion of measurement. The controller must keep time from the trigger mechanism and read out output registers.

- **Register trigger:** An I²C write to the OPERATING_MODE register triggers a measurement (value of 1 or 2). The register value is reset after the next successful measurement. The INT pin can be configured to indicate measurement completion to read out the output registers by setting the INT_DIR register to 1.

The interval between subsequent triggers must be set to account for all aspects involved in the trigger mechanism, such as the I²C transaction time, device wake-up time, auto-range time (if used), and device conversion time. If a conversion trigger is received before the completion of the current measurement, the device simply ignores the new request until the previous conversion is completed.

The device enters standby after each one-shot trigger; therefore, the measurement interval in the one-shot trigger mechanism must account for additional time (t_{ss} time, as specified in *Specifications* for the circuits to recover from standby state. However, setting the quick wake-up register QWAKE eliminates the need for this additional t_{ss} at the cost of not powering down the active circuit with the device not entering standby mode between triggers.

☒ 6-2 illustrates a timing diagram of the various operating modes.

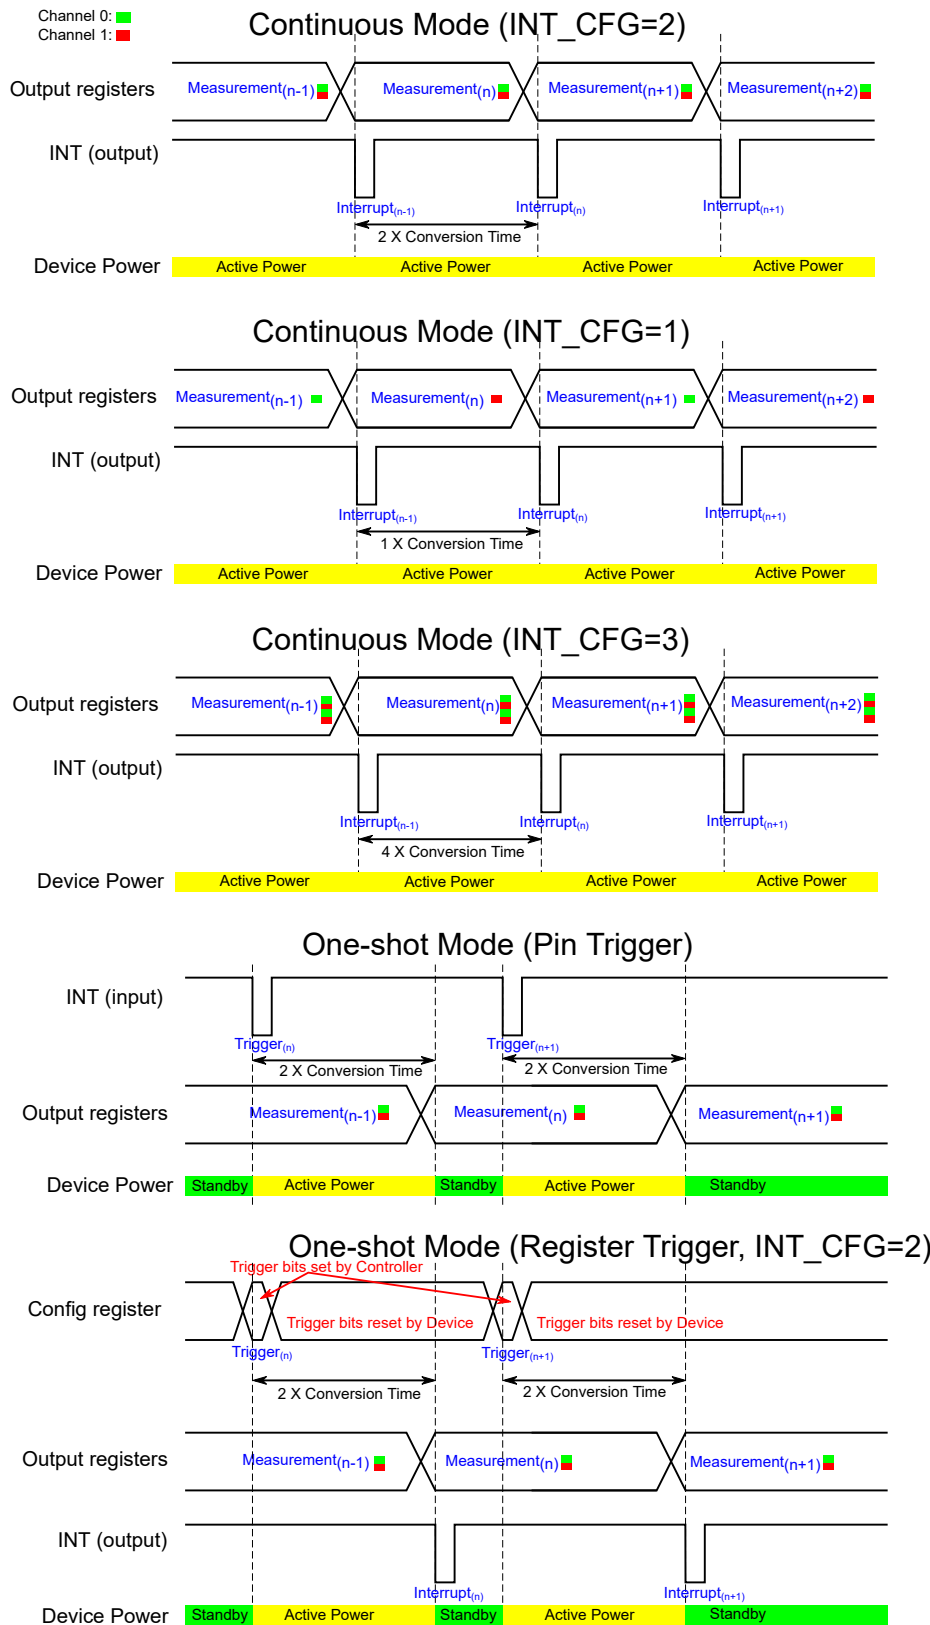

図 6-2. Timing Diagrams for Different Operating Modes

6.4.2 Interrupt Modes of Operation

The device has an interrupt reporting system that allows the processor connected to the I²C bus to go to sleep, or otherwise ignore the device results, until a user-defined event occurs that requires possible action. Alternatively, this same mechanism can also be used with any system that can take advantage of a single digital signal that indicates whether the light is above or below levels of interest.

The INT pin has an open-drain output, which requires the use of a pullup resistor. This open-drain output allows multiple devices with open-drain INT pins to be connected to the same line, thus creating a logical *NOR* or *AND* function between the devices. The polarity of the INT pin can be controlled by the [INT_POL](#) register.

There are two major types of interrupt reporting mechanism modes: latched window comparison mode and transparent hysteresis comparison mode. The [LATCH](#) configuration register controls which of these two modes is used. [図 6-3](#) and [表 6-1](#) summarize the function of these two modes. Additionally, the INT pin can either be used to indicate a fault in one of these modes ([INT_CFG](#) = 0) or to indicate a conversion completion ([INT_CFG](#) > 0). [表 6-2](#) details this functionality.

図 6-3. Interrupt Pin Status (INT_CFG = 0 Setting) and Register Flag Behavior

表 6-1. Interrupt Pin Status (INT_CFG = 0 Setting) and Register Flag Behavior

LATCH SETTING	INT PIN STATE (WHEN INT_CFG=0)	FLAG_H VALUE	FLAG_L VALUE	LATCHING BEHAVIOR
0: Transparent hysteresis mode	The INT pin indicates if measurement is above (INT active) or below (INT inactive) the threshold. If measurement is between the high and low threshold values, then the previous INT value is maintained. This mode prevents the INT pin from repeated toggling when the measurement values are close to the threshold.	0: If measurement is below the low limit 1: If measurement is above the high limit If measurement is between the high and low limits, the previous value is maintained.	0: If measurement is above the high limit 1: If measurement is below the low limit If measurement is between the high and low limits, the previous value is maintained.	Not latching: Values are updated after each conversion
1: Latched window mode	The INT pin becomes active if the measurement is outside the window (above the high threshold or below the low threshold). The INT pin does not reset and returns to the inactive state until the 0xC is register read.	1: If measurement is above the high limit	1: If measurement is below the low limit	Latching: The INT pin, FLAG_H, and FLAG_L values do not reset until the 0xC register is read.

The THRESHOLD_H, THRESHOLD_L, LATCH, and FAULT_COUNT registers control the interrupt behavior. As shown in 表 6-1, the LATCH field setting provides a choice between the latched window mode and transparent hysteresis mode. Interrupt reporting can be observed on the INT pin, the FLAG_H, and the FLAG_L registers.

Results from comparing the current sensor measurements with the THRESHOLD_H and THRESHOLD_L registers are referred to as *fault events*. See the セクション 6.4.6 section for the calculations to set these registers. The FAULT_COUNT register dictates the number of continuous *fault events* required to trigger an interrupt event and subsequently change the state of the interrupt reporting mechanisms. For example, with a FAULT_COUNT value of 2 corresponding to four fault counts, the INT pin, FLAG_H, and FLAG_L states shown in 図 6-3 are not realized unless four consecutive measurements are taken that satisfy the fault condition.

The INT pin function listed in 図 6-3 is valid only when INT_CFG = 0. As described in 表 6-2, the INT pin function can be changed to indicate an end of conversion or FIFO full state. The FLAG_H and FLAG_L registers continue to behave as listed in 図 6-3, even while INT_CFG > 0. The polarity of the INT pin is controlled by the INT_POL register.

表 6-2. INT_CFG Setting and Resulting INT Pin Behavior

INT_CFG SETTING	INT PIN FUNCTION
0	As per 図 6-3
1	INT pin asserted with a 1μs pulse duration after every conversion
2	INT pin asserted with a 1μs pulse duration every two conversions to indicate both channel measurements are complete
3	INT pin asserted with a 1μs pulse duration every four conversions to indicate the FIFO is full

6.4.3 Light Range Selection

The OPT4041 has an automatic full-scale-range setting mode that eliminates the need for a user to predict and set the optimal range for the device. Set the RANGE register to 0xC to enter this mode. The device determines the appropriate full-scale range to take the measurement based on a combination of current lighting conditions and the previous measurement.

If a measurement is towards the low side of full-scale, then the full-scale range is decreased by one or two settings for the next measurement. If a measurement is towards the upper side of full-scale, the full-scale range is increased by one setting for the next measurement.

If the measurement exceeds the full-scale range, resulting from a fast increasing optical transient event, the current measurement is aborted. This invalid measurement is not reported. If the scale is not at the maximum, the device increases the scale by one step and a new measurement is retaken with that scale. Therefore, during a fast increasing optical transient in this mode, a measurement can possibly take longer to complete and report than indicated by the [CONVERSION_TIME](#) configuration register.

Using this feature is highly recommended because the device selects the best range setting based on lighting conditions. However, there is an option to manually set the range. Setting the range manually turns off the automatic full-scale selection logic and the device operates for a particular range setting. [表 6-3](#) lists the range selection settings.

表 6-3. Range Selection Table

RANGE register setting	CH0 Typical Full-Scale Light Level	CH0 Exponent	CH1 Typical Full-Scale Light Level	CH1 Exponent
0	613lux	0	0.202mW/cm ²	0
1	1227lux	1	0.403mW/cm ²	1
2	2454lux	2	0.807mW/cm ²	2
3	4907lux	3	1.61mW/cm ²	3
4	9815lux	4	3.23mW/cm ²	4
5	19629lux	5	6.45mW/cm ²	5
6	39259lux	6	12.91mW/cm ²	6
7	78517lux	7	12.91mW/cm ²	6
8	157035lux	8	12.91mW/cm ²	6
12	Determined by automatic full-scale range logic; sets channel 0 and channel 1 independently			

6.4.4 Selecting Conversion Time

As listed in [表 6-4](#), the OPT4041 offers several conversion times that can be selected. Conversion time is defined as the time taken from initiation to completion of one measurement, including the time taken to update the results in the output register. Measurement initiation is determined by the mode of operation, as specified in [セクション 6.4.1](#).

表 6-4. Conversion Time Selection

CONVERSION_TIME register	Typical Conversion time
0	0.6ms
1	1ms
2	1.8ms
3	3.4ms
4	6.5ms
5	12.7ms
6	25ms
7	50ms
8	100ms
9	200ms
10	400ms
11	800ms

6.4.5 Light Measurement in Lux

The OPT4041 measures light and updates output registers with proportional ADC codes. The output of the device is represented by two parts: by four EXPONENT register bits and by 20 MANTISSA bits. This arrangement of binary logarithmic full-scale ranges with linear representation in a range helps cover a large dynamic range of measurements. MANTISSA represents the linear ADC codes proportional to the measured light within a given full-scale range and the EXPONENT bits represent the current full-scale range selected. The selected range can either be automatically determined by the auto-range selection logic or manually selected as per 表 6-3

The lux level can be determined using the following equations. First, use Equation 1 or Equation 2 to calculate the MANTISSA. Next, use Equation 3 or Equation 4 to calculate the ADC_CODES. Finally, use Equation 5 to calculate the lux.

$$\text{MANTISSA} = (\text{RESULT_MSB} \ll 8) + \text{RESULT_LSB} \quad (1)$$

or

$$\text{MANTISSA} = (\text{RESULT_MSB} \times 2^8) + \text{RESULT_LSB} \quad (2)$$

where:

- The RESULT_MSB, RESULT_LSB, and EXPONENT bits are parts of the output register

The RESULT_MSB register carries the most significant 12 bits of the MANTISSA, and the RESULT_LSB register carries the least significant eight bits of the MANTISSA. Use the previous equations to get the 20-bit MANTISSA number. The four EXPONENT bits are directly read from the register.

After the EXPONENT and MANTISSA portions are calculated, use Equation 3 or Equation 4 to calculate the linearized ADC_CODES.

$$\text{ADC_CODES} = (\text{MANTISSA} \ll E) \quad (3)$$

or

$$\text{ADC_CODES} = (\text{MANTISSA} \times 2^E) \quad (4)$$

The maximum value for register E is 8, thus the ADC_CODES is effectively a 28-bit number. As shown in Equation 5, the semi-logarithmic numbers are converted to a linear ADC_CODES representation, which is simple to convert to lux.

$$\text{lux} = \text{ADC_CODES} \times 585\text{E-}6 \quad (5)$$

The MANTISSA and ADC_CODES are large numbers with 20 and 28 bits required to represent them. While developing firmware or software for these calculations, allocating appropriate data types to prevent data overflow is important. Some explicit typecasting to a larger data type is recommended, such as 32-bit representation before a left-shift operation (<<).

6.4.6 Threshold Detection Calculations

The THRESHOLD_H_RESULT and THRESHOLD_L_RESULT threshold result registers are 12 bits, whereas the THRESHOLD_H_EXPONENT and THRESHOLD_L_EXPONENT threshold exponent registers are four bits. The threshold is compared at linear ADC_CODES, as given by the following equations. Therefore, the threshold registers are padded with zeros internally to compare with the ADC_CODES.

$$\text{ADC_CODES_TH} = \text{THRESHOLD_H_RESULT} \ll (8 + \text{THRESHOLD_H_EXPONENT}) \quad (6)$$

or

$$\text{ADC_CODES_TH} = \text{THRESHOLD_H_RESULT} \times 2^{(8 + \text{THRESHOLD_H_EXPONENT})} \quad (7)$$

and

$$\text{ADC_CODES_TL} = \text{THRESHOLD_L_RESULT} \ll (8 + \text{THRESHOLD_L_EXPONENT}) \quad (8)$$

or

$$\text{ADC_CODES_TL} = \text{THRESHOLD_L_RESULT} \times 2^{(8 + \text{THRESHOLD_L_EXPONENT})} \quad (9)$$

Threshold are then compared as given in the following equations to detect *fault events*.

$$\text{If } \text{ADC_CODES} < \text{ADC_CODES_TL} \text{ a } \textit{fault low} \text{ is detected} \quad (10)$$

and

$$\text{If } \text{ADC_CODES} > \text{ADC_CODES_TH} \text{ a } \textit{fault high} \text{ is detected} \quad (11)$$

Based on the FAULT_COUNT register setting, with consecutive *fault high* or *fault low* events, the respective FLAG_H and FLAG_L registers are set. See the [Interrupt Modes of Operation](#) section for more information. Understanding the relation between the THRESHOLD_H_EXPONENT, THRESHOLD_H_RESULT, THRESHOLD_L_EXPONENT, and THRESHOLD_L_RESULT register bits and the output registers is important to set the appropriate threshold based on application needs.

6.4.7 Light Resolution

The effective resolution of the OPT4041 is dependent on both the conversion time setting and the full-scale light range. Although the LSB resolution of the linear ADC_CODES does not change, the effective or useful resolution of the device is dependent (as per [表 6-5](#)) on the conversion time setting and the full-scale range. In conversion times where the effective resolution is lower, the LSBs are padded with 0.

表 6-5. Channel 0 Resolution Table

CONVERSION TIME REGISTER	CONVERSION TIME	MANTISSA EFFECTIVE BITS	EXPONENT								
			0	1	2	3	4	5	6	7	8

6.5 Programming

The OPT4041 supports the transmission protocol for standard mode (up to 100kHz), fast mode (up to 400kHz), and high-speed mode (up to 2.6MHz). Fast and standard modes are described as the default protocol, referred to as *F/S*. High-speed mode is described in the [High-Speed I²C Mode](#) section.

6.5.1 I²C Bus Overview

The OPT4041 offers compatibility with both I²C and SMBus interfaces. The I²C and SMBus protocols are essentially compatible with one another. The I²C interface is used throughout this document as the primary example with the SMBus protocol specified only when a difference between the two protocols is discussed.

The device is connected to the bus with two pins: an SCL clock input pin and an SDA open-drain bidirectional data pin. The bus must have a controller device that generates the serial clock (SCL), controls the bus access, and generates start and stop conditions. To address a specific device, the controller initiates a start condition by pulling the data signal line (SDA) from a high logic level to a low logic level while SCL is high. All targets on the bus shift in the target address byte on the SCL rising edge, with the last bit indicating whether a read or write operation is intended. During the ninth clock pulse, the target being addressed responds to the controller by generating an acknowledge bit by pulling SDA low.

Data transfer is then initiated and eight bits of data are sent, followed by an acknowledge bit. During data transfer, SDA must remain stable while SCL is high. Any change in SDA while SCL is high is interpreted as a start or stop condition. When all data are transferred, the controller generates a stop condition, indicated by pulling SDA from low to high while SCL is high. The device includes a 28ms timeout on the I²C interface to prevent locking up the bus. If the SCL line is held low for this duration of time, the bus state machine is reset.

6.5.1.1 Serial Bus Address

To communicate with the OPT4041, the controller must first initiate an I²C start command. Then, the controller must address target devices through a target address byte. The target address byte consists of a seven bit address and a direction bit that indicates whether the action is to be a read or write operation.

Four I²C addresses are possible by connecting the ADDR pin to one of four pins: GND, VDD, SDA, or SCL. 表 6-7 summarizes the possible addresses with the corresponding ADDR pin configuration. The state of the ADDR pin is sampled on every bus communication and must be driven or connected to the desired level before any activity on the interface occurs.

表 6-7. ADDR Pin Addresses

ADDR PIN CONNECTION	DEVICE I ² C ADDRESS
GND	1000100
VDD	1000101
SDA	1000110
SCL	1000111

6.5.1.2 Serial Interface

The OPT4041 operates as a target device on both the I²C bus and SMBus. Connections to the bus are made through the SCL clock input line and the SDA open-drain I/O line. The device supports the transmission protocol for standard mode (up to 100kHz), fast mode (up to 400kHz), and high-speed mode (up to 2.6MHz). All data bytes are transmitted most significant bits first.

The SDA and SCL pins feature integrated spike-suppression filters and Schmitt triggers to minimize the effects of input spikes and bus noise.

6.5.2 Writing and Reading

Accessing a specific register on the OPT4041 is accomplished by writing the appropriate register address during the I²C transaction sequence. See the [Register Maps](#) for a complete list of registers and the corresponding register addresses. The value for the register address (as shown in [図 6-4](#)) is the first byte transferred after the target address byte with the R/W bit low.

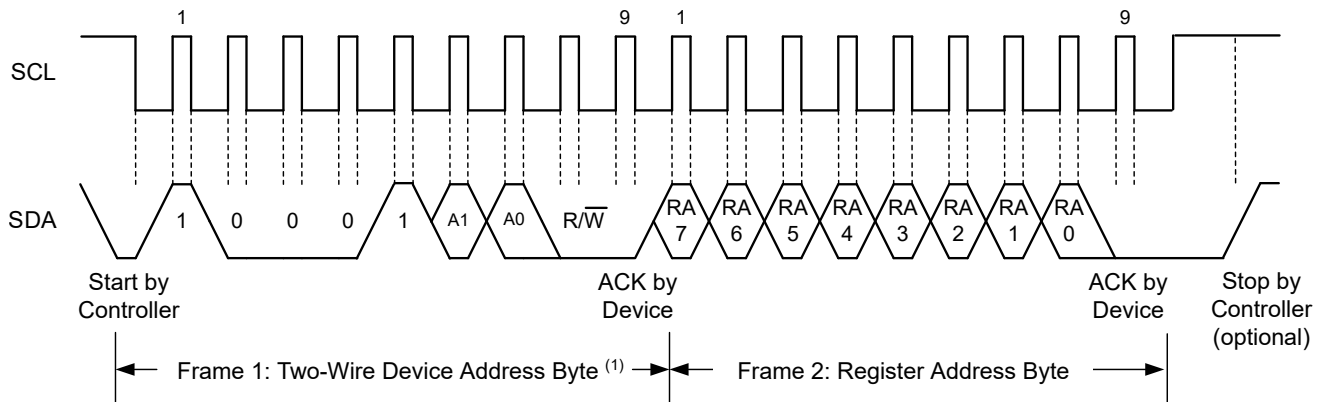

図 6-4. Setting the I²C Register Address

Writing to a register begins with the first byte transmitted by the controller. This byte is the target address with the R/W bit low. The device then acknowledges receipt of a valid address. The next byte transmitted by the controller is the address of the register that data are to be written to. The next two bytes are written to the register addressed by the register address. The device acknowledges receipt of each data byte. The controller can terminate the data transfer by generating a start or stop condition.

When reading from the device, the last value stored in the register address by a write operation determines which register is read during a read operation. To change the register address for a read operation, a new partial I²C write transaction must be initiated. This partial write is accomplished by issuing a target address byte with the R/W bit low, followed by the register address byte and a stop command. The controller then generates a start condition and sends the target address byte with the R/W bit high to initiate the read command. The next byte is transmitted by the target and is the most significant byte of the register indicated by the register address. This byte is followed by an acknowledge from the controller, then the target transmits the least significant byte. The controller acknowledges receipt of the data byte. The controller can terminate the data transfer by generating a not-acknowledge after receiving any data byte, or by generating a start or stop condition. If repeated reads from the same register are desired, continually sending the register address bytes is not necessary. The device retains the register address until that number is changed by the next write operation.

Figure 6-5 and Figure 6-6 show the write and read operation timing diagrams, respectively. Register bytes are sent most significant byte first, followed by the least significant byte.

图 6-5. I²C Write Example

A. An ACK by the controller can also be sent.

图 6-6. I²C Read Example

6.5.2.1 High-Speed I²C Mode

When the bus is idle, both the SDA and SCL lines are pulled high by the pullup resistors or active pullup devices. The controller generates a start condition followed by a valid serial byte containing the high-speed (HS) controller code 0000 1XXXb. This transmission is made in either standard mode or fast mode (up to 400kHz). The device does not acknowledge the HS controller code but does recognize the code and switches the internal filters to support a 2.6MHz operation.

The controller then generates a repeated start condition (a repeated start condition has the same timing as the start condition). After this repeated start condition, the protocol is the same as F/S mode, except that transmission speeds up to 2.6MHz are allowed. Instead of using a stop condition, use repeated start conditions to secure the bus in HS mode. A stop condition ends the HS mode and switches all internal filters of the device to support the F/S mode.

6.5.2.2 Burst Read Mode

The OPT4041 supports I²C burst read mode, which helps minimize the number of transactions on the bus for efficient data transfer from the device to the controller.

Before considering the burst mode, a regular I²C read transaction involves an I²C write operation to the device read pointer, followed by the actual I²C read operation. If regular I²C read transactions are performed when reading from the output registers and FIFO registers, which are in continuous locations, then the register pointer is written every two bytes and this process takes up several clock cycles. With the burst mode enabled, the read pointer address is auto incremented after every register read (two bytes), eliminating the need to write operations to set the pointer for subsequent register reads.

Set the I2C_BURST register to enable burst mode. When a stop command is issued, the pointer resets to the original register address before the auto-increments.  6-7 shows a diagram of the I²C write, single read, and burst mode read operation.

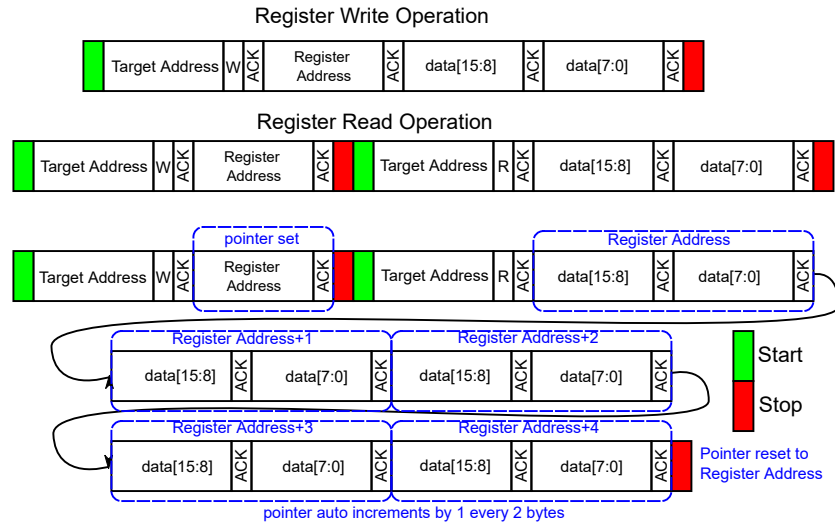

FIG 6-7. I²C Operations

6.5.2.3 General-Call Reset Command

The I²C general-call reset allows the host controller in one command to reset all devices on the bus that respond to the general-call reset command. Write to the I²C address 0 (0000 0000b) to initiate the general call. The reset command is initiated when the subsequent second address byte is 06h (0000 0110b). With this transaction, the device issues an acknowledge bit and sets all registers to the power-on-reset default condition.

8 Application and Implementation

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

8.1 Application Information

Because ambient light sensors are used in a wide variety of applications that require precise measurement of light as perceived by the human eye, these sensors have a specialized filter that mimics the human eye. The following sections show crucial information about integrating the OPT4041 in applications.

8.2 Typical Application

8.2.1 Electrical Interface

As shown in [Figure 8-1](#), the electrical interface is quite simple. Connect the OPT4041 I²C SDA and SCL pins to the same pins of an applications processor, microcontroller, or other digital processor. If that digital processor requires an interrupt resulting from an event of interest from the OPT4041, then connect the INT pin to either an interrupt or general-purpose I/O pin of the processor. There are multiple uses for this INT pin, including triggering a measurement on one-shot mode, signaling the system to wake up from low-power mode, processing other tasks while waiting for an ambient light event of interest, or alerting the processor that a sample is ready to be read. Connect pullup resistors between a power supply appropriate for digital communication and the SDA and SCL pins (because the pins have open-drain output structures). If the INT pin is used, connect a pullup resistor to the INT pin. A typical value for these pullup resistors is 10k Ω . The resistor choice can be optimized in conjunction to the bus capacitance to balance the system speed, power, noise immunity, and other requirements.

図 8-1. Typical Application Schematic

The power-supply and grounding considerations are discussed in the [セクション 8.4](#) section.

Although spike suppression is integrated in the SDA and SCL pin circuits, use proper layout practices to minimize the amount of coupling into the communication lines. One possible introduction of noise occurs from

capacitively coupling signal edges between the two communication lines. Another possible noise introduction comes from other switching noise sources present in the system, especially for long communication lines. In noisy environments, shield communication lines to reduce the possibility of unintended noise coupling into the digital I/O lines that can be incorrectly interpreted.

8.2.1.1 Design Requirements

This section describes the design requirements for a light sensor integrated into a system behind an enclosure cutout with a dark glass. This application is a common example of a light sensor system integration. Key considerations, such as sensor field of view (FoV) and dark glass transmission, are discussed in [セクション 8.2.1.1.1](#).

8.2.1.1.1 Optical Interface

図 8-2 shows the dimensions of the optical area. The gray area indicates the channel 0 photodiode and the white area indicates the channel 1 photodiode.

図 8-2. Sensor Position

Generally, any physical component that affects the light illuminating the sensing area of a light sensor also affects the performance of that light sensor. For example, a dark or opaque window can be used to further enhance the visual appeal of the design by hiding the sensor from view. This window material is typically transparent plastic or glass. Therefore, for the best performance, make sure to understand and control the effect of these components. Design a window width and height to permit light from a sufficient field of view to illuminate the sensor. For best performance, use a field of view of at least $\pm 35^\circ$, or preferably $\pm 45^\circ$ or more. Understanding and designing the field of view is discussed further in the [OPT3001: Ambient Light Sensor Application Guide application note](#).

The visible-spectrum transmission for dark windows typically ranges between 5% to 30%, but can be less than 1%. Specify a visible-spectrum transmission as low as, but no more than, necessary to achieve sufficient visual appeal because decreased transmission decreases the available light for the sensor to measure. The windows are made dark by either applying an ink to a transparent window material, or including a dye or other optical substance within the window material. This attenuating transmission in the visible spectrum of the window creates a ratio between the light on the outside of the design and the light that is measured by the device. To accurately measure the light outside of the design, compensate the device measurement for this ratio.

Although the inks and dyes of dark windows serve a primary purpose of being minimally transmissive to visible light, some inks and dyes can also be very transmissive to infrared light. The use of these inks and dyes further decreases the ratio of visible to infrared light, and thus decreases sensor measurement accuracy. However, because of the excellent red and infrared rejection of the device, this effect is minimized, and good results are achieved under a dark window with similar spectral responses.

For best accuracy, avoid grill-like window structures, unless the designer understands the optical effects sufficiently. These grill-like window structures create a nonuniform illumination pattern on the sensor that causes light measurement results to vary with placement tolerances and the angle of incidence of the light. If a grill-like structure is desired, then this device is an excellent sensor choice because the device is minimally sensitive to illumination uniformity issues disrupting the measurement process.

Light pipes can appear attractive for aiding in the optomechanical design that brings light to the sensor; however, do not use light pipes with any light sensor unless the system designer fully understands the ramifications of the optical physics of light pipes within the full context of the design and objectives.

8.2.1.2 Detailed Design Procedure

8.2.1.2.1 Optomechanical Design

After completing the electrical design, the next task is the optomechanical design. Window sizing and placement is discussed in more rigorous detail in the [OPT3001: Ambient Light Sensor Application Guide application note](#).

8.3 Best Design Practices

As with any optical product, take special care when handling the OPT4041. The optical surface of the device must be kept clean for the best performance, both when prototyping with the device and during mass production manufacturing procedures. Keep the optical surface clean of fingerprints, dust, and other optical-inhibiting contaminants. Use a properly-sized vacuum manipulation tool to handle the device.

If the optical surface of the device requires cleaning, then use a few gentle brushes with a soft swab of deionized water or isopropyl alcohol. Avoid potentially abrasive cleaning and manipulating tools and excessive force that can scratch the optical surface.

If the OPT4041 performance is diminished in any way, then inspect the optical surface for dirt, scratches, or other optical artifacts.

8.4 Power Supply Recommendations

Although the OPT4041 has low sensitivity to power-supply issues, good practices are always recommended. For best performance, the device VDD pin must have a stable, low-noise power supply with a 100nF bypass capacitor close to the device and solid grounding. There are many options for powering the device because of the device low current consumption levels.

8.5 Layout

8.5.1 Layout Guidelines

The PCB layout design for the OPT4041 requires a couple of considerations. Bypass the power supply with a capacitor placed close to the device. Note that optically reflective surfaces of components also affect the performance of the design. The three-dimensional geometry of all components and structures around the sensor must be taken into consideration to prevent unexpected results from secondary optical reflections. Placing capacitors and components at a distance of at least twice the height of the component is typically sufficient. The best optical layout is to place all close components on the opposite side of the PCB from the device. However, this approach is not practical for the constraints of every design. An example PCB layout with the OPT4041 is shown in [Figure 8-3](#).

8.5.2 Layout Example

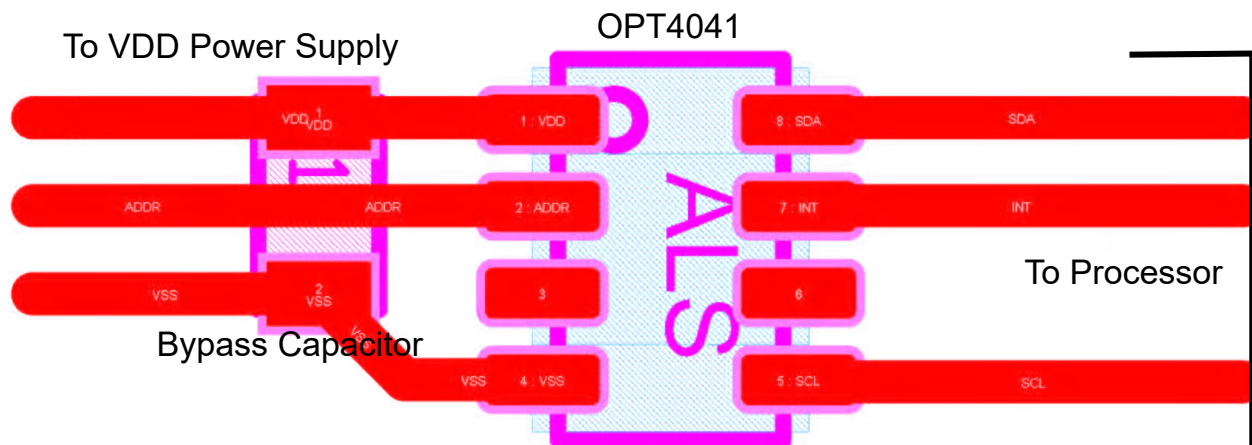

図 8-3. Layout Example for SOT-5X3 package

8.5.2.1 Soldering and Handling Recommendations

The OPT4041 has been qualified for three soldering reflow operations per JEDEC JSTD-020.

Note that excessive heat can discolor the device and affect optical performance.

See application report [SLUA271, QFN/SON PCB Attachment](#), for details on soldering thermal profile and other information. If the OPT4041 must be removed from a PCB, discard the device and do not reattach.

As with most optical devices, handle the device with special care to make sure that optical surfaces stay clean and free from damage. See [セクション 8.3](#) for more detailed recommendations. For best optical performance, solder flux and any other possible debris must be cleaned after soldering processes.

PACKAGING INFORMATION

Orderable part number	Status (1)	Material type (2)	Package Pins	Package qty Carrier	RoHS (3)	Lead finish/ Ball material (4)	MSL rating/ Peak reflow (5)	Op temp (°C)	Part marking (6)
OPT4041DTSR	Active	Production	SOT-5X3 (DTS) 8	250 SMALL T&R	Yes	NIPDAU	Level-2-260C-1 YEAR	-40 to 85	4041
OPT4041DTSR.A	Active	Production	SOT-5X3 (DTS) 8	250 SMALL T&R	Yes	NIPDAU	Level-2-260C-1 YEAR	-40 to 85	4041

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

4226132/G 01/2025

NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. Body dimensions do not include mold flash, protrusions or gate burrs. Mold flash, interlead flash, protrusions or gate burrs shall not exceed 0.171 per end or side.
4. The side flash along with the stub lead is allowed.
5. Any detached side flash from the stub lead is allowed unless it is touching the bottom side of the lead.

LAND PATTERN EXAMPLE
EXPOSED METAL SHOWN
SCALE: 30X

SOLDER MASK DETAILS

4226132/G 01/2025

NOTES: (continued)

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. Land pad design aligns to IPC-610, Bottom Termination Component (BTC) solder joint inspection criteria.

SOLDER PASTE EXAMPLE
 BASED ON 0.125 mm THICK STENCIL
 SCALE: 30X

4226132/G 01/2025

NOTES: (continued)

9. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
10. Board assembly site may have different recommendations for stencil design.
