

## THS4561 低消費電力、高電力範囲、60MHz、完全差動アンプ

## 1 特長

- ・ 帯域幅: 60MHz ( $G = 1V/V$ )
- ・ スルーレート: 230V/ $\mu$ s
- ・ ゲイン帯域幅積: 68MHz
- ・ 電圧ノイズ:
  - 1/f 電圧ノイズ・コーナー: 8Hz
  - 広帯域ノイズ ( $\geq 500\text{Hz}$ ):  $4\text{nV}/\sqrt{\text{Hz}}$
- ・ 入力オフセット:  $\pm 250\mu\text{V}$  以下
  - ドリフト:  $\pm 4\mu\text{V}/^\circ\text{C}$  以下
- ・ 電源動作範囲: 2.85V ~ 12.6V
- ・ 消費電流: 775 $\mu$ A
- ・ 負のレール入力 (NRI)
- ・ レール・ツー・レール出力 (RRO)
- ・ 非常に小さい高調波歪み:
  - HD2: 2V<sub>PP</sub>, 100kHz において -117dBc
  - HD3: 2V<sub>PP</sub>, 100kHz において -124dBc
- ・ 0.01% セトリング (2V ステップ): 90ns

## 2 アプリケーション

- ・ 16 ビットから 20 ビットまでの差動、SAR および  $\Delta\Sigma$  ドライバ
- ・ 差動アクティブ・フィルタ
- ・ 高出力スイングの PCM オーディオ DAC 出力
- ・ 超音波医療機器
- ・ バッテリ・テスト
- ・ 電力分析
- ・ THS4551 の低消費電力の代替品

## 3 概要

THS4561 完全差動アンプ (FDA) は、高精度アナログ / デジタル・コンバータ (ADC) に必要な、シングルエンド信

50kHz の 2 次 MFB フィルタを使用する 10V/V ゲインの PCM オーディオ DAC 出力

号源から差動出力への簡単なインターフェイスとして機能します。THS4561 は、わずか 775 $\mu$ A の静止電流でありながら、8Hz の非常に低い 1/f 電圧ノイズ・コーナーと -130dB の小さな全高調波歪み (THD) を実現するように設計されているため、アンプと ADC の組み合わせによる最高水準の信号対雑音比 (SNR) とスプリアス・フリー・ダイナミック・レンジ (SFDR) が必要とされる、電力の制約が厳しいデータ・アキュイジション (DAQ) システムに最適です。

THS4561 は、DC 結合、グランド中心のソース信号と、単一電源の差動入力 ADC とを接続するために必要な負レール入力機能を備えています。DC 誤差とドリフトが小さいため、新しい高速高分解能の逐次比較型 (SAR) およびデルタ・シグマ ( $\Delta\Sigma$ ) ADC の入力要件をサポートできます。2.85V ~ 12.6V の電源範囲に対応し、出力同相モード電圧を柔軟に設定でき、電源へのヘッドルームが小さくて済むため、幅広い ADC 入力および DAC 出力要件をサポートできます。

THS4561 デバイスは、 $-40^\circ\text{C}$  ~  $+125^\circ\text{C}$  で動作が規定されています。

## デバイス情報

部品番号	パッケージ <sup>(1)</sup>	本体サイズ (公称)
THS4561	VSSOP (8)	3.00mm × 3.00mm
	WQFN (10)	2.00mm × 2.00mm
	VQFN (16)	3.00mm × 3.00mm

(1) 利用可能なパッケージについては、データシートの末尾にあるパッケージ・オプションについての付録を参照してください。

高調波歪みと周波数との関係

## 4 Revision History

Changes from Revision C (December 2020) to Revision D (February 2021)	Page
• Changed the status of the RGT package from <i>preview</i> to <i>production</i> .....	4

Changes from Revision B (August 2020) to Revision C (December 2020)	Page
• 「特長」セクションのスルーレートを 315V/μs から 230V/μs に変更.....	1
• 「特長」セクションの「2 次 MFB フィルタを使用する 10V/V ゲインの PCM オーディオ DAC 出力」を更新.....	1
• THS4561 デバイスの WQFN (10) パッケージをリリース.....	1
• Changed the status of the RUN package from <i>preview</i> to <i>production</i> .....	4
• Separated slew rate specification into rising and falling specifications lines.....	5
• Changed the VOVM small-signal bandwidth test condition from 100 mV <sub>PP</sub> to 10 mV <sub>PP</sub> and the typical value from 23 MHz to 22 MHz .....	5
• Changed the VOVM large-signal bandwidth typical value from 10 MHz to 1.9 MHz .....	5
• Changed the maximum VOVM drift specification from 300 μV/°C .....	5
• Updated the Common-Mode Voltage, Small-Signal and Large-Signal Response (VOVM Pin Driven) figure in the <i>Typical Characteristics: (V<sub>S+</sub>) - (V<sub>S-</sub>) = 3-V to 12-V Supply Range</i> section .....	16
• Updated the MFB Filter Driving an ADC Application figure in the <i>Typical Application</i> section .....	33

Changes from Revision A (December 2019) to Revision B (August 2020)	Page
• 文書全体にわたって表、図、相互参照の採番方法を更新.....	1
• Added the VQFN-10 and VQFN-16 Package Outlines.....	37

Changes from Revision * (August 2017) to Revision A (December 2019)	Page
• デバイスのステータスを事前情報から量産データに変更.....	1

## 6 Pin Configuration and Functions

图 6-1. DGK Package 8-Pin VSSOP Top View

图 6-2. RUN Package 10-Pin WQFN Top View

图 6-3. RGT Package 16-Pin VQFN With Exposed Thermal Pad Top View

表 6-1. Pin Functions

PIN				TYPE <sup>(2)</sup>	DESCRIPTION
NAME	DGK	RUN	RGT <sup>(1)</sup>		
FB-	—	—	1	O	Inverting (negative) output feedback
FB+	—	—	4	O	Noninverting (positive) output feedback
IN-	1	6	3	I	Inverting (negative) amplifier input
IN+	8	4	2	I	Noninverting (positive) amplifier input
NC	—	2, 8	—	—	No internal connection
OUT-	5	1	11	O	Inverting (negative) amplifier output
OUT+	4	9	10	O	Noninverting (positive) amplifier output
PD	7	3	12	I	Power down. $\overline{\text{PD}}$ = logic low = power off mode; $\overline{\text{PD}}$ = logic high = normal operation.
VOCM	2	7	9	I	Common-mode voltage input
VS-	6	5	13, 14, 15, 16	P	Negative power-supply input
VS+	3	10	5, 6, 7, 8	P	Positive power-supply input

(1) Solder the exposed RGT package thermal pad to a heat-spreading power or ground plane. This pad is electrically isolated from the die, but must be connected to a power or ground plane and not floated.

(2) I = input, O = output, P = power.

## 7 Specifications

### 7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)<sup>(1)</sup>

		MIN	MAX	UNIT
Voltage	Total supply voltage, $V_S = (V_{S+} - V_{S-})$		13.5	V
	Supply turn-on/off $dV/dT$ <sup>(2)</sup>		$\pm 0.35$	V/ $\mu$ s
	Input, output, power down and common-mode pin voltage range	$(V_{S-}) - 0.5$	$(V_{S+}) + 0.5$	V
	Differential input voltage		$\pm 1$	V
Current	Continuous input current		$\pm 10$	mA
	Continuous output current <sup>(3)</sup>		$\pm 20$	mA
Temperature	Junction temperature, $T_J$		150	°C
	Operating free-air temperature, $T_A$	-40	125	°C
	Storage temperature, $T_{slg}$	-65	150	°C

- (1) Stresses beyond those listed under [Absolute Maximum Ratings](#) may cause permanent damage to the device. These stress-only ratings do not imply functional operation of the device at these or any other conditions beyond those indicated under [Recommended Operating Conditions](#). Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) Staying below this specification ensures that the edge-triggered ESD absorption devices across the supply pins remains off.
- (3) Long-term continuous output current for electromigration limits.

### 7.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins <sup>(1)</sup>	$\pm 3500$	V
		Charged device model (CDM), per JEDEC specification JESD22-C101, all pins <sup>(2)</sup>	$\pm 1250$	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
$V_S$	Total supply voltage	2.85		12.6	V
$T_A$	Operating free-air temperature	-40	25	125	°C

### 7.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		THS4561			UNIT
		DGK (VSSOP)	RUN (WQFN)	RGT (VQFN)	
		8 PINS	10 PINS	16 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	183.1	134.6	55.9	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	70.3	83.6	64.5	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	104.9	67.7	30.5	°C/W
$\Psi_{JT}$	Junction-to-top characterization parameter	10.8	7.2	3.5	°C/W
$\Psi_{JB}$	Junction-to-board characterization parameter	103.2	67.5	30.5	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	N/A	N/A	15.6	°C/W

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

## 7.5 Electrical Characteristics: $V_{S+} - V_{S-} = 5\text{ V to }12\text{ V}$

at  $T_A \approx 25^\circ\text{C}$ ,  $\text{VOCM}^{(1)}$  = midsupply, differential output ( $V_O$ ) =  $V_{\text{OUT}+} - V_{\text{OUT}-} = 2\text{ V}_{\text{PP}}$ ,  $R_F = 1.5\text{ k}\Omega$ ,  $R_L = 1\text{ k}\Omega$ ,  $50\text{-}\Omega$  input match, differential closed-loop gain ( $G$ ) =  $1\text{ V/V}$ , single-ended input (SE-in), differential output (diff-out), and input and output referenced to midsupply for AC-coupled tests (unless otherwise noted)

PARAMETER		TEST CONDITIONS		MIN	TYP	MAX	UNIT
AC PERFORMANCE							
SSBW	Small-signal bandwidth	$V_S = 5\text{ V}$ , $V_O = 200\text{ mV}_{PP}$ , 2-dB peaking		60		MHz	
							$V_S = 5\text{ V}$ , $V_O = 200\text{ mV}_{PP}$
			$G = 5\text{ V/V}$	12.5			
					$G = 10\text{ V/V}$		6.3
GBWP	Gain-bandwidth product	$V_O = 200\text{ mV}_{PP}$ , $G = 20\text{ V/V}$ , $R_F = 10\text{ k}\Omega$		68		MHz	
LSBW	Large-signal bandwidth	$V_O = 4\text{ V}_{PP}$		20		MHz	
	Bandwidth for 0.1-dB flatness			5		MHz	
SR	Slew rate (20% – 80%)	$V_S = 5\text{ V}$ , $V_O = 2\text{-V}$ step	Rising	325		V/ $\mu\text{s}$	
			Falling	230		V/ $\mu\text{s}$	
	Overshoot and undershoot	$V_O = 2\text{-V}$ step, input $t_r = 10\text{ ns}$	$V_S = 12\text{ V}$	5%			
			$V_S = 5\text{ V}$	11%			
	0.1% settling time	$V_O = 2\text{-V}$ step, input $t_r = 10\text{ ns}$		40		ns	
	0.01% settling time	$V_O = 2\text{-V}$ step, input $t_r = 10\text{ ns}$		90		ns	
	Rise and fall time (10% – 90%)	$V_O = 100\text{-mV}$ step, input $t_r = 2\text{ ns}$		5.7		ns	
HD2	Second-order harmonic distortion	$V_S = 5\text{ V}$ , $f = 100\text{ kHz}$	$V_o = 2\text{ V}_{PP}$	–117		dBc	
			$V_o = 8\text{ V}_{PP}$	–110			
HD3	Third-order harmonic distortion	$V_S = 5\text{ V}$ , $f = 100\text{ kHz}$	$V_o = 2\text{ V}_{PP}$	–124			
			$V_o = 8\text{ V}_{PP}$	–106			
$e_n$	Input differential voltage noise	$f \geq 500\text{ Hz}$		4		nV/ $\sqrt{\text{Hz}}$	
		1/f corner		8		Hz	
$i_n$	Input current noise, each input	$f \geq 50\text{ kHz}$		0.35		pA/ $\sqrt{\text{Hz}}$	
	Overdrive recovery time	$V_S = 5\text{ V}$ , $G = 2\text{ V/V}$ , 2x output overdrive, dc-coupled		210		ns	
$Z_{OUT}$	Closed-loop output impedance	$f = 100\text{ kHz}$ (differential)		0.06		$\Omega$	
DC PERFORMANCE							
$A_{OL}$	Open-loop voltage gain	$V_o = \pm 2\text{ V}$		104	115		dB
$V_{OS}$	Input offset voltage	$T_A = 25^\circ\text{C}$		–250	$\pm 50$	250	$\mu\text{V}$
	Input offset voltage drift	$T_A = 0^\circ\text{C}$ to $85^\circ\text{C}$ , $T_A = -40^\circ\text{C}$ to $125^\circ\text{C}$		–4	$\pm 0.5$	4	$\mu\text{V}/^\circ\text{C}$
$I_{B+}$ , $I_{B-}$	Input bias current <sup>(3)</sup>	$T_A = 25^\circ\text{C}$			370	600	nA
	Input bias current drift	$T_A = -40^\circ\text{C}$ to $125^\circ\text{C}$			4.1	8	nA/ $^\circ\text{C}$
$I_{OS}$	Input offset current <sup>(4)</sup>	$T_A = 25^\circ\text{C}$		–20	$\pm 2$	20	nA
	Input offset current drift	$T_A = -40^\circ\text{C}$ to $125^\circ\text{C}$		–200	$\pm 40$	200	pA/ $^\circ\text{C}$
INPUT							
$V_{ICML}$	Common-mode input low	$T_A = -40^\circ\text{C}$ to $125^\circ\text{C}$ , 3-dB $A_{OL}$ degradation from midsupply $\text{VOCM } A_{OL}$		$V_{S-} - 0.1$		$V_{S-}$	V
$V_{ICMH}$	Common-mode input high	3-dB $A_{OL}$ degradation from midsupply $\text{VOCM } A_{OL}$	$T_A = 25^\circ\text{C}$	$V_{S+} - 1.2$	$V_{S+} - 1.1$	V	
			$T_A = -40^\circ\text{C}$ to $125^\circ\text{C}$	$V_{S+} - 1.35$	$V_{S+} - 1.2$		
CMRR	Common-mode rejection ratio	Midsupply inputs		95	110	dB	
		Midsupply inputs, $T_A = -40^\circ\text{C}$ to $125^\circ\text{C}$		108			
	Differential input impedance	Inputs at midsupply		150    2.4		k $\Omega$    pF	

## 7.5 Electrical Characteristics: $V_{S+} - V_{S-} = 5\text{ V to }12\text{ V}$ (continued)

at  $T_A \approx 25^\circ\text{C}$ ,  $\text{VOCM}^{(1)} = \text{midsupply}$ , differential output ( $V_O$ ) =  $V_{\text{OUT}+} - V_{\text{OUT}-} = 2 V_{\text{PP}}$ ,  $R_F = 1.5\text{ k}\Omega$ ,  $R_L = 1\text{ k}\Omega$ ,  $50\text{-}\Omega$  input match, differential closed-loop gain ( $G$ ) =  $1\text{ V/V}$ , single-ended input (SE-in), differential output (diff-out), and input and output referenced to midsupply for AC-coupled tests (unless otherwise noted)

## 8 Parameter Measurement Information

### 8.1 Example Characterization Circuits

The THS4561 offers the advantages of a fully differential amplifier (FDA) design with the trimmed input offset voltage and low drift of a precision op amp. The FDA is a flexible device where the main aim is to provide a purely differential output signal centered on a user-configurable common-mode voltage usually matched to the input common-mode voltage required by an analog-to-digital converter (ADC) following the FDA stage. The primary options revolve around the choices of single-ended or differential inputs, AC-coupled or DC-coupled signal paths, gain targets, and resistor value selections. The characterization circuits described in this section focus on single-ended input to differential output designs as the more challenging application requirement. Differential sources are supported and are simple to implement and analyze.

The characterization circuits are typically operated with a single-ended, matched, 50-Ω, input termination to a differential output at the FDA output pins because most lab equipment is single-ended. The FDA differential output is then translated back to single-ended through a variety of baluns (or transformers) depending on the test and frequency range. DC-coupled step response testing uses two 50-Ω scope inputs with trace math to measure the differential output. Single-supply operation is most common in end equipment designs. However, using split balanced supplies allows simple ground referenced testing without adding further blocking capacitors in the signal path beyond those capacitors already within the test equipment. The starting point for any single-ended input to differential output measurements (such as any of the frequency response curves) is shown in [Figure 8-1](#).

**Figure 8-1. Single-Ended Source to a Differential Gain of a 1-V/V Test Circuit**

Most characterization plots fix the  $R_F$  ( $R_{F1} = R_{F2}$ ) value at 1.5 kΩ, as shown in [Figure 8-1](#). This element value is flexible in application, but 1.5 kΩ provides a good compromise for the parasitic issues linked to this value, specifically:

- Added output loading: The FDA functions similarly to an inverting op amp design with feedback resistors appearing as an added load across the outputs (the approximate total differential load in [Figure 8-1](#) is  $1.5 \text{ k}\Omega \parallel 1 \text{ k}\Omega = 857 \text{ }\Omega$ ). The 1.5-kΩ value reduces the power dissipated in the feedback networks.
- Noise contributions resulting from resistor values. These contributions are both the  $4kTR_F$  terms and the current noise times the  $R_F$  term referred to the output (see [Section 10.1.3](#)).
- Parasitic feedback pole at the input summing nodes. This pole is created by the feedback resistor ( $R_F$ ) value and the 2.4-pF differential input capacitance (as well as any board layout parasitic) and introduces a zero in the noise gain, which decreases the phase margin in most situations. This effect must be managed for best frequency response flatness or step response overshoot.

The frequency domain characterization curves start with the circuit and component selections of [Figure 8-1](#). Some of the features in this test circuit include:

- The elements on the non-signal input side match the signal input resistors. This feature closely matches the divider networks on each side of the FDA. The three resistors ( $R_{G2}$ ,  $R_{T2}$ , and  $R_{S1}$ ) on the non-signal input side can be replaced by a single resistor to ground using a standard value of 1.5 k $\Omega$  with some loss in gain balancing between the two sides.
- Translating from a 1-k $\Omega$  differential load to a 50- $\Omega$  environment introduces considerable insertion loss in the measurements (–31.8 dB in [Figure 8-1](#)). The measurement path insertion loss normalizes when reporting the frequency response curves to show the gain response to the FDA output pins.
- In the pass band for the output balun, the 50- $\Omega$  load of the network analyzer reflects in parallel with the 52.3- $\Omega$  shunt termination,  $R_M$ . These elements combine to show a differential 1-k $\Omega$  load at the output pins of the THS4561. The source impedance presented to the balun is a differential 50- $\Omega$  source. [Figure 8-2](#) and [Figure 8-3](#) show the TINA-TI™ model (available as a [TINA-TI™ simulation file](#)) and resulting response flatness for this relatively low-frequency balun providing 0.1-dB flatness through 100 MHz.

**Figure 8-2. Output Measurement Balun Simulation Circuit in TINA-TI™**

**Figure 8-3. Output Measurement Balun Flatness Test**

Starting from the test circuit of [Figure 8-1](#), various elements are modified to show the effect of these elements over a range of design targets, specifically:

- The gain setting is changed by adjusting the two  $R_T$  and the  $R_G$  resistors to provide a 50- $\Omega$  input match and setting the feedback resistors to 1.5 k $\Omega$ .
- Resistive and capacitive output load testing. Changing to lower resistive loads is accomplished by adding parallel resistors across the output pins in [Figure 8-1](#). Changing to capacitive loads adds series output resistors to a differential capacitance before the 1-k $\Omega$  sense path of [Figure 8-1](#).
- Power-supply settings. Most often, balanced bipolar supplies are used; a 12-V tests use  $\pm 6$ -V supplies, 5-V tests use  $\pm 2.5$ -V supplies, and 3-V tests use  $\pm 1.5$ -V supplies with the VO<sub>CM</sub> input control grounded.
- The disable control pin ( $\overline{\text{PD}}$ ) is tied to the positive supply ( $V_{S+}$ ) for any active channel test.

## 8.2 Output Interface Circuit for DC-Coupled Differential Testing

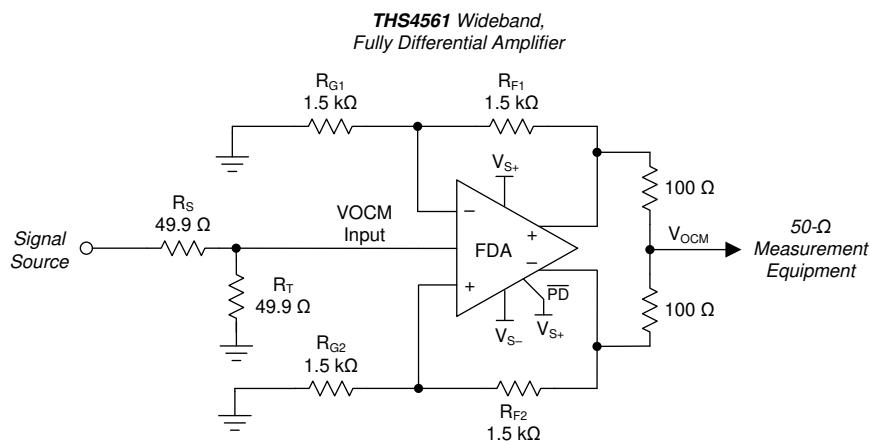

The pulse response plots are measured using the output circuit of [Figure 8-4](#). The two sides of this circuit present a 500- $\Omega$  load to ground (for a differential 1-k $\Omega$  load) with a 50- $\Omega$  source to the two scope inputs. Trace math function of the scope combines the two sides to generate the step response plots of [Figure 7-13](#), [Figure 7-27](#), and [Figure 7-44](#). Use balanced bipolar supplies for this test so that the THS4561 outputs deliver a ground-centered differential swing. This setup produces no DC load currents using the circuit of [Figure 8-4](#).

**Figure 8-4. Output Interface for DC-Coupled Differential Outputs**

## 8.3 Output Common-Mode Measurements

The circuit of [Figure 8-5](#) is a typical setup for common-mode measurements.

**Figure 8-5. Output Common-Mode Measurements**

In [Figure 8-5](#), the differential path is terminated back to ground with the two 1.5-k $\Omega$  input resistors and the VO<sub>CM</sub> control input is driven from a 50- $\Omega$  matched source for the frequency response and step response curves of [Figure 7-47](#), [Figure 7-49](#), and [Figure 7-50](#). The outputs are summed to a center point (to obtain the average, or common-mode output, V<sub>OCM</sub>) through two 100- $\Omega$  resistors. These 100- $\Omega$  resistors form an equivalent 50- $\Omega$  source to the common-mode output for measurements. [Figure 7-48](#) illustrates the common-mode output noise measurements with

a ground on the VOCM input pin or with the VOCM input pin floating. The higher noise in [Figure 7-48](#) for a floated input can be reduced by including a capacitor to ground at the VOCM control input pin.

## 8.4 Differential Amplifier Noise Measurements

To extract the input-referred noise terms from the total output noise, a measurement of the differential output noise is required under two external conditions to emphasize the different noise terms. A high-gain, low resistor value condition is used to emphasize the differential input voltage noise and a higher  $R_F$  at low gains is used to emphasize the two input current noise terms. The differential output noise must be converted to single-ended with added gain before being measured by a spectrum analyzer. At low frequencies, a zero 1/f noise, high-gain, differential to single-ended instrumentation amplifier (such as the [INA188](#)) is used. At higher frequencies, a differential to single-ended balun is used to drive into a high-gain, low-noise, op amp (such as the [LMH6629](#)). In this case, the THS4561 outputs drive 25- $\Omega$  resistors into a 1:1 balun where the balun output is terminated single-endedly at the LMH6629 input with 50  $\Omega$ . This termination provides a modest 6-dB insertion loss for the THS4561 differential output noise that is then followed by a 40-dB gain setting in the very wideband [LMH6629](#).

## 8.5 Balanced Split-Supply Versus Single-Supply Characterization

Although most end applications use a single-supply implementation, most characterizations are done on a bipolar balanced supply. Using a bipolar balanced supply keeps the I/O common-mode inputs near midsupply and provides the most output swing with no DC bias currents for level shifting. These characterizations include the frequency response, harmonic distortion, and noise plots. The time domain plots are in some cases done through single-supply characterization to obtain the correct movement of the input common-mode voltage.

## 8.6 Simulated Characterization Curves

In some cases, a characteristic curve can only be generated through simulation. A good example of this scenario is the output balance plot of [Figure 7-51](#). This plot shows the best-case output balance (output differential signal versus output common-mode signal) using exact matching of the external resistors in simulation using a single-ended input to differential output configuration. The actual output balance is set by resistor mismatch at low frequencies but intersects and follows the high-frequency portion of [Figure 7-51](#) at higher frequencies.

The remaining simulated plots include:

- $A_{OL}$  gain and phase; see [Figure 7-41](#).
- CMRR and PSRR vs frequency; see [Figure 7-52](#).

## 8.7 Terminology and Application Assumptions

There are common terms that are unique to this device. This section identifies and explains these terms.

- Fully differential amplifier (FDA). This term is restricted to devices offering what is similar to a differential inverting op amp design element that requires an input resistor (not a high-impedance input) and includes a second internal control loop that sets the output average voltage ( $V_{OCM}$ ) to a default or set point. This second common-mode control loop interacts with the differential loop in certain configurations.
- The desired output signal at the two output pins is a differential signal that swings symmetrically around a common-mode voltage,  $V_{OCM}$ , which is the average voltage of the two outputs.
- Single-ended to differential. Generally the output is always used differentially in an FDA; however, the source signal can be either a single-ended or a differential source. For an FDA operating in single-ended to differential, the input is applied only to one of the two inputs via input resistors.
- The common-mode control loop has limited bandwidth from the input VOCM pin to the common-mode output voltage. The internal loop bandwidth beyond the input VOCM buffer is a much wider bandwidth than the reported VOCM bandwidth, but is not directly discernable. A very wide bandwidth in the internal VOCM loop is required to perform an effective and low-distortion single-ended to differential conversion.

Several features in the application of the THS4561 are not explicitly stated, but are necessary for correct operation. These features are:

- Although often not stated, the disable pin ( $\overline{PD}$ ) is tied to the positive supply when an enabled channel is desired.
- Virtually all ac characterization equipment expects a 50- $\Omega$  termination from the 50- $\Omega$  source and a 50- $\Omega$ , single-ended source impedance from the device outputs to the 50- $\Omega$  sensing termination. This condition is achieved in all characterizations (often with some insertion loss) but is not necessary for most applications. Matching impedance is most often required when transmitting over longer distances. Tight layouts from a source, through the THS4561, and to an ADC input do not require doubly-terminated lines or filter designs. The only exception is if the source requires a defined termination impedance for correct operation (for example, mixer outputs).
- The amplifier signal path is flexible for use as single-supply or split-supply operation. Most applications are intended to be single supply, but any split-supply design can be used as long as the total supply voltage across the THS4561 is less than 12.6 V and the required input, output, and common-mode pin headrooms to each supply are taken into account. When left open, the VOCM pin defaults to near midsupply for any combination of split or single supplies used.
- External element values are normally assumed to be accurate and matched. In an FDA, this assumption translates to equal feedback resistor values and a matched impedance from each input summing junction to either a signal source or a DC bias reference on each side of the inputs. Unbalancing these values introduces non-idealities in the signal path. For the signal path, imbalanced resistor ratios on the two sides creates a common-mode to differential conversion. Furthermore, mismatched  $R_F$  values and feedback ratios create additional differential output error terms from any common-mode DC or AC signal or noise terms. Using standard 1% resistor values is a typical approach and generally leads to some nominal feedback ratio mismatch. Modestly mismatched resistors or ratios do not by themselves degrade harmonic distortion. Where there is a meaningful common-mode noise or distortion in the input signal, that gets converted to differential via an element or ratio mismatch. For the best DC precision, use 0.1% accuracy resistors that are readily available in E96 values.

## 9 Detailed Description

### 9.1 Overview

The THS4561 is a fully differential amplifier featuring an extremely flexible supply voltage range of 2.85 V to 12.6 V, which makes this device an excellent choice for driving differential ADCs and buffering DAC outputs. This device features a low-power mode with a unique active-pullup resistor (not a conventional pullup resistor) that improves EMI reliability of the shutdown pin when left floating. This pin draws very little bias current when enabled, but increases the bias current as it nears the threshold point of shutdown. The increased current prevents the pin from unintentionally turning the device off in the presence of EMI on the disable pin. Similar to other fully differential amplifiers, the THS4561 also includes an output common-mode control pin that can be used to independently set the output common mode to match that of an ADC or other load circuit.

### 9.2 Functional Block Diagram

## 9.3 Feature Description

In addition to the core differential I/O voltage feedback gain block, there are two 6-k $\Omega$  resistors internally across the outputs to sense the average voltage at the outputs. These resistors feed the average voltage back into a  $V_{CM}$  error amplifier where the voltage is compared to either a default voltage divider across the supplies or an externally set VOCM target voltage. When the amplifier is disabled, the default midsupply bias string is disabled to save power.

To achieve the very-low noise at the low power provided by the THS4561, the input stage transistors are relatively large, thus resulting in a higher differential input capacitance (2.4 pF in [セクション 9.2](#)). When using the 16-pin WQFN package and the internal feedback traces to the input side of the package, include the nominal trace impedance of 8.5  $\Omega$  in the design. These elements are not included in the TINA-TI™ model and must be added externally to a design intending to use the RGT package.

## 9.4 Device Functional Modes

The wideband FDA requires external resistors for correct signal-path operation. When configured for the desired input impedance and gain setting with these external resistors, the amplifier can be either on with the  $\overline{PD}$  pin asserted to a voltage greater than  $(V_{S+}) - 0.5$  V, or turned off by asserting  $\overline{PD}$  low (1.8 V below the positive supply). Disabling the amplifier shuts off the quiescent current and stops correct amplifier operation. The signal path is still present for the source signal through the external resistors, which provides poor signal isolation from the input to output in power-down mode.

Internal protection diodes remain present across the input pins in both operating and shutdown mode. Large input signals during disable can turn on the input differential protection diodes, thus producing a load current in the supply even in power-down.

The VOCM control pin sets the output average voltage. The VOCM defaults to an internal midsupply value if left open. Driving this high-impedance input with a voltage reference within the valid range sets a target for the internal  $V_{CM}$  error amplifier. If floated to obtain a default midsupply reference for VOCM, an external decoupling capacitor is recommended to be added on the VOCM pin to reduce the otherwise high output noise for the internal high-impedance bias (see [図 7-48](#)).

### 9.4.1 Power-Down Mode

The power down ( $\overline{PD}$ ) pin must be asserted to the desired voltage for proper power-down mode operation. A physical internal pullup resistor is not provided on the  $\overline{PD}$  pin so that if the pin is floated, the device defaults to an ON state. Tie the  $\overline{PD}$  pin to the positive supply voltage for applications that simply require the device to power on when the supplies are present. For single-supply operation, a minimum of 0.5 V within the positive supply is required for operation.

The disable operation is referenced from the positive supply. For an OFF state condition, the disable control pin must be 1.8 V below the positive supply. The THS4561 has a unique power-down circuit that requires overcoming the specified peak  $\overline{PD}$  pulldown current when the  $\overline{PD}$  voltage is pulled low. When this current threshold is overcome, the  $\overline{PD}$  current drops to a very small value. The benefit of the circuit is that the device stays disabled without having to use an active pullup resistor that wastes crucial power to keep the amplifier disabled in power-sensitive applications.

### 9.4.2 Single-Ended Source to Differential Output Mode

One of the most useful features supported by the FDA device is an easy conversion from a single-ended input to a differential output centered on a user-controlled, common-mode level. Although the output side is relatively straightforward, the device input pins move in a common-mode manner with the input signal. The common-mode voltage at the input pins, which moves with the input signal, increases the apparent input impedance to be greater than the  $R_G$  value. The input active impedance issue applies to both AC-coupled and DC-coupled designs, and requires somewhat more complex solutions for the resistors to account for this active impedance, as discussed in [セクション 10.1.2](#).

#### 9.4.2.1 AC-Coupled Signal Path Considerations for Single-Ended Input to Differential Output Conversions

When the signal path can be AC-coupled, the DC biasing for the THS4561 becomes a relatively simple task. In all designs, start by defining the output common-mode voltage. The AC-coupling requirement can be separated for the input and output sides of an FDA design. The input can be AC-coupled and the output DC-coupled, or the output can be AC-coupled and the input DC-coupled, or both can be AC-coupled. One situation where the output can be DC-coupled (for an AC-coupled input), is when driving directly into an ADC where the V<sub>OCM</sub> control voltage uses the ADC common-mode reference to directly bias the FDA output common-mode voltage to the required ADC input common-mode voltage. In any case, the design starts by setting the desired V<sub>OCM</sub>. When an AC-coupled path follows the output pins, the best linearity is achieved by operating V<sub>OCM</sub> at midsupply, which can be easily delivered by floating the V<sub>OCM</sub> pin. The V<sub>OCM</sub> voltage must be within the linear range for the common-mode loop, as specified in the headroom specifications. If the output path is also AC-coupled, simply letting the V<sub>OCM</sub> control pin float is usually preferred in order to obtain a midsupply default V<sub>OCM</sub> bias with minimal elements. To limit noise, place a 0.1-μF decoupling capacitor on the V<sub>OCM</sub> control pin to ground.

After V<sub>OCM</sub> is defined, check the target output voltage swing to make certain that the V<sub>OCM</sub> plus the positive and negative output swing on each side does not clip into the supplies. If the desired peak-to-peak output differential swing is defined as V<sub>OPP</sub>, divide by 4 to obtain the ±V<sub>P</sub> (peak voltage) swing around V<sub>OCM</sub> at each of the two output pins (each pin operates 180° out of phase with the other). Check that V<sub>OCM</sub> ±V<sub>P</sub> does not exceed the absolute supply rails for the rail-to-rail output (RRO) device. Common-mode current does not flow from the common-mode output voltage set by the V<sub>OCM</sub> pin towards the device input pins side, because both the source and balancing resistor on the non-signal input side are DC blocked. The AC-coupled input path sets the input pin common-mode voltage equal to the output common-mode voltage. If the V<sub>OCM</sub> voltage is within the headroom requirement, then the input pins are also in range for the AC-coupled input configuration. This headroom requirement functions similarly for when the V<sub>OCM</sub> voltage approaches the negative supply.

The input pin voltages move in a common-mode manner with the input signal. Confirm that the V<sub>OCM</sub> voltage plus the input V<sub>PP</sub> common-mode swing also stays in the V<sub>ICM</sub> specification range for the input pins.

#### 9.4.2.2 DC-Coupled Input Signal Path Considerations for Single-Ended to Differential Conversions

The output considerations remain the same as for the AC-coupled design. Again, the input can be DC-coupled when the output is ac coupled. A DC-coupled input with an AC-coupled output can have some advantages to move the input V<sub>ICM</sub> down by adjusting the V<sub>OCM</sub> down if the source is ground referenced. When the source is DC-coupled into the THS4561 (see [Figure 10-3](#)), both sides of the input circuit must be DC-coupled to retain differential balance. Normally, the non-signal input side has an R<sub>G</sub> element biased to whatever the source midrange is expected to be, provided that this midscale reference gives a balanced differential swing around V<sub>OCM</sub> at the outputs. Often, R<sub>G2</sub> is simply grounded for DC-coupled, bipolar-input applications. This configuration provides a balanced differential output if the source swings around ground. If the source swings from ground to some positive voltage, grounding R<sub>G2</sub> gives a unipolar output differential swing from both outputs at V<sub>OCM</sub> (when the input is at ground) to one polarity of the swing. Biasing R<sub>G2</sub> to an expected midpoint for the input signal creates a differential output swing around V<sub>OCM</sub>.

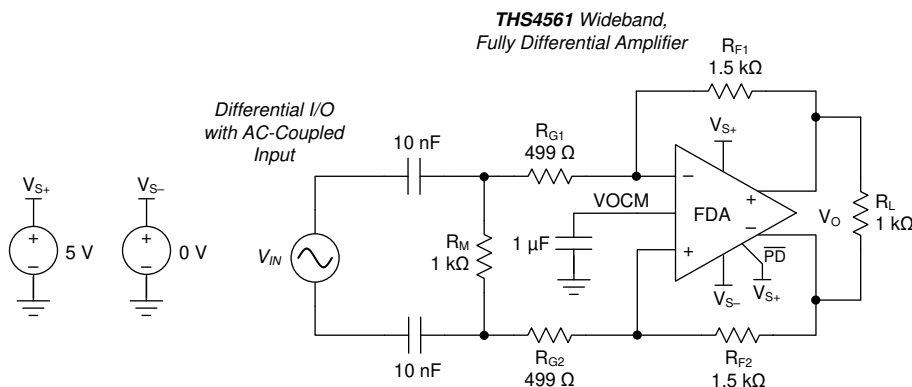

One significant consideration for a DC-coupled input is that V<sub>OCM</sub> sets up a common-mode bias current from the output back through R<sub>F</sub> and R<sub>G</sub> to the source on both sides of the feedback. Without input balancing networks, the source must sink or source this dc current. After the input signal range and biasing on the other R<sub>G</sub> element is set, check that the voltage divider from V<sub>OCM</sub> to V<sub>IN</sub> through R<sub>F</sub> and R<sub>G</sub> (and possibly R<sub>S</sub>) establishes an input V<sub>ICM</sub> at the device input pins that is within the specification range. If the average source is at ground, the negative rail input stage for the THS4561 is in range for applications using a single positive supply and a positive output V<sub>OCM</sub> setting because this dc common-mode current lifts the average FDA input summing junctions above ground to a positive voltage (the average of the V<sub>+</sub> and V<sub>–</sub> input pin voltages on the FDA). TINA-TI™ simulations of the intended circuit offer a good check for input and output pin voltage swings.

### 9.4.3 Differential Input to a Differential Output Mode

In many ways, this method is a much simpler way to operate the FDA from a design equations perspective. Again, assuming that the two sides of the circuit are balanced with equal  $R_F$  and  $R_G$  elements, the differential input impedance is now just the sum of the two  $R_G$  elements to a differential inverting summing junction. In these designs, the input common-mode voltage at the summing junctions does not move with the signal but must be dc biased in the design range for the input pins and must take into account the voltage headroom required to each supply. Slightly different considerations apply to AC-coupled or DC-coupled differential input to differential output designs, as described in the following sections.

#### 9.4.3.1 AC-Coupled, Differential-Input to Differential-Output Design Issues

The most common way to use the THS4561 with an AC-coupled differential source is to simply couple the input into the  $R_G$  resistors through the blocking capacitors. Figure 9-1 shows a typical blocking capacitor approach to a differential input. An optional input differential termination resistor ( $R_M$ ) is included in this design. The  $R_M$  element allows the input  $R_G$  resistors to be scaled up and still delivers lower differential input impedance to the source. In this example, the  $R_G$  elements sum to show a 1-k $\Omega$  differential impedance and the  $R_M$  element combines in parallel to provide a net 500- $\Omega$  ac differential impedance to the source. Again, the design ideally proceeds by selecting the  $R_F$  element values, then the  $R_G$  to set the differential gain, and then an  $R_M$  element (if needed) to achieve a target input impedance. Alternatively, the  $R_M$  element can be eliminated, with the  $2 \times R_G$  elements set to the desired input impedance and  $R_F$  set to obtain the differential gain (equal to  $R_F / R_G$ ).

**Figure 9-1. Example AC-Coupled Differential Input Design**

The DC biasing for an AC-coupled differential input design is very simple. The output  $V_{OCM}$  is set by the  $V_{OCM}$  input control voltage and, because there is no DC current path for the output common-mode voltage (as long as  $R_M$  is only differential and not split and connected to ground for instance), the  $V_{OCM}$  DC bias also sets the common-mode operating points for the input pins. For a purely differential input, the voltages on the input pins remain fixed at the output  $V_{OCM}$  setting and do not move with the input signal (unlike the single-ended input configurations where the input pin common-mode voltages do move with the input signal).

## 10 Application and Implementation

### Note

以下のアプリケーション情報は、TI の製品仕様に含まれるものではなく、TI ではその正確性または完全性を保証いたしません。個々の目的に対する製品の適合性については、お客様の責任で判断していただくことになります。また、お客様は自身の設計実装を検証しテストすることで、システムの機能を確認する必要があります。

### 10.1 Application Information

Most applications for the THS4561 strive to deliver the best dynamic range in a design that delivers the desired signal processing along with adequate phase margin for the amplifier itself. The following sections detail some of the design issues with analysis and guidelines for improved performance.

#### 10.1.1 Differential Open-Loop Gain and Output Impedance

The most important elements to the closed-loop performance are the open-loop gain and open-loop output impedance. [Figure 10-1](#) shows the simulated differential open-loop gain and phase from the differential inputs to the differential outputs with no load and with a 100-Ω load. Operating with no load removes any effect introduced by the open-loop output impedance to a finite load. [Figure 10-2](#) shows the simulated differential open-loop output impedance.

**Figure 10-1. No-Load and 100-Ω Loaded  $A_{OL}$  Gain and Phase**

**Figure 10-2. Differential Open-Loop Output Impedance**

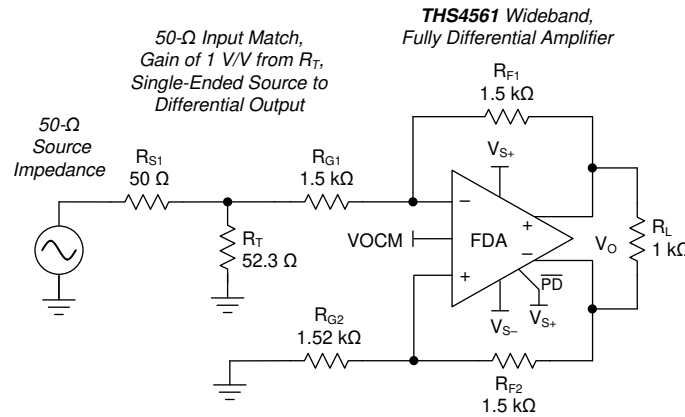

This open-loop output impedance combines with the load to shift the apparent open-loop gain and phase to the output pins when the load changes. The rail-to-rail output stage shows a very high impedance at low frequencies that reduces with frequency to a lower midrange value and then peaks again at higher frequencies. The maximum value at low frequencies is set by the common-mode sensing resistors to be a 6-kΩ dc value (see [Section 9.2](#).) This high impedance at a low frequency is significantly reduced in closed-loop operation by the loop gain, as shown in the closed-loop output impedance of [Figure 7-43](#). [Figure 10-1](#) compares the no load  $A_{OL}$  gain to the  $A_{OL}$  gain driving a 100-Ω load that shows the effect of the output impedance. The heavier loads pull the  $A_{OL}$  gain down faster to lower crossovers with more phase shift at the lower frequencies.

The much faster phase rolloff for the 100-Ω differential load explains the greater peaked response illustrated in [Figure 7-4](#) and [Figure 7-18](#) when the load decreases. This same effect happens for the RC loads common with converter interface designs. Use the TINA-TI™ model to verify loop phase margin in any design.

### 10.1.2 Setting Resistor Values Versus Gain

The THS4561 offers considerable flexibility in the configuration and selection of resistor values. The design starts with the selection of the feedback resistor value. The 1.5-kΩ feedback resistor value used for the characterization curves is a good compromise between power, noise, and phase margin considerations. With the feedback resistor values selected (and set equal on each side) the input resistors are set to obtain the desired gain with input impedance also set with these input resistors. Differential I/O designs provide an input impedance that is the sum of the two input resistors. Single-ended input to differential output designs present a more complicated input impedance. Most characteristic curves implement the single-ended to differential design as the more challenging requirement over differential-to-differential I/O.

For single-ended, matched, input impedance designs, 表 10-1 illustrates the suggested standard resistors set to approximately a 1.5-kΩ feedback. This table assumes a 50-Ω source and a 50-Ω input match and uses a single resistor on the non-signal input side for gain matching. Better matching is possible using the same three resistors on the non-signal input side as on the input side. 图 10-3 shows the element values and naming convention for the gain of 1-V/V configuration where the gain is defined from the matched input at  $R_T$  to the differential output.

**图 10-3. Single-Ended to Differential Gain of 1 V/V with Input Matching Using Standard Resistor Values**

Starting from a target feedback resistor value, the desired input matching impedance, and the target gain ( $A_V$ ), the required input  $R_T$  value is given by solving the quadratic of 式 1.

$$R_T^2 - R_T \frac{2R_S \left( 2R_F + \frac{R_S}{2} A_V^2 \right)}{2R_F (2 + A_V) - R_S A_V (4 + A_V)} - \frac{2R_F R_S^2 A_V}{2R_F (2 + A_V) - R_S A_V (4 + A_V)} = 0 \quad (1)$$

When this value is derived, the required input side gain resistor is given by 式 2 and then the single value for  $R_{G2}$  on the non-signal input side is given by 式 3:

$$R_{G1} = \frac{2 \frac{R_F}{A_V} - R_S}{1 + \frac{R_S}{R_T}} \quad (2)$$

$$R_{G2} = \frac{2 \frac{R_F}{A_V}}{1 + \frac{R_S}{R_T}} \quad (3)$$

Using these expressions to generate a swept gain table of values results in 表 10-1, where the best standard 1% resistor values are shown to minimize input impedance and gain error to target.

**表 10-1. Swept Gain 50-Ω Input Match with  $R_F = 1.5\text{-k}\Omega$  ( $\pm 1$  Standard Values)**

GAIN (V/V)	$R_F$	$R_{G1}$	$R_T$	$R_{G2}$	$Z_{IN}$	$A_V$
0.1	1500	15000	49.9	15000	49.74	0.09973
1	1500	1500	51.1	1500	49.82	0.994
2	1500	750	52.3	768	49.98	1.978
5	1500	287	54.9	316	49.6	5.014
10	1500	137	61.9	165	50.4	10.08

Where an input impedance match is not required, simply set the input resistor to obtain the desired gain without an additional resistor to ground (remove  $R_T$  in 图 10-3). This scenario is common when coming from the output of another single-ended op amp (such as the OPA810 or OPA192). This single-ended to differential stage shows a higher input impedance than the physical  $R_G$  as given by the expression for  $Z_A$  (active input impedance) shown as 式 4.

$$Z_A = R_{G1} \frac{\left(1 + \frac{R_{G1}}{R_{G2}}\right) \left(1 + \frac{R_F}{R_{G1}}\right)}{2 + \frac{R_F}{R_{G2}}} \quad (4)$$

Using 式 4 for the gain of 1 V/V with all resistors equal to 1.5-kΩ shows an input impedance of 2 kΩ. The increased input impedance comes from the common-mode input voltage at the amplifier pins moving in the same direction as the input signal. The common-mode input voltage must move to create the current in the non-signal input  $R_G$  resistor to produce the inverted output. The current flow into the signal-side input resistor is impeded because the common-mode input voltage moves with the input signal, thus increasing the apparent input impedance in the signal input path.

### 10.1.3 Noise Analysis

The first step in the output noise analysis is to reduce the application circuit to the simplest form with equal feedback and gain setting elements to ground. [Figure 10-4](#) shows the simplest analysis circuit with the FDA and resistor noise terms to be considered.

**Figure 10-4. FDA Noise Analysis Circuit**

The noise powers are shown in [Figure 10-4](#) for each term. When the  $R_F$  and  $R_G$  terms are matched on each side, the total differential output noise is the root sum squared (RSS) of these separate terms. Using  $NG \equiv 1 + R_F / R_G$ , the total output noise is given by [Equation 5](#). Each resistor noise term is a  $4kT \times R$  power ( $4kT = 1.6E-20J$  at 290K).

$$e_o = \sqrt{(e_{ni}NG)^2 + 2(i_nR_F)^2 + 2(4kTR_FNG)} \quad (5)$$

The first term is simply the differential input spot noise times the noise gain, the second term is the input current noise terms times the feedback resistor (and because there are two uncorrelated current noise terms, the power is two times one of them), and the last term is the output noise resulting from both the  $R_F$  and  $R_G$  resistors, at again twice the value for the output noise power of each side added together. Running a wide sweep of gains when holding  $R_F$  close to 1.5 k $\Omega$  and setting the input up for a 50- $\Omega$  match gives the standard values and resulting noise listed in [Table 10-2](#).

When the gain increases, the input-referred noise approaches only the gain of the FDA input voltage noise term at 5 nV/ $\sqrt{Hz}$ .

**Table 10-2. Swept Gain of the Output- and Input-Referred Spot Noise Calculations**

GAIN (V/V)	$R_F$	$R_{G1}$	$R_T$	$R_{G2}$	$Z_{IN}$	$A_V$	$e_o$ (nV/ $\sqrt{Hz}$ )	$e_i$ (nV/ $\sqrt{Hz}$ )
0.1	1500	15000	49.9	15000	49.74	0.09973	9.15	91.53
1	1500	1500	51.1	1500	49.82	0.994	14.03	14.03
2	1500	750	52.3	768	49.98	1.978	18.99	9.49
5	1500	287	54.9	316	49.6	5.014	33.20	6.64
10	1500	137	61.9	165	50.4	10.08	55.05	5.51

### 10.1.4 Factors Influencing Harmonic Distortion

As illustrated in the swept frequency harmonic distortion plots (Figure 7-7 and Figure 7-21), the THS4561 provides extremely low distortion at lower frequencies. In general, an FDA output harmonic distortion mainly relates to the open-loop linearity in the output stage corrected by the loop gain at the fundamental frequency. When the total load impedance decreases, including the effect of the feedback resistor elements in parallel for loading purposes, the output stage open-loop linearity degrades, thus increasing the harmonic distortion; see Figure 7-9 and Figure 7-23. When the output voltage swings increase, very fine scale open-loop output stage nonlinearities increase that also degrade the harmonic distortion; see Figure 7-8 and Figure 7-22. Conversely, decreasing the target output voltage swings drops the distortion terms rapidly. Figure 7-8 and Figure 7-22 illustrate the effect of going up to a 10-V<sub>PP</sub> and 8-V<sub>PP</sub> differential output, respectively, that is more common with SAR converters.

Increasing the noise gain functions to decrease the loop gain resulting in the increasing harmonic distortion terms; see Figure 7-10 and Figure 7-24. One advantage of capacitive compensation that is typical in attenuator designs is that the noise gain is shaped up with frequency to achieve a crossover at an acceptable phase margin at higher frequencies. This technique holds the loop gain high at frequencies lower than the noise gain zero, thus improving distortion at lower frequencies.

The THS4561 does an exceptional job of converting from single-ended inputs to differential outputs with very low harmonic distortions. External resistors of 1% tolerance are used in characterization with good results. Unbalancing the feedback divider ratios does not degrade distortion directly. However, imbalanced feedback ratios convert common-mode inputs to a differential mode at the outputs that can result in increased output errors.

### 10.1.5 Input Overdrive Performance

Figure 10-5 and Figure 10-6 show a 2-V and a 2X output overdrive triangular waveform, respectively, for the THS4561. When the output maximum swing is reached at approximately the supply values, increasing input voltage beyond this condition turns on the internal protection diodes across the two input pins. The internal protection diodes are two diodes in series in both polarities. This feature clamps the maximum differential voltage across the inputs to approximately 1.5 V when the output is limited at the supplies but the input exceeds the available range. The input resistors on both sides limit the current flow in the internal diodes under these conditions.

D016  
V<sub>S</sub> = 12 V, Single-ended to differential gain of 2, 2-V output overdrive,  
overdrive recovery = 250 ns

**Figure 10-5. Overdrive Recovery Performance**

D034  
V<sub>S</sub> = 5 V, Single-ended to differential gain of 2, 2x input overdrive,  
overdrive recovery = 210 ns

**Figure 10-6. Overdrive Recovery Performance**

## 10.2 Typical Application

One common application for the THS4561 is to take a single-ended, high  $V_{PP}$  voltage swing (from a high-voltage precision amplifier such as the OPA810 or OPA192) and deliver that swing to precision SAR ADC as a single-ended to differential conversion with output common-mode control and implement an active 2nd-order multiple feedback (MFB) filter design. Designing for a 16- $V_{PP}$  maximum input down to an 8- $V_{PP}$  differential swing requires a gain of 0.5 V/V. Targeting a 170-kHz Butterworth response with the RC elements tilted towards low noise gives the example design of [Figure 10-7](#). The  $V_{CM}$  control is set to half of a 4.096-V reference, which is typical for 5-V differential SAR applications. With the high voltage capabilities of the THS4561, the design can be easily adopted for 20- $V_{PP}$  input swing to the FDA for a full 10- $V_{PP}$  swing into 5-V differential SAR ADC by simply using wider power supplies for the THS4561 to allow for increased output swing headroom with minimal performance degradation.

**Figure 10-7. MFB Filter Driving an ADC Application:  
Example 170-kHz Butterworth Response**

### 10.2.1 Design Requirements

The requirements for this application are:

- Single-ended to differential conversion
- Attenuation by 0.5-V/V gain
- Active filter set to a Butterworth, 170-kHz response shape
- Output RC elements set by SAR input requirements (not part of the filter design)
- Filter element resistors and capacitors are set to limit added noise over the THS4561 and noise peaking

### 10.2.2 Detailed Design Procedure

The design proceeds using the techniques and tools suggested in the [Design Methodology for MFB Filters in ADC Interface Applications application note](#). The process includes:

- Scale the resistor values to not meaningfully contribute to the output noise produced by the THS4561 by itself
- Select the RC ratios to hit the filter targets when reducing the noise gain peaking within the filter design
- Set the output resistor to 10  $\Omega$  into a 2.2-nF differential capacitor
- Add 100-pF common-mode capacitors to the load capacitor to improve common noise filtering
- Inside the loop, add 20- $\Omega$  output resistors after the filter feedback capacitor to increase the isolation to the load capacitor
- Include a place for a differential input capacitor (illustrated as 100 fF in [Figure 10-7](#))

### 10.2.3 Application Curves

[Figure 10-8](#) and [Figure 10-9](#) show the gain response and the noise results of the circuit shown in [Figure 10-7](#). [Figure 10-7](#) shows a place for a differential input capacitor (shown as 100 fF) but is not used for the simulation results shown in this

section. Results in [Figure 10-8](#) illustrate a flat Butterworth filter response at the output nodes going to the ADC. Obtaining the SNR to the ADC input pins, and assuming an 8-V<sub>PP</sub> full scale (2.83 V<sub>RMS</sub>), gives the result of [Figure 10-9](#). The 116-dB SNR and 13-μV<sub>RMS</sub> total noise shown in [Figure 10-9](#) does not limit the performance for any SAR application.

**Figure 10-8. Gain Plot for a 170-kHz Butterworth Filter**

**Figure 10-9. Signal-to-Noise Ratio and Total Noise Plot**

## 11 Power Supply Recommendations

The THS4561 is principally intended to operate with a nominal single-supply voltage of 3 V to 12 V. Supply voltage tolerances are supported with the specified operating range of 2.85 V (10% low on a 3-V nominal supply) and 12.6 V (5% high on a 12-V nominal supply). Supply decoupling is required, as described in [Section 8.7](#). Split (or bipolar) supplies can be used with the THS4561, as long as the total value across the device remains less than that specified in [Section 7.3](#).

Using a negative supply to deliver a true swing to ground output when driving SAR ADCs can be desired. Although the THS4561 quotes a rail-to-rail output, linear operation requires approximately 200-mV headroom to the supply rails. One easy option for extending the linear output swing to ground is to provide the small negative supply voltage required using the [LM7705](#) fixed -230-mV, negative-supply generator. This low-cost, fixed, negative-supply generator can accept a 3-V to 5-V positive supply and provides a fixed -230-mV supply for the negative power supply. Using the LM7705 provides an effective solution, as discussed in the [Extending Rail-to-Rail Output Range for Fully Differential Amplifiers to Include True Zero Volts](#) reference guide.

## 12 Layout

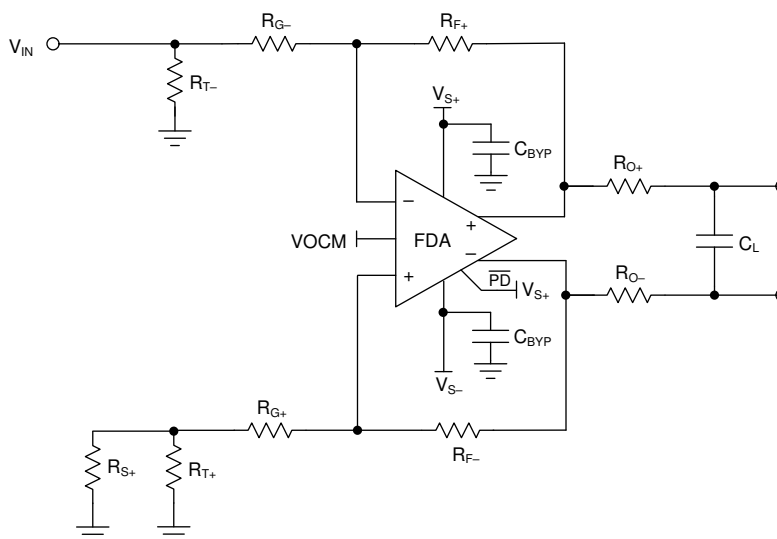

### 12.1 Layout Guidelines

#### 12.1.1 Board Layout Recommendations

Similar to all high-speed devices, best system performance is achieved with close attention to board layout. The provides a good example of high-frequency layout techniques as a reference. This EVM includes numerous extra elements and features for characterization purposes that may not apply to some applications. General high-speed signal path layout suggestions include:

- Continuous ground planes are preferred for signal routing with matched impedance traces for longer runs; however, both ground and power planes must be opened up around the capacitive sensitive input and output device pins. When the signal goes to a resistor, parasitic capacitance becomes more of a band-limiting issue and less of a stability issue.
- Good high-frequency decoupling capacitors (0.1  $\mu\text{F}$ ) are required to a ground plane at the device power pins. Additional higher-value capacitors (2.2  $\mu\text{F}$ ) are also required but can be placed further from the device power pins and shared among devices. For best high-frequency decoupling, consider X2Y supply decoupling capacitors that offer a much higher self-resonance frequency over standard capacitors.
- Differential signal routing over any appreciable distance must use microstrip layout techniques with matched impedance traces.
- The input summing junctions are very sensitive to parasitic capacitance. Any  $R_G$  elements must connect into the summing junction with minimal trace length to the device pin side of the resistor. The other side of the  $R_G$  elements can have more trace length if needed to the source or to GND.

### 13.1 ドキュメントの更新通知を受け取る方法

ドキュメントの更新についての通知を受け取るには、[ti.com](http://ti.com) のデバイス製品フォルダを開いてください。「更新の通知を受け取る」をクリックして登録すると、変更されたすべての製品情報に関するダイジェストを毎週受け取れます。変更の詳細については、修正されたドキュメントに含まれている改訂履歴をご覧ください。

### 13.2 サポート・リソース

**TI E2E™ サポート・フォーラム**は、エンジニアが検証済みの回答と設計に関するヒントをエキスパートから迅速かつ直接得ることができる場所です。既存の回答を検索したり、独自の質問をしたりすることで、設計に必要な支援を迅速に得ることができます。

リンクされているコンテンツは、該当する貢献者により、現状のまま提供されるものです。これらは TI の仕様を構成するものではなく、必ずしも TI の見解を反映したものではありません。TI の[使用条件](#)を参照してください。

### 13.3 Trademarks

TI E2E™ is a trademark of Texas Instruments.

すべての商標は、それぞれの所有者に帰属します。

### 13.4 静電気放電に関する注意事項

この IC は、ESD によって破損する可能性があります。テキサス・インスツルメンツは、IC を取り扱う際には常に適切な注意を払うことを推奨します。正しい ESD 対策をとらないと、デバイスを破損するおそれがあります。

ESD による破損は、わずかな性能低下からデバイスの完全な故障まで多岐にわたります。精密な IC の場合、パラメータがわずかに変化するだけで公表されている仕様から外れる可能性があるため、破損が発生しやすくなっています。

### 13.5 用語集

**TI 用語集** この用語集には、用語や略語の一覧および定義が記載されています。

## 14 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

## PACKAGING INFORMATION

Orderable part number	Status (1)	Material type (2)	Package   Pins	Package qty   Carrier	RoHS (3)	Lead finish/ Ball material (4)	MSL rating/ Peak reflow (5)	Op temp (°C)	Part marking (6)

<sup>(1)</sup> **Status:** For more details on status, see our [product life cycle](#).

<sup>(2)</sup> **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

<sup>(3)</sup> **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

<sup>(4)</sup> **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

<sup>(5)</sup> **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

<sup>(6)</sup> **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative

and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

**DGK0008A****PACKAGE OUTLINE****VSSOP - 1.1 mm max height**

SMALL OUTLINE PACKAGE

4214862/A 04/2023

**NOTES:**

PowerPAD is a trademark of Texas Instruments.

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm per side.
4. This dimension does not include interlead flash. Interlead flash shall not exceed 0.25 mm per side.
5. Reference JEDEC registration MO-187.
