
When the timer is counting down and it reaches the timeout event (0x0), the timer reloads its start value from the **GPTMTnILR** and the **GPTMTnPR** registers on the next cycle. When the timer is counting up and it reaches the timeout event (the value in the **GPTMTnILR** and the optional

**GPTMTnPR** registers), the timer reloads with 0x0. If configured to be a one-shot timer, the timer stops counting and clears the TnEN bit in the **GPTMCTL** register. If configured as a periodic timer, the timer starts counting again on the next cycle.

In periodic, snap-shot mode (TnMR field is 0x2 and the TnSNAPS bit is set in the **GPTMTnMR** register), the value of the timer at the time-out event is loaded into the **GPTMTnR** register and the value of the prescaler is loaded into the **GPTMTnPS** register. The free-running counter value is shown in the **GPTMTnV** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry by examining the snapshot values and the current value of the free-running timer. Snapshot mode is not available when the timer is configured in one-shot mode.

In addition to reloading the count value, the GPTM can generate interrupts, CCP outputs and triggers when it reaches the time-out event. The GPTM sets the TnTORIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 981), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 987). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register (see page 978), the GPTM also sets the TnTOMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 984). The time-out interrupt can be disabled entirely by setting the TnCINTD bit in the **GPTM Timer n Mode (GPTMTnMR)** register. In this case, the TnTORIS bit does not even set in the **GPTMRIS** register.

By setting the TnMIE bit in the **GPTMTnMR** register, an interrupt condition can also be generated when the Timer value equals the value loaded into the **GPTM Timer n Match (GPTMTnMATCHR)** and **GPTM Timer n Prescale Match (GPTMTnPMR)** registers. This interrupt has the same status, masking, and clearing functions as the time-out interrupt, but uses the match interrupt bits instead (for example, the raw interrupt status is monitored via TnMRIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register). Note that the interrupt status bits are not updated by the hardware unless the TnMIE bit in the **GPTMTnMR** register is set, which is different than the behavior for the time-out interrupt. The ADC trigger is enabled by setting the TnOTE bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 664.

The TCACT field of the **GPTM Timer n Mode (GPTMTnMR)** register can be configured to clear, set or toggle an output on a time-out event.

If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting down, the counter loads the new value on the next clock cycle and continues counting from the new value if the TnILD bit in the **GPTMTnMR** register is clear. If the TnILD bit is set, the counter loads the new value after the next timeout. If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting up, the timeout event is changed on the next cycle to the new value. If software updates the **GPTM Timer n Value (GPTMTnV)** register while the counter is counting up or down, the counter loads the new value on the next clock cycle and continues counting from the new value. If software updates the **GPTMTnMATCHR** or the **GPTMTnPMR** registers, the new values are reflected on the next clock cycle if the TnMRSU bit in the **GPTMTnMR** register is clear. If the TnMRSU bit is set, the new value will not take effect until the next timeout.

If the TnSTALL bit in the **GPTMCTL** register is set and the RTCEN bit is not set in the **GPTMCTL** register, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution. If the RTCEN bit is set, it prevents the TnSTALL bit from freezing the count when the processor is halted by the debugger.

The following table shows a variety of configurations for a 16-bit free-running timer while using the prescaler. All values assume a 120-MHz clock with  $T_c=8.33$  ns (clock period). The prescaler can only be used when a 16/32-bit timer is configured in 16-bit mode.

**Table 13-5. 16-Bit Timer With Prescaler Configurations**

| Prescale (8-bit value) | # of Timer Clocks (Tc) <sup>a</sup> | Max Time | Units |
|------------------------|-------------------------------------|----------|-------|
| 00000000               | 1                                   | 0.548258 | ms    |
| 00000001               | 2                                   | 1.096517 | ms    |
| 00000010               | 3                                   | 1.644775 | ms    |
| -----                  | --                                  | --       | --    |
| 11111101               | 254                                 | 139.2576 | ms    |
| 11111110               | 255                                 | 139.8059 | ms    |
| 11111111               | 256                                 | 140.3541 | ms    |

a. Tc is the clock period.

### **Timer Compare Action Mode**

The timer compare mode is an extension to the GPTM's existing one-shot and periodic modes. This mode can be used when an application requires a pin change state at some time in the future, regardless of the processor state. The compare mode does not operate when the PWM mode is active and is mutually exclusive to the PWM mode. The compare mode is enabled when the TAMR field is set to 0x1 or 0x2 (one-shot or periodic), the TnAMS bit is 0 (capture or compare mode) and the TCACT field is nonzero in the **GPTM Timer n Mode (GPTMTnMR)** register. Depending on the TCACT encoding, the timer can perform a set, clear or toggle on the corresponding CCPn pin when a timer match occurs. In 16-bit mode, the corresponding CCP pin can have an action applied, but when operating in 32-bit mode, the action can only be applied to the even CCP pin.

The TCACT field can be changed while the GPTM is enabled to generate different combinations of actions. For example, during a periodic event, encodings TCACT = 0x6 or 0x7 can be used to force the initial state of the CCPn pin before the first interrupt and following that, TCACT=0x2 and TCACT=0x3 can be used (alternately) to change the sense of the pin for the subsequent toggle, while possible changing load value for the next period.

The time-out interrupts used for one-shot and periodic modes are used in the compare action modes. Thus, the TnTORIS bits in the **GPTMRIS** register are triggered if the appropriate mask bits are set in the **GPTMIM** register.

### **13.3.3.2 Real-Time Clock Timer Mode**

In Real-Time Clock (RTC) mode, the concatenated versions of the Timer A and Timer B registers are configured as an up-counter. When RTC mode is selected for the first time after reset, the counter is loaded with a value of 0x1. All subsequent load values must be written to the **GPTM Timer n Interval Load (GPTMTnILR)** registers (see page 989). If the **GPTMTnILR** register is loaded with a new value, the counter begins counting at that value and rolls over at the fixed value of 0xFFFFFFFF. Table 13-6 on page 946 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 13-6. Counter Values When the Timer is Enabled in RTC Mode**

| Register        | Count Down Mode | Count Up Mode |
|-----------------|-----------------|---------------|
| <b>GPTMTnR</b>  | Not available   | 0x1           |
| <b>GPTMTnV</b>  | Not available   | 0x1           |
| <b>GPTMTnPS</b> | Not available   | Not available |

The input clock on a CCP0 input is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1-Hz rate and is passed along to the input of the counter.

When software writes the TAEN bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x1. When the current count value matches the preloaded value in the **GPTMTnMATCHR** registers, the GPTM asserts the RTCRIS bit in **GPTMRIS** and continues counting until either a hardware reset, or it is disabled by software (clearing the TAEN bit). When the timer value reaches the terminal count, the timer rolls over and continues counting up from 0x0. If the RTC interrupt is enabled in **GPTMIMR**, the GPTM also sets the RTCMIS bit in **GPTMMIS** and generates a controller interrupt. The status flags are cleared by writing the RTCCINT bit in **GPTMICR**.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

In addition to generating interrupts, the RTC can generate a  $\mu$ DMA trigger. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 664.

### 13.3.3.3 Input Edge-Count Mode

**Note:** For rising-edge detection, the input signal must be High for at least two clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low for at least two clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the frequency.

In Edge-Count mode, the timer is configured as a 24-bit up- or down-counter including the optional prescaler with the upper count value stored in the **GPTM Timer n Prescale (GPTMTnPR)** register and the lower bits in the **GPTMTnR** register. In this mode, the timer is capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge-Count mode, the TnCMR bit of the **GPTMTnMR** register must be cleared. The type of edge that the timer counts is determined by the TnEVENT fields of the **GPTMCTL** register. During initialization in down-count mode, the **GPTMTnMATCHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted. In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Note that when executing an up-count, that the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**. Table 13-7 on page 947 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 13-7. Counter Values When the Timer is Enabled in Input Edge-Count Mode**

| Register       | Count Down Mode                                      | Count Up Mode |
|----------------|------------------------------------------------------|---------------|
| <b>GPTMTnR</b> | <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> | 0x0           |
| <b>GPTMTnV</b> | <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> | 0x0           |

When software writes the TnEN bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements or increments the counter by 1 until the event count matches **GPTMTnMATCHR** and **GPTMTnPMR**. When the counts match, the GPTM asserts the CnMRIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode match interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the CnMMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In up-count mode, the current count of the input events is held in both the **GPTMTnR** and **GPTMTnV** registers. In down-count mode, the current count of the input events can be obtained by subtracting the **GPTMTnR** or **GPTMTnV** from the value made up of the **GPTMTnPR** and **GPTMTnILR** register combination.

In addition to generating interrupts, an ADC and/or a  $\mu$ DMA trigger can be generated. The ADC trigger is enabled by setting the Tn0TE bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The  $\mu$ DMA trigger is enabled by

configuring and enabling the appropriate  $\mu$ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 664.

After the match value is reached in down-count mode, the counter is then reloaded using the value in **GPTMTnILR** and **GPTMTnPR** registers, and stopped because the GPTM automatically clears the TnEN bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until TnEN is re-enabled by software. In up-count mode, the timer is reloaded with 0x0 and continues counting.

Figure 13-2 on page 948 shows how Input Edge-Count mode works. In this case, the timer start value is set to **GPTMTnILR** = 0x000A and the match value is set to **GPTMTnMATCHR** = 0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted because the timer automatically clears the TnEN bit after the current count matches the value in the **GPTMTnMATCHR** register.

**Figure 13-2. Input Edge-Count Mode Example, Counting Down**

#### 13.3.3.4 Input Edge-Time Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Time mode, the timer is configured as a 24-bit up- or down-counter including the optional prescaler with the upper timer value stored in the **GPTMTnPR** register and the lower bits in the **GPTMTnILR** register. In this mode, the timer is initialized to the value loaded in the **GPTMTnILR** and **GPTMTnPR** registers when counting down and 0x0 when counting up. The timer is capable of capturing three types of events: rising edge, falling edge, or both. The timer is placed into Edge-Time mode by setting the TnCMR bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the TnEVENT fields of the **GPTMCTL** register. Table 13-8 on page 949 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 13-8. Counter Values When the Timer is Enabled in Input Event-Count Mode**

| Register | Count Down Mode | Count Up Mode |
|----------|-----------------|---------------|
| TnR      | GPTMTnILR       | 0x0           |
| TnV      | GPTMTnILR       | 0x0           |

When software writes the TnEN bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current timer counter value is captured in the **GPTMTnR** and **GPTMTnPS** register and is available to be read by the microcontroller. The GPTM then asserts the CnERIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the CnEMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In this mode, the **GPTMTnR** and **GPTMTnPS** registers hold the time at which the selected input event occurred while the **GPTMTnV** register holds the free-running timer value. These registers can be read to determine the time that elapsed between the interrupt assertion and the entry into the ISR.

In addition to generating interrupts, an ADC and/or a  $\mu$ DMA trigger can be generated. The ADC trigger is enabled by setting the TnOTE bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The  $\mu$ DMA trigger is enabled by configuring the appropriate  $\mu$ DMA channel as well as the type of trigger selected in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 664.

After an event has been captured, the timer does not stop counting. It continues to count until the TnEN bit is cleared. When the timer reaches the timeout value, it is reloaded with 0x0 in up-count mode and the value from the **GPTMTnILR** and **GPTMTnPR** registers in down-count mode.

Figure 13-3 on page 950 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers, and is held there until another rising edge is detected (at which point the new count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers).

**Figure 13-3. 16-Bit Input Edge-Time Mode Example**

**Note:** When operating in Edge-time mode, the counter uses a modulo  $2^{24}$  count if prescaler is enabled or  $2^{16}$ , if not. If there is a possibility the edge could take longer than the count, then another timer configured in periodic-timer mode can be implemented to ensure detection of the missed edge. The periodic timer should be configured in such a way that:

- The periodic timer cycles at the same rate as the edge-time timer
- The periodic timer interrupt has a higher interrupt priority than the edge-time timeout interrupt.
- If the periodic timer interrupt service routine is entered, software must check if an edge-time interrupt is pending and if it is, the value of the counter must be subtracted by 1 before being used to calculate the snapshot time of the event.

### 13.3.3.5 PWM Mode

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a 24-bit down-counter with a start value (and thus period) defined by the **GPTMTnILR** and **GPTMTnPR** registers. In this mode, the PWM frequency and period are synchronous events and therefore guaranteed to be glitch free. PWM mode is enabled with the **GPTMTnMR** register by setting the TnAMS bit to 0x1, the TnCMR bit to 0x0, and the TnMR field to 0x2. Table 13-9 on page 950 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 13-9. Counter Values When the Timer is Enabled in PWM Mode**

| Register       | Count Down Mode  | Count Up Mode |
|----------------|------------------|---------------|
| <b>GPTMTnR</b> | <b>GPTMTnILR</b> | Not available |
| <b>GPTMTnV</b> | <b>GPTMTnILR</b> | Not available |

When software writes the TnEN bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0 state. Alternatively, if the TnWOT bit is set in the **GPTMTnMR** register, once the TnEN bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger

Mode” on page 953). On the next counter cycle in periodic mode, the counter reloads its start value from the **GPTMTnILR** and **GPTMTnPR** registers and continues counting until disabled by software clearing the TnEN bit in the **GPTMCTL** register. The timer is capable of generating interrupts based on three types of events: rising edge, falling edge, or both. The event is configured by the TnEVENT field of the **GPTMCTL** register, and the interrupt is enabled by setting the TnPWMIE bit in the **GPTMTnMR** register. When the event occurs, the CnERIS bit is set in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the CnEMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. Note that the interrupt status bits are not updated unless the TnPWMIE bit is set.

In addition, when the TnPWMIE bit is set and a capture event occurs, the Timer automatically generates triggers to the ADC and DMA if the trigger capability is enabled by setting the Tn0TE bit in the **GPTMCTL** register and the CnEDMAEN bit in the **GPTMDMAEV** register, respectively.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** and **GPTMTnPR** registers (its start state), and is deasserted when the counter value equals the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Software has the capability of inverting the output PWM signal by setting the TnPWML bit in the **GPTMCTL** register.

**Note:** If PWM output inversion is enabled, edge detection interrupt behavior is reversed. Thus, if a positive-edge interrupt trigger has been set and the PWM inversion generates a positive edge, no event-trigger interrupt asserts. Instead, the interrupt is generated on the negative edge of the PWM signal.

Figure 13-4 on page 952 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and **TnPWML** = 0 (duty cycle would be 33% for the **TnPWML** = 1 configuration). For this example, the start value is **GPTMTnILR**=0xC350 and the match value is **GPTMTnMATCHR**=0x411A.

**Figure 13-4. 16-Bit PWM Mode Example**

When synchronizing the timers using the **GPTMSYNC** register, the timer must be properly configured to avoid glitches on the CCP outputs. Both the TnPLO and the TnMRSU bits must be set in the **GPTMTnMR** register. Figure 13-5 on page 952 shows how the CCP output operates when the TnPLO and TnMRSU bits are set and the **GPTMTnMATCHHR** value is greater than the **GPTMTnILR** value.

**Figure 13-5. CCP Output, GPTMTnMATCHHR > GPTMTnILR**

Figure 13-6 on page 953 shows how the CCP output operates when the PLO and MRSU bits are set and the **GPTMTnMATCHHR** value is the same as the **GPTMTnILR** value. In this situation, if the **PLO** bit is 0, the CCP signal goes high when the **GPTMTnILR** value is loaded and the match would be essentially ignored.

**Figure 13-6. CCP Output, GPTMTnMATCHR = GPTMTnILR**

Figure 13-7 on page 953 shows how the CCP output operates when the PL0 and MRSU bits are set and the **GPTMTnILR** is greater than the **GPTMTnMATCHR** value.

**Figure 13-7. CCP Output, GPTMTnILR > GPTMTnMATCHR**

### 13.3.4 Wait-for-Trigger Mode

The Wait-for-Trigger mode allows daisy chaining of the timer modules such that once configured, a single timer can initiate multiple timing events using the Timer triggers. Wait-for-Trigger mode is enabled by setting the TnWOT bit in the **GPTMTnMR** register. When the TnWOT bit is set, Timer N+1 does not begin counting until the timer in the previous position in the daisy chain (Timer N) reaches its time-out event. The daisy chain is configured such that GPTM1 always follows GPTM0, GPTM2 follows GPTM1, and so on. If Timer A is configured as a 32-bit (16/32-bit mode) timer (controlled by the GPTMCFG field in the **GPTMCFG** register), it triggers Timer A in the next module. If Timer A is configured as a 16-bit (16/32-bit mode) timer, it triggers Timer B in the same module, and Timer B triggers Timer A in the next module. Figure 13-8 on page 954 shows how the GPTMCFG bit affects the daisy chain. This function is valid for one-shot, periodic, and PWM modes.

**Note:** If the application requires cyclical daisy-chaining, the TAWOT bit in the **GPTMTAMR** register of Timer 0 can be set. In this case, Timer 0 waits for a trigger from the last timer module in the chain.

### 13.3.5 Synchronizing GP Timer Blocks

The **GPTM Synchronizer Control (GPTMSYNC)** register in the GPTM0 block can be used to synchronize selected timers to begin counting at the same time. Setting a bit in the **GPTMSYNC** register causes the associated timer to perform the actions of a timeout event. An interrupt is not generated when the timers are synchronized. If a timer is being used in concatenated mode, only the bit for Timer A must be set in the **GPTMSYNC** register.

**Note:** All timers must use the same clock source for this feature to work correctly.

Table 13-10 on page 954 shows the actions for the timeout event performed when the timers are synchronized in the various timer modes.

### Table 13-10. Timeout Actions for GPTM Modes

| Mode                                           | Count Dir | Time Out Action   |
|------------------------------------------------|-----------|-------------------|
| 32-bit One-Shot<br>(concatenated timers)       | —         | N/A               |
| 32-bit Periodic<br>(concatenated timers)       | Down      | Count value = ILR |
|                                                | Up        | Count value = 0   |
| 32-bit RTC<br>(concatenated timers)            | Up        | Count value = 0   |
| 16- bit One Shot<br>(individual/split timers)  | —         | N/A               |
| 16-bit Periodic<br>(individual/split timers)   | Down      | Count value = ILR |
|                                                | Up        | Count value = 0   |
| 16-bit Edge-Count<br>(individual/split timers) | Down      | Count value = ILR |
|                                                | Up        | Count value = 0   |
| 16- bit Edge-Time<br>(individual/split timers) | Down      | Count value = ILR |
|                                                | Up        | Count value = 0   |
| 16-bit PWM                                     | Down      | Count value = ILR |

### 13.3.6 DMA Operation

The timers each have a dedicated  $\mu$ DMA channel and can provide a request signal to the  $\mu$ DMA controller. Pulse requests are generated by a timer via its own `dma_req` signal. A `dma_done` signal is provided from the  $\mu$ DMA to each timer to indicate transfer completion and trigger a  $\mu$ DMA done interrupt (DMAnRIS) in the **GPTM Raw Interrupt Status Register (GPTMRIS) register**. The request is a burst type and occurs whenever a timer raw interrupt condition occurs. The arbitration size of the  $\mu$ DMA transfer should be set to the amount of data that should be transferred whenever a timer event occurs.

For example, to transfer 256 items, 8 items at a time every 10 ms, configure a timer to generate a periodic timeout at 10 ms. Configure the  $\mu$ DMA transfer for a total of 256 items, with a burst size of 8 items. Each time the timer times out, the  $\mu$ DMA controller transfers 8 items, until all 256 items have been transferred. Refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 659 for more details about programming the  $\mu$ DMA controller.

A **GPTM DMA Event (GPTMDMAEV) register** is provided to enable the types of events that can cause a `dma_req` signal assertion by the timer module. Application software can enable a `dma_req` trigger for a match, capture or time-out event for each timer using the **GPTMDMAEV** register. For an individual timer, all active timer trigger events that have been enabled through the **GPTMDMAEV** register are ORed together to create a single `dma_req` pulse that is sent to the  $\mu$ DMA. When the  $\mu$ DMA transfer has completed, a `dma_done` signal is sent to the timer resulting in a DMAnRIS bit set in the **GPTMRIS** register.

### 13.3.7 ADC Operation

The timer has the capability to trigger the ADC when the Tn0TE bit is set in the **GPTMCTL** register at offset 0x00C. The **GPTM ADC Event (GPTMADCEV) register** is additionally provided so that the type of ADC trigger can be defined. For example, by setting the CBMADCEN bit in the **GPTMADCEV** register, a trigger pulse will be sent to the ADC whenever a Capture Match event occurs in GPTM B. Similar to the  $\mu$ DMA operation, all active trigger events that have also been enabled in the **GPTMADCEV** register are ORed together to create an ADC trigger pulse.

### 13.3.8 Accessing Concatenated 16/32-Bit GPTM Register Values

The GPTM is placed into concatenated mode by writing a 0x0 or a 0x1 to the GPTMCFG bit field in the **GPTM Configuration (GPTMCFG) register**. In both configurations, certain 16/32-bit GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM Timer A Interval Load (GPTMTAILR) register** [15:0], see page 989
- **GPTM Timer B Interval Load (GPTMTBILR) register** [15:0], see page 990
- **GPTM Timer A (GPTMTAR) register** [15:0], see page 997
- **GPTM Timer B (GPTMTBR) register** [15:0], see page 998
- **GPTM Timer A Value (GPTMTAV) register** [15:0], see page 999
- **GPTM Timer B Value (GPTMTBV) register** [15:0], see page 1000
- **GPTM Timer A Match (GPTMTAMATCHR) register** [15:0], see page 991
- **GPTM Timer B Match (GPTMTBMATCHR) register** [15:0], see page 992

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

**GPTMTBILR**[15:0] : **GPTMTAILR**[15:0]

Likewise, a 32-bit read access to **GPTMTAR** returns the value:

**GPTMTBILR**[15:0] : **GPTMTAR**[15:0]

A 32-bit read access to **GPTMTAV** returns the value:

**GPTMTBILR**[15:0] : **GPTMTAV**[15:0]

## 13.4 Initialization and Configuration

To use a GPTM, the appropriate **TIMERN** bit must be set in the **RCGCTIMER** register (see page 371). If using any CCP pins, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (see page 373). To find out which GPIO port to enable, refer to Table 25-4 on page 1556. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the CCP signals to the appropriate pins (see page 771 and Table 25-5 on page 1569).

This section shows module initialization and configuration examples for each of the supported timer modes.

### 13.4.1 One-Shot/Periodic Timer Mode

The GPTM is configured for One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the **TnEN** bit in the **GPTMCTL** register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0000.
3. Configure the **TnMR** field in the **GPTM Timer n Mode Register (GPTMTnMR)**:
  - a. Write a value of 0x1 for One-Shot mode.
  - b. Write a value of 0x2 for Periodic mode.
4. Optionally configure the **TnSNAPS**, **TnWOT**, **TnMTE**, and **TnCDIR** bits in the **GPTMTnMR** register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down. In addition, if using CCP pins, the **TnACT** field can be programmed to configure the compare action.
5. Load the start value into the **GPTM Timer n Interval Load Register (GPTMTnILR)**.
6. If interrupts are required, set the appropriate bits in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the **TnEN** bit in the **GPTMCTL** register to enable the timer and start counting.
8. Poll the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

If the TnMIE bit in the **GPTMTnMR** register is set, the RTCRIS bit in the **GPTMRIS** register is set, and the timer continues counting. In One-Shot mode, the timer stops counting after the time-out event. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode reloads the timer and continues counting after the time-out event.

### 13.4.2 Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on an even CCP input. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the TAEN bit is cleared) before making any changes.
2. If the timer has been operating in a different mode prior to this, clear any residual set bits in the **GPTM Timer n Mode (GPTMTnMR)** register before reconfiguring.
3. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0001.
4. Write the match value to the **GPTM Timer n Match Register (GPTMTnMATCHR)**.
5. Set/clear the RTCEN and TnSTALL bit in the **GPTM Control Register (GPTMCTL)** as needed.
6. If interrupts are required, set the RTCIM bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the TAEN bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTnMATCHR** register, the GPTM asserts the RTCRIS bit in the **GPTMRIS** register and continues counting until Timer A is disabled or a hardware reset. The interrupt is cleared by writing the RTCCINT bit in the **GPTMICR** register. Note that if the **GPTMTnILR** register is loaded with a new value, the timer begins counting at this new value and continues until it reaches 0xFFFF.FFFF, at which point it rolls over.

### 13.4.3 Input Edge-Count Mode

A timer is configured to Input Edge-Count mode by the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the TnCMR field to 0x0 and the TnMR field to 0x3.
4. Configure the type of event(s) that the timer captures by writing the TnEVENT field of the **GPTM Control (GPTMCTL)** register.
5. Program registers according to count direction:
  - In down-count mode, the **GPTMTnMATCHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted.
  - In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Note that when executing an up-count, the value of the **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

6. If interrupts are required, set the CnMIM bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
7. Set the TnEN bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
8. Poll the CnMRIS bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the CnMCINT bit of the **GPTM Interrupt Clear (GPTMICR)** register.

When counting down in Input Edge-Count Mode, the timer stops after the programmed number of edge events has been detected. To re-enable the timer, ensure that the TnEN bit is cleared and repeat steps 4 through 8.

#### 13.4.4 Input Edge Time Mode

A timer is configured to Input Edge Time mode by the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the TnCMR field to 0x1 and the TnMR field to 0x3 and select a count direction by programming the TnCDIR bit.
4. Configure the type of event that the timer captures by writing the TnEVENT field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. If interrupts are required, set the CnEIM bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the TnEN bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
9. Poll the CnERIS bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the CnECINT bit of the **GPTM Interrupt Clear (GPTMICR)** register. The time at which the event happened can be obtained by reading the **GPTM Timer n (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register and clearing the TnILD bit in the **GPTMTnMR** register. The change takes effect at the next cycle after the write.

#### 13.4.5 PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the TnAMS bit to 0x1, the TnCMR bit to 0x0, and the TnMR field to 0x2.

4. Configure the output state of the PWM signal (whether or not it is inverted) in the TnPWML field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. If PWM interrupts are used, configure the interrupt condition in the TnEVENT field in the **GPTMCTL** register and enable the interrupts by setting the TnPWMIE bit in the **GPTMTnMR** register. Note that edge detect interrupt behavior is reversed when the PWM output is inverted (see page 971).
7. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
8. Load the **GPTM Timer n Match (GPTMTnMATCHR)** register with the match value.
9. Set the TnEN bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Time mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

## 13.5 Register Map

Table 13-11 on page 959 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- 16/32-bit Timer 0: 0x4003.0000
- 16/32-bit Timer 1: 0x4003.1000
- 16/32-bit Timer 2: 0x4003.2000
- 16/32-bit Timer 3: 0x4003.3000
- 16/32-bit Timer 4: 0x4003.4000
- 16/32-bit Timer 5: 0x4003.5000
- 16/32-bit Timer 6: 0x400E.0000
- 16/32-bit Timer 7: 0x400E.1000

Note that the GP Timer module clock must be enabled before the registers can be programmed (see page 371). There must be a delay of 3 system clocks after the Timer module clock is enabled before any Timer module registers are accessed.

**Table 13-11. Timers Register Map**

| Offset | Name     | Type | Reset       | Description         | See page |
|--------|----------|------|-------------|---------------------|----------|
| 0x000  | GPTMCFG  | RW   | 0x0000.0000 | GPTM Configuration  | 961      |
| 0x004  | GPTMTAMR | RW   | 0x0000.0000 | GPTM Timer A Mode   | 962      |
| 0x008  | GPTMTBMR | RW   | 0x0000.0000 | GPTM Timer B Mode   | 967      |
| 0x00C  | GPTMCTL  | RW   | 0x0000.0000 | GPTM Control        | 971      |
| 0x010  | GPTMSYNC | RW   | 0x0000.0000 | GPTM Synchronize    | 975      |
| 0x018  | GPTMIMR  | RW   | 0x0000.0000 | GPTM Interrupt Mask | 978      |

Table 13-11. Timers Register Map (*continued*)

| Offset | Name         | Type | Reset       | Description                    | See page |
|--------|--------------|------|-------------|--------------------------------|----------|
| 0x01C  | GPTMRIS      | RO   | 0x0000.0000 | GPTM Raw Interrupt Status      | 981      |

## 13.6 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

**Register 1: GPTM Configuration (GPTMCFG), offset 0x000**

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

**Important:** Bits in this register should only be changed when the TAEN and TBEN bits in the **GPTMCTL** register are cleared.

**GPTM Configuration (GPTMCFG)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x000

**Register 2: GPTM Timer A Mode (GPTMTAMR), offset 0x004**

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the TAAMS bit, clear the TACMR bit, and configure the TAMR field to 0x1 or 0x2.

This register controls the modes for Timer A when it is used individually. When Timer A and Timer B are concatenated, this register controls the modes for both Timer A and Timer B, and the contents of **GPTMTBMR** are ignored.

**Important:** Except for the TCACT bit field, all other bits in this register should only be changed when the TAEN bit in the **GPTMCTL** register is cleared.

**GPTM Timer A Mode (GPTMTAMR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000

**Register 3: GPTM Timer B Mode (GPTMTBMR), offset 0x008**

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the TBAMS bit, clear the TBCMR bit, and configure the TBMR field to 0x1 or 0x2.

This register controls the modes for Timer B when it is used individually. When Timer A and Timer B are concatenated, this register is ignored and **GPTMTAMR** controls the modes for both Timer A and Timer B.

**Important:** Except for the TCACT bit field, all other bits in this register should only be changed when the TBEN bit in the **GPTMCTL** register is cleared.

**GPTM Timer B Mode (GPTMTBMR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000

**Register 4: GPTM Control (GPTMCTL), offset 0x00C**

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

**Important:** Bits in this register should only be changed when the TnEN bit for the respective timer is cleared.

**GPTM Control (GPTMCTL)**

**Register 5: GPTM Synchronize (GPTMSYNC), offset 0x010****Note:** This register is only implemented on GPTM Module 0 only.

This register allows software to synchronize a number of timers.

**GPTM Synchronize (GPTMSYNC)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x010  
 Type RW, reset 0x0000.0000

**Register 6: GPTM Interrupt Mask (GPTMIMR), offset 0x018**

This register allows software to enable/disable GPTM controller-level interrupts. Setting a bit enables the corresponding interrupt, while clearing a bit disables it.

**GPTM Interrupt Mask (GPTMIMR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000

**Register 7: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C**

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMIMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

**Note:** The state of the **GPTMRIS** register is not affected by disabling and then re-enabling the timer using the TnEN bits in the **GPTM Control (GPTMCTL)** register. If an application requires that all or certain status bits should not carry over after re-enabling the timer, then the appropriate bits in the **GPTMRIS** register should be cleared using the **GPTMICR** register prior to re-enabling the timer. If this is not done, any status bits set in the **GPTMRIS** register and unmasked in the **GPTMIMR** register generate an interrupt once the timer is re-enabled.

**GPTM Raw Interrupt Status (GPTMRIS)**

## Register 8: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register show the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

### GPTM Masked Interrupt Status (GPTMMIS)

**Register 9: GPTM Interrupt Clear (GPTMICR), offset 0x024**

This register is used to clear the status bits in the **GPTMRIS** and **GPTMMIS** registers. Writing a 1 to a bit clears the corresponding bit in the **GPTMRIS** and **GPTMMIS** registers.

**GPTM Interrupt Clear (GPTMICR)**

**Register 10: GPTM Timer A Interval Load (GPTMTAILR), offset 0x028**

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Interval Load (GPTMTBILR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

**Register 11: GPTM Timer B Interval Load (GPTMTBILR), offset 0x02C**

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAILR** register. Reads from this register return the current value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the load value. Bits 31:16 are reserved in both cases.

**Register 12: GPTM Timer A Match (GPTMTAMATCHR), offset 0x030**

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTAILR**, determines the duty cycle of the output PWM signal.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAMATCHR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Match (GPTMTBMATCHR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBMATCHR**.

Register 13: GPTM Timer B Match (GPTMTBMATCHR), offset 0x034

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTBILR** determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTBILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTBILR**, determines the duty cycle of the output PWM signal.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAMATCHR** register. Reads from this register return the current match value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the match value. Bits 31:16 are reserved in both cases.

**Register 14: GPTM Timer A Prescale (GPTMTAPR), offset 0x038**

This register allows software to extend the range of the timers when they are used individually. When in one-shot or periodic down count modes, this register acts as a true prescaler for the timer counter. When acting as a true prescaler, the prescaler counts down to 0 before the value in the **GPTMTAR** and **GPTMTAV** registers are incremented. In all other individual/split modes, this register is a linear extension of the upper range of the timer counter, holding bits 23:16 in the 16-bit modes of the 16/32-bit GPTM.

**Register 18: GPTM Timer A (GPTMTAR), offset 0x048**

This register shows the current value of the Timer A counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B (GPTMTBR)** register). In the 16-bit Input Edge Count, Input Edge Time, and PWM modes, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTAV** register. To read the value of the prescaler in periodic snapshot mode, read the **Timer A Prescale Snapshot (GPTMTAPS)** register.

**GPTM Timer A (GPTMTAR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000

| Bit/Field | Name | Type | Reset       | Description           |
|-----------|------|------|-------------|-----------------------|
| 31:0      | TAR  | RO   | 0xFFFF.FFFF | GPTM Timer A Register |

A read returns the current value of the **GPTM Timer A Count Register**, in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Register 19: GPTM Timer B (GPTMTBR), offset 0x04C**

This register shows the current value of the Timer B counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAR** register. Reads from this register return the current value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler in Input Edge Count, Input Edge Time, and PWM modes, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTBV** register. To read the value of the prescaler in periodic snapshot mode, read the **Timer B Prescale Snapshot (GPTMTBPS)** register.

**GPTM Timer B (GPTMTBR)**

 Offset 0x04C  
 Type RO, reset 0x0000.FFFF

| Bit/Field | Name | Type | Reset       | Description           |
|-----------|------|------|-------------|-----------------------|
| 31:0      | TBR  | RO   | 0x0000.FFFF | GPTM Timer B Register |

A read returns the current value of the **GPTM Timer B Count Register**, in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Register 20: GPTM Timer A Value (GPTMTAV), offset 0x050**

When read, this register shows the current, free-running value of Timer A in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry when using the snapshot feature with the periodic operating mode. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAV** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Value (GPTMTBV)** register). In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

**GPTM Timer A Value (GPTMTAV)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x050  
 Type RW, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset       | Description        |
|-----------|------|------|-------------|--------------------|
| 31:0      | TAV  | RW   | 0xFFFF.FFFF | GPTM Timer A Value |

A read returns the current, free-running value of Timer A in all modes. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

**Note:** In 16-bit mode, only the lower 16-bits of the **GPTMTAV** register can be written with a new value. Writes to the prescaler bits have no effect.

Register 21: GPTM Timer B Value (GPTMTBV), offset 0x054

When read, this register shows the current, free-running value of Timer B in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry. When written, the value written into this register is loaded into the **GPTMTBR** register on the next clock cycle.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAV** register. Reads from this register return the current free-running value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

**Register 25: GPTM DMA Event (GPTMDMAEV), offset 0x06C**

This register allows software to enable/disable GPTM DMA trigger events. Setting a bit enables the corresponding DMA trigger, while clearing a bit disables it.

**GPTM DMA Event (GPTMDMAEV)**

**Register 28: GPTM Clock Configuration (GPTMCC), offset 0xFC8**

The **GPTMCC** register controls the clock source for the General-Purpose Timer module.

**Note:** When the ALTCLK bit is set in the **GPTMCC** register to enable using the alternate clock source, the synchronization imposes restrictions on the starting count value (down-count), terminal value (up-count) and the match value. This restriction applies to all modes of operation. Each event must be spaced by 4 Timer (ALTCLK) clock periods + 2 system clock periods. If some events do not meet this requirement, then it is possible that the timer block may need to be reset for correct functionality to be restored.

Example:  $ALTCLK = T_{PIOSC} = 62.5ns$  (16Mhz Trimmed)

$T_{hclk} = 1\mu s$  (1Mhz)

$4 * 62.5ns + 2 * 1\mu s = 2.25\mu s$   $2.25\mu s / 62.5ns = 36$  or 0x23

The minimum values for the periodic or one-shot with a match interrupt enabled are:  
**GPTMTAMATCHR = 0x23 GPTMTAILR = 0x46**

## 14 Watchdog Timers

A watchdog timer can generate a non-maskable interrupt (NMI), a regular interrupt or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way. The TM4C1290NCZAD microcontroller has two Watchdog Timer Modules, one module is clocked by the system clock (Watchdog Timer 0) and the other (Watchdog Timer 1) is clocked by the clock source programmed in the ALTCLK field of the **Alternate Clock Configuration (ALTCLKCFG)** register, System Control offset 0x138. The two modules are identical except that WDT1 is in a different clock domain, and therefore requires synchronizers. As a result, WDT1 has a bit defined in the **Watchdog Timer Control (WDTCTL)** register to indicate when a write to a WDT1 register is complete. Software can use this bit to ensure that the previous access has completed before starting the next access.

The TM4C1290NCZAD controller has two Watchdog Timer modules with the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

## 14.1 Block Diagram

Figure 14-1. WDT Module Block Diagram

## 14.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. The watchdog interrupt can be programmed to be a non-maskable interrupt (NMI) using the **INTTYPE** bit in the **WDTCTL** register. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled by setting the **RESEN** bit in the **WDTCTL** register, the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

The watchdog timer is disabled by default out of reset. To achieve maximum watchdog protection of the device, the watchdog timer can be enabled at the start of the reset vector.

### 14.2.1 Register Access Timing

Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The WRC bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for WRC=1 prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock.

## 14.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the Rn bit in the **Watchdog Timer Run Mode Clock Gating Control (RCGCWD)** register, see page 370.

The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If WDT1, wait for the WRC bit in the **WDTCTL** register to be set.
3. Set the INTEN bit (if interrupts are required) or the RESEN bit (if a reset is required after two timeouts) in the **WDTCTL** register. The Watchdog Timer starts when either of them is enabled.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

To service the watchdog, periodically reload the count value into the **WDTLOAD** register to restart the count. The interrupt can be enabled using the INTEN bit in the **WDTCTL** register to allow the processor to attempt corrective action if the watchdog is not serviced often enough. The RESEN bit in **WDTCTL** can be set so that the system resets if the failure is not recoverable using the ISR.

**Note:** The application should be sure not to modify the ALTCLK encoding in the **ALTCLKCFG** register while the WDT1 is enabled and running.

## 14.4 Register Map

Table 14-1 on page 1016 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address:

- WDT0: 0x4000.0000
- WDT1: 0x4000.1000

Note that the Watchdog Timer module clock must be enabled before the registers can be programmed (see page 370).

**Table 14-1. Watchdog Timers Register Map**

| Offset | Name            | Type | Reset                                    | Description                          | See page |

## 14.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

**Register 1: Watchdog Load (WDTLOAD), offset 0x000**

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

**Watchdog Load (WDTLOAD)**

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x000

Type RW, reset 0xFFFF.FFFF

|       |         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

|-----------|----------|------|-------------|-------------------------------------------------------------|
| 31:0      | WDTVALUE | RO   | 0xFFFF.FFFF | Watchdog Value<br>Current value of the 32-bit down counter. |

### Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled by setting the INTEN bit, all subsequent writes to the INTEN bit are ignored. The only mechanisms that can re-enable writes to this bit are a hardware reset or a software reset initiated by setting the appropriate bit in the **Watchdog Timer Software Reset (SRWD)** register.

**Important:** Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The WRC bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for WRC=1 prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock and therefore does not have a WRC bit.

#### Watchdog Control (WDTCTL)

Once enabled, all writes are ignored. Setting this bit enables the Watchdog Timer. |

**Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C**

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Write to this register when a watchdog time-out interrupt has occurred to properly service the Watchdog. Value for a read or reset is indeterminate.

**Note:** Locking the watchdog registers by using the **WDTLOCK** register does not affect the **WDTICR** register and allows interrupts to always be serviced. Thus, a write at any time of the **WDTICR** register clears the **WDTMIS** register and reloads the 32-bit counter from the **WDTLOAD** register. The **WDTICR** register should only be written when interrupts have triggered and need to be serviced.

**Watchdog Interrupt Clear (WDTICR)**

| 7:0       | reserved | RO   | 0x00      | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

## Register 8: Watchdog Lock (WDTLOCK), offset 0xC00

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers, except for the **Watchdog Test (WDTTEST)** register. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

### Watchdog Lock (WDTLOCK)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0xC00

Type RW, reset 0x0000.0000

| Bit/Field | Name    | Type | Reset       | Description   |
|-----------|---------|------|-------------|---------------|
| 31:0      | WDTLOCK | RW   | 0x0000.0000 | Watchdog Lock |

A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value reapplies the lock, preventing any register updates, except for the **WDTTEST** register. Avoid writes to the **WDTTEST** register when the watchdog registers are locked.

A read of this register returns the following values:

| Value       | Description |
|-------------|-------------|
| 0x0000.0001 | Locked      |
| 0x0000.0000 | Unlocked    |

Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

Watchdog Peripheral Identification 4 (WDTPeriphID4)

## 15 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. Two identical converter modules are included, which share 24 input channels.

The TM4C1290NCZAD ADC module features 12-bit conversion resolution and supports 24 input channels, plus an internal temperature sensor. Each ADC module contains four programmable sequencers allowing the sampling of multiple analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. In addition, the conversion value can optionally be diverted to a digital comparator module. Each ADC module provides eight digital comparators. Each digital comparator evaluates the ADC conversion value against its two user-defined values to determine the operational range of the signal. The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. A phase shifter can delay the start of sampling by a specified phase angle. When using both ADC modules, it is possible to configure the converters to start the conversions coincidentally or within a relative phase from each other, see “Sample Phase Control” on page 1045.

The TM4C1290NCZAD microcontroller provides two ADC modules with each having the following features:

- 24 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of two million samples/second
- Optional, programmable phase delay
- Sample and hold window programmability
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - PWM
  - GPIO
- Hardware averaging of up to 64 samples
- Eight digital comparators

- Converter uses two external reference signals (VREFA+ and VREFA- ) or VDDA and GNDA as the voltage reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Dedicated channel for each sample sequencer
  - ADC module uses burst requests for DMA
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate ADC clock

## 15.1 Block Diagram

The TM4C1290NCZAD microcontroller contains two identical Analog-to-Digital Converter modules. These two modules, ADC0 and ADC1, share the same 24 analog input channels. Each ADC module operates independently and can therefore execute different sample sequences, sample any of the analog input channels at any time, and generate different interrupts and triggers. Figure 15-1 on page 1039 shows how the two modules are connected to analog inputs and the system bus.

**Figure 15-1. Implementation of Two ADC Blocks**

Figure 15-2 on page 1040 provides details on the internal configuration of the ADC controls and data registers.

Figure 15-2. ADC Module Block Diagram

## 15.2 Signal Description

The following table lists the external signals of the ADC module and describes the function of each. The AINx signals are analog functions for some GPIO signals. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the ADC signals. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 723. The VREF+ and VREF- signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

Table 15-1. ADC Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                          |
|----------|------------|--------------------------|----------|-------------|--------------------------------------|

| VREFA+   | F4         | fixed                    | -        | Analog      | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 26-44 on page 1624.                                                                                                                               |
| VREFA-   | G5         | fixed                    | -        | Analog      | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 26-44 on page 1624. |

## 15.3 Functional Description

The TM4C1290NCZAD ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approaches found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the processor. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence. In addition, the  $\mu$ DMA can be used to more efficiently move data from the sample sequencers without CPU intervention.

### 15.3.1 Sample Sequencers

The sampling control and data capture is handled by the sample sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 15-2 on page 1042 shows the maximum number of samples that each sequencer can capture and its corresponding FIFO depth. Each sample that is captured is stored in the FIFO. In this implementation, each FIFO entry is a 32-bit word, with the lower 12 bits containing the conversion result.

**Table 15-2. Samples and FIFO Depth of Sequencers**

| Sequencer | Number of Samples | Depth of FIFO |
|-----------|-------------------|---------------|
| SS3       | 1                 | 1             |
| SS2       | 4                 | 4             |
| SS1       | 4                 | 4             |
| SS0       | 8                 | 8             |

For a given sample sequence, each sample is defined by bit fields in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn)**, **ADC Sample Sequence Extended Input Multiplexer Select (ADCSSEMUXn)** and **ADC Sample Sequence Control (ADCSSCTLn)** registers, where "n" corresponds to the sequence number. The **ADCSSMUXn** and **ADCSSEMUXn** fields select the input pin, while the **ADCSSCTLn** fields contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample sequencers are enabled by setting the respective **ASENn** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register and should be configured before being enabled. Sampling is then initiated by setting the **SSn** bit in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. In addition, sample sequences may be initiated on multiple ADC modules simultaneously using the **GSYNC** and **SYNCWAIT** bits in the **ADCPSSI** register during the configuration of each ADC module. For more information on using these bits, refer to page 1089.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence are allowed. In the **ADCSSCTLn** register, the **IEn** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END** bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the **END** bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFO)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTATn)** registers along with **FULL** and **EMPTY** status flags. If a write is attempted when the FIFO is full, the write does not occur and an overflow condition is indicated. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

### 15.3.2 Module Control

Outside of the sample sequencers, the remainder of the control logic is responsible for tasks such as:

- Interrupt generation
- DMA operation

- Sequence prioritization
- Trigger configuration
- Comparator configuration
- External voltage reference
- Sample phase control
- Module clocking

#### 15.3.2.1 Interrupts

The register configurations of the sample sequencers and digital comparators dictate which events generate raw interrupts, but do not have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signals are controlled by the state of the MASK bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADCRIIS)** register, which shows the raw status of the various interrupt signals; and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows active interrupts that are enabled by the **ADCIM** register. Sequencer interrupts are cleared by writing a 1 to the corresponding IN bit in **ADCISC**. Digital comparator interrupts are cleared by writing a 1 to the **ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)** register.

#### 15.3.2.2 DMA Operation

DMA may be used to increase efficiency by allowing each sample sequencer to operate independently and transfer data without processor intervention or reconfiguration.

The ADC asserts single and burst  $\mu$ DMA request signals (dma\_sreq and dma\_req) to the  $\mu$ DMA controller based on the FIFO level. The dma\_req signal is generated when the FIFO in question is half-full (that is, at 4 samples for SS0, 2 samples for SS1 and SS2, and at 1 sample for SS3). If, for example, the **ADCSSCTL0** register has six samples to transfer, a burst of four values occurs followed by two single transfers (dma\_sreq). The dma\_done signals (one per sample sequencer) are sent to the ADC to allow for a triggering of DMAINRn interrupt bits in the **ADCRIS** register. The  $\mu$ DMA is enabled for a specific sample sequencer by setting the appropriate ADENn bit in the **ADCACTSS** register at offset 0x000.

To use the  $\mu$ DMA with the ADC module, the application must enable the ADC channel through **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA.

Refer to the “Micro Direct Memory Access ( $\mu$ DMA)” on page 659 for more details about programming the  $\mu$ DMA controller.

#### 15.3.2.3 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active sample sequencer units with the same priority do not provide consistent results, so software must ensure that all active sample sequencer units have a unique priority value.

#### 15.3.2.4 Sampling Events

Sample triggering for each sample sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. Trigger sources include processor (default), analog comparators, an external signal on a GPIO specified by the **GPIO ADC Control (GPIOADCCTL)** register, a GP Timer, a

PWM generator, and continuous sampling. The processor triggers sampling by setting the SSx bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register.

Care must be taken when using the continuous sampling trigger. If a sequencer's priority is too high, it is possible to starve other lower priority sequencers. Generally, a sample sequencer using continuous sampling should be set to the lowest priority. Continuous sampling can be used with a digital comparator to cause an interrupt when a particular voltage is seen on an input.

### 15.3.2.5 Sample and Hold Window Control

The ADC module provides the capability of programming the sample and hold window of each step in a sequence through the **ADC Sample Sequence n Sample and Hold Time (ADCSSTSHn)** register. Each TSHn field can be written with a different sample and hold width, which is represented in ADC clocks. The table below gives the allowed encodings:

**Table 15-3. Sample and Hold Width in ADC Clocks**

| TSHn Encoding | N <sub>SH</sub> |
|---------------|-----------------|
| 0x0           | 4               |
| 0x1           | reserved        |
| 0x2           | 8               |
| 0x3           | reserved        |
| 0x4           | 16              |
| 0x5           | reserved        |
| 0x6           | 32              |
| 0x7           | reserved        |
| 0x8           | 64              |
| 0x9           | reserved        |
| 0xA           | 128             |
| 0xB           | reserved        |
| 0xC           | 256             |
| 0xD-0xF       | reserved        |

The ADC conversion frequency is a function of the Sample and Hold number, given by the following equation:

$$F_{\text{CONV}} = 1 / ((N_{\text{SH}} + 12) * T_{\text{ADC}})$$

where:

- N<sub>SH</sub> is the sample and hold width in ADC clocks
- T<sub>ADC</sub> is the ADC conversion clock period, which is the inverse of the ADC clock frequency F<sub>ADC</sub>

Now, the maximum allowable external source resistance (R<sub>S</sub>) also changes with the value of N<sub>SH</sub>, as the total settling time of the input circuitry must be fast enough to settle to within the ADC resolution in a single sampling interval. The input circuitry includes the external source resistance as well as the input resistance and capacitance of the ADC (R<sub>ADC</sub> and C<sub>ADC</sub>).

The values for R<sub>S</sub> and F<sub>CONV</sub> for varying N<sub>SH</sub> values, with F<sub>ADC</sub>=16MHz and F<sub>ADC</sub>=32MHz are given in tables 18-4-a and 18-4-b. The system designer must take into consideration both of these factors for optimal ADC operation.

**Table 15-4.  $R_S$  and  $F_{CONV}$  Values with Varying  $N_{SH}$  Values and  $F_{ADC} = 16$  MHz**

| $N_{SH}$ (Cycles)      | 4    | 8    | 16   | 32    | 64    | 128   | 256    |
|------------------------|------|------|------|-------|-------|-------|--------|
| $F_{CONV}$ (Ksps)      | 1000 | 800  | 571  | 364   | 211   | 114   | 60     |
| $R_S$ Max ( $\Omega$ ) | 500  | 3500 | 9500 | 21500 | 45500 | 93500 | 189500 |

**Table 15-5.  $R_S$  and  $F_{CONV}$  Values with Varying  $N_{SH}$  Values and  $F_{ADC} = 32$  MHz**

| $N_{SH}$ (Cycles)      | 4    | 8    | 16   | 32   | 64    | 128   | 256   |
|------------------------|------|------|------|------|-------|-------|-------|
| $F_{CONV}$ (Ksps)      | 2000 | 1600 | 1143 | 727  | 421   | 229   | 119   |
| $R_S$ Max ( $\Omega$ ) | 250  | 500  | 3500 | 9500 | 21500 | 45500 | 93500 |

### 15.3.2.6 Sample Phase Control

The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. If the converters are running at the same sample rate, they may be configured to start the conversions coincidentally or one ADC may be programmed to lag up to 15 clock cycles relative to the other ADC. The sample time can be delayed from the standard sampling time by programming the PHASE field in the **ADC Sample Phase Control (ADCSPC)** register. Figure 15-3 on page 1045 shows an example of various phase relationships.

**Figure 15-3. ADC Sample Phases**

This feature can be used to double the sampling rate of an input. Both ADC Module 0 and ADC Module 1 can be programmed to sample the same input. ADC module 0 can sample at the standard position (the PHASE field in the **ADCSPC** register is 0x0). ADC Module 1 can be configured to sample with a phase lag (PHASE is nonzero). For a sample rate of two million samples/second at 16MHz, the TSHn field of all of the sequencer samples of both ADCs must be programmed to 0x0 and the PHASE field of one of the ADC modules must be set to 0x8. The two modules can be synchronized using the GSYNC and SYNCWAIT bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. Software can then combine the results from the two modules to create a sample rate of two million samples/second at 16MHz as shown in Figure 15-4 on page 1046.

**Figure 15-4. Doubling the ADC Sample Rate**

Using the **ADCSPC** register, ADC0 and ADC1 may provide a number of interesting applications:

- Coincident continuous sampling of different signals. The sample sequence steps run coincidentally in both converters. In this situation, the TSHn of matching sample steps of both ADC module sequencers must be the same and the PHASE field must be 0x0 in both ADC module **ADCSPC** registers. The TSHn field is found in the **ADC Sample Sequence n Sample and Hold Time (ADCSSTSHn)** register.

- ADC Module 0, **ADCSPC** = 0x0, sampling AIN0

- ADC Module 1, **ADCSPC** = 0x0, sampling AIN1

**Note:** If two ADCs are configured to sample the same signal, a skew (phase lag) must be added to one of the ADC modules to prevent coincident sampling. Phase lag can be added by programming the PHASE field in the **ADCSPC** register.

- Skewed sampling of the same signal. The skew is determined by both the TSHn field in the **ADCSSTSHn** registers and the PHASE field in the **ADCSPC** register. For the fastest skewed sample rate, all TSHn fields must be programmed to 0x0. If TSHn=0x0 for all sequencers and the PHASE field of one ADC is 0x8, the configuration doubles the conversion bandwidth of a single input when software combines the results as shown in Figure 15-5 on page 1047.

- ADC Module 0, **ADCSPC** = 0x0, sampling AIN0

- ADC Module 1, **ADCSPC** = 0x8, sampling AIN0

Note that it is not required that the TSHn fields be the same in a skewed sample. If an application has varying analog input resistance, then TSHn and PHASE may vary according to operational requirements.

Figure 15-5. Skewed Sampling

### 15.3.2.7 Module Clocking

The ADC digital block is clocked by the system clock and the ADC analog block is clocked from a separate conversion clock (ADC Clock). The ADC clock frequency can be up to 32 MHz to generate a conversion rate of 2 Msps. A 16 MHz ADC clock provides a 1 Msps sampling rate. There are three sources of the ADC clock:

- Divided PLL VCO. The PLL VCO frequency can be configured to generate up to a 32-MHz clock for a conversion rate of 2 Msps. The CS field in the **ADCCC** register must be programmed to 0x0 to select the PLL VCO and the CLKDIV field is used to set the appropriate clock divisor for the desired frequency.
- 16 MHz PIOSC. Using the PIOSC provides a conversion rate near 1 Msps. To use the PIOSC to clock the ADC, first power up the PLL and then enable the PIOSC in the CS bit field in the **ADCCC** register, then disable the PLL.
- MOSC. The MOSC clock source must be 16 MHz for a 1 Msps conversion rate and 32 MHz for a 2 Msps conversion rate.

The system clock must be at the same frequency or higher than the ADC clock. All ADC modules share the same clock source to facilitate the synchronization of data samples between conversion units, the selection and programming of which is provided by ADC0's **ADCCC** register. The ADC modules do not run at different conversion rates.

### 15.3.2.8 Busy Status

The BUSY bit of the **ADCACTSS** register is used to indicate when the ADC is busy with a current conversion. When there are no triggers pending which may start a new conversion in the immediate cycle or next few cycles, the BUSY bit reads as 0. Software must read the status of the BUSY bit as clear before disabling the ADC clock by writing to the **Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC)** register.

### 15.3.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off, and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 1091). A single averaging circuit has been implemented, thus all input channels receive the same amount of averaging whether they are single-ended or differential.

Figure 15-6 shows an example in which the **ADCSAC** register is set to 0x2 for 4x hardware oversampling and the IE1 bit is set for the sample sequence, resulting in an interrupt after the second averaged value is stored in the FIFO.

**Figure 15-6. Sample Averaging Example**

### 15.3.4 Analog-to-Digital Converter

The Analog-to-Digital Converter (ADC) module uses a Successive Approximation Register (SAR) architecture to deliver a 12-bit, low-power, high-precision conversion value. The successive approximation uses a switched capacitor array to perform the dual functions of sampling and holding the signal as well as providing the 12-bit DAC operation.

Figure 15-7 shows the ADC input equivalency diagram; for parameter values, see “Analog-to-Digital Converter (ADC)” on page 1624.

Figure 15-7. ADC Input Equivalency

The ADC operates from both the 3.3-V analog and 1.2-V digital power supplies. The ADC clock can be configured to reduce power consumption when ADC conversions are not required (see “System Control” on page 233). The analog inputs are connected to the ADC through specially balanced input paths to minimize the distortion and cross-talk on the inputs. Detailed information on the ADC power supplies and analog inputs can be found in “Analog-to-Digital Converter (ADC)” on page 1624.

#### 15.3.4.1 Voltage Reference

The ADC uses internal signals VREFP and VREFN as references to produce a conversion value from the selected analog input. VREFP can be connected to either VREFA+ or VDDA and VREFN can be connected to either VREFA- or GNDA as configured by the VREF bit in the **ADC Control (ADCCTL)** register, as shown in Figure 15-8.

Figure 15-8. ADC Voltage Reference

The range of this conversion value is from 0x000 to 0xFFFF. In single-ended-input mode, the 0x000 value corresponds to the voltage level on VREFN; the 0xFFFF value corresponds to the voltage level on VREFP. This configuration results in a resolution that can be calculated using the following equation:

$$\text{mV per ADC code} = (\text{VREFP} - \text{VREFN}) / 4096$$

While the analog input pads can handle voltages beyond this range, the analog input voltages must remain within the limits prescribed by Table 26-44 on page 1624 to produce accurate results. The  $V_{\text{REFA+}}$  and  $V_{\text{REFA-}}$  specifications define the useful range for the external voltage references on VREFA+ and VREFA-, see Table 26-44 on page 1624. Care must be taken to supply a reference voltage of acceptable quality. Figure 15-9 on page 1050 shows the ADC conversion function of the analog inputs.

**Figure 15-9. ADC Conversion Result**

### 15.3.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the Dn bit in the **ADCSSCTL0n** register in a step's configuration nibble.

When a sequence step is configured for differential sampling, the input pair to sample must be configured in the **ADCSSMUXn** register. Differential pair 0 samples analog inputs 0 and 1; differential

pair 1 samples analog inputs 2 and 3; and so on (see Table 15-6 on page 1051). The ADC does not support other differential pairings such as analog input 0 with analog input 3.

**Table 15-6. Differential Sampling Pairs**

| Differential Pair | Analog Inputs |
|-------------------|---------------|
| 0                 | 0 and 1       |
| 1                 | 2 and 3       |
| 2                 | 4 and 5       |
| 3                 | 6 and 7       |
| 4                 | 8 and 9       |
| 5                 | 10 and 11     |
| 6                 | 12 and 13     |
| 7                 | 14 and 15     |
| 8                 | 16 and 17     |
| 9                 | 18 and 19     |
| 10                | 20 and 21     |
| 11                | 22 and 23     |

The voltage sampled in differential mode is the difference between the odd and even channels:

- Input Positive Voltage:  $V_{IN+} = V_{IN\_EVEN}$  (even channel)
- Input Negative Voltage:  $V_{IN-} = V_{IN\_ODD}$  (odd channel)

The input differential voltage is defined as:  $V_{IN_D} = V_{IN+} - V_{IN-}$ , therefore:

- If  $V_{IN_D} = 0$ , then the conversion result = 0x800
- If  $V_{IN_D} > 0$ , then the conversion result > 0x800 (range is 0x800–0xFFFF)
- If  $V_{IN_D} < 0$ , then the conversion result < 0x800 (range is 0–0x800)

When using differential sampling, the following definitions are relevant:

- Input Common Mode Voltage:  $V_{IN\_CM} = (V_{IN+} + V_{IN-}) / 2$
- Reference Positive Voltage:  $V_{REFP}$
- Reference Negative Voltage:  $V_{REFN}$
- Reference Differential Voltage:  $V_{REF_D} = V_{REFP} - V_{REFN}$
- Reference Common Mode Voltage:  $V_{REF\_CM} = (V_{REFP} + V_{REFN}) / 2$

The following conditions provide optimal results in differential mode:

- Both  $V_{IN\_EVEN}$  and  $V_{IN\_ODD}$  must be in the range of ( $V_{REFP}$  to  $V_{REFN}$ ) for a valid conversion result

- The maximum possible differential input swing, or the maximum differential range, is:  $-VREF_D$  to  $+VREF_D$ , so the maximum peak-to-peak input differential signal is  $(+VREF_D - -VREF_D) = 2 * VREF_D = 2 * (VREFP - VREFN)$
- In order to take advantage of the maximum possible differential input swing,  $VIN_{CM}$  should be very close to  $VREF_{CM}$ , see Table 26-44 on page 1624.

If  $VIN_{CM}$  is not equal to  $VREF_{CM}$ , the differential input signal may clip at either maximum or minimum voltage, because either single ended input can never be larger than  $VREFP$  or smaller than  $VREFN$ , and it is not possible to achieve full swing. Thus any difference in common mode between the input voltage and the reference voltage limits the differential dynamic range of the ADC.

Because the maximum peak-to-peak differential signal voltage is  $2 * (VREFP - VREFN)$ , the ADC codes are interpreted as:

$$\text{mV per ADC code} = (2 * (VREFP - VREFN)) / 4096$$

Figure 15-10 shows how the differential voltage,  $\Delta V$ , is represented in ADC codes.

**Figure 15-10. Differential Voltage Representation**

### 15.3.6 Internal Temperature Sensor

The temperature sensor serves two primary purposes: 1) to notify the system that internal temperature is too high or low for reliable operation and 2) to provide temperature measurements for calibration of the Hibernate module RTC trim value.

The temperature sensor does not have a separate enable, because it also contains the bandgap reference and must always be enabled. The reference is supplied to other analog modules; not just the ADC. In addition, the temperature sensor has a second power-down input in the 3.3 V domain which provides control by the Hibernation module.

The internal temperature sensor converts a temperature measurement into a voltage. This voltage value,  $V_{TSENS}$ , is given by the following equation (where TEMP is the temperature in °C):

$$V_{\text{TSENS}} = 2.7 - ((\text{TEMP} + 55) / 75)$$

This relation is shown in Figure 15-11 on page 1053.

**Figure 15-11. Internal Temperature Sensor Characteristic**

The temperature sensor reading can be sampled in a sample sequence by setting the TS<sub>n</sub> bit in the **ADCSSTLn** register. The sample and hold width should be configured for at least 16 ADC clocks using the **ADCSSTSHn** register. The temperature reading from the temperature sensor can also be given as a function of the ADC value. The following formula calculates temperature (TEMP in °C) based on the ADC reading (ADC<sub>CODE</sub>, given as an unsigned decimal number from 0 to 4095) and the maximum ADC voltage range (VREFP - VREFN):

$$\text{TEMP} = 147.5 - ((75 * (\text{VREFP} - \text{VREFN}) * \text{ADC}_{\text{CODE}}) / 4096)$$

### 15.3.7 Digital Comparator Unit

An ADC is commonly used to sample an external signal and to monitor its value to ensure that it remains in a given range. To automate this monitoring procedure and reduce the amount of processor overhead that is required, each module provides eight digital comparators.

Conversions from the ADC that are sent to the digital comparators are compared against the user programmable limits in the **ADC Digital Comparator Range (ADCDCMPn)** registers. The ADC can be configured to generate an interrupt depending on whether the ADC is operating within the low, mid or high-band region configured in the ADCDCMP<sub>n</sub> bit fields. The digital comparators four operational modes (Once, Always, Hysteresis Once, Hysteresis Always) can be additionally applied to the interrupt configuration.

#### 15.3.7.1 Output Functions

ADC conversions can either be stored in the ADC Sample Sequence FIFOs or compared using the digital comparator resources as defined by the SnDCOP bits in the **ADC Sample Sequence n Operation (ADCSOPn)** register. These selected ADC conversions are used by their respective

digital comparator to monitor the external signal. Each comparator has two possible output functions: processor interrupts and triggers.

Each function has its own state machine to track the monitored signal. Even though the interrupt and trigger functions can be enabled individually or both at the same time, the same conversion data is used by each function to determine if the right conditions have been met to assert the associated output.

### **Interrupts**

The digital comparator interrupt function is enabled by setting the CIE bit in the **ADC Digital Comparator Control (ADCDCCTLn)** register. This bit enables the interrupt function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, and the DCONSSx bit is set in the **ADCIM** register, an interrupt is sent to the interrupt controller.

**Note:** For a 1 to 2 Msps rate, as the system clock frequency approaches the ADC clock frequency, it is recommended that the application use the  $\mu$ DMA to store conversion data from the FIFO to memory before processing rather than an interrupt-driven single data read. Using the  $\mu$ DMA to store multiple samples before interrupting the processor amortizes interrupt overhead across multiple transfers and prevents loss of sample data.

**Note:** Only a single DCONSSn bit should be set at any given time. Setting more than one of these bits results in the INRDC bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

### **Triggers**

The digital comparator trigger function is enabled by setting the CTE bit in the **ADCDCCTLn** register. This bit enables the trigger function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, the corresponding digital comparator trigger to the PWM module is asserted.

## **15.3.7.2 Operational Modes**

Four operational modes are provided to support a broad range of applications and multiple possible signaling requirements: Always, Once, Hysteresis Always, and Hysteresis Once. The operational mode is selected using the CIM or CTM field in the **ADCDCCTLn** register.

### **Always Mode**

In the Always operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria. The result is a string of assertions on the interrupt or trigger while the conversions are within the appropriate range.

### **Once Mode**

In the Once operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria, and the previous ADC conversion value did not. The result is a single assertion of the interrupt or trigger when the conversions are within the appropriate range.

### **Hysteresis-Always Mode**

The Hysteresis-Always operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Always mode, the associated interrupt or trigger

is asserted in the following cases: 1) the ADC conversion value meets its comparison criteria or 2) a previous ADC conversion value has met the comparison criteria, and the hysteresis condition has not been cleared by entering the opposite region. The result is a string of assertions on the interrupt or trigger that continue until the opposite region is entered.

#### ***Hysteresis-Once Mode***

The Hysteresis-Once operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Once mode, the associated interrupt or trigger is asserted only when the ADC conversion value meets its comparison criteria, the hysteresis condition is clear, and the previous ADC conversion did not meet the comparison criteria. The result is a single assertion on the interrupt or trigger.

### **15.3.7.3 Function Ranges**

The two comparison values, COMP0 and COMP1, in the **ADC Digital Comparator Range (ADCDCMPn)** register effectively break the conversion area into three distinct regions. These regions are referred to as the low-band (less than COMP0), mid-band (greater than COMP0 but less than or equal to COMP1), and high-band (greater than or equal to COMP1) regions. COMP0 and COMP1 may be programmed to the same value, effectively creating two regions, but COMP1 must always be greater than or equal to the value of COMP0. A COMP1 value that is less than COMP0 generates unpredictable results.

#### ***Low-Band Operation***

To operate in the low-band region, the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x0. This setting causes interrupts or triggers to be generated in the low-band region as defined by the programmed operational mode. An example of the state of the interrupt/trigger signal in the low-band region for each of the operational modes is shown in Figure 15-12 on page 1056. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 15-12. Low-Band Operation (CIC=0x0 and/or CTC=0x0)

### Mid-Band Operation

To operate in the mid-band region, the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x1. This setting causes interrupts or triggers to be generated in the mid-band region according to the operation mode. Only the Always and Once operational modes are available in the mid-band region. An example of the state of the interrupt/trigger signal in the mid-band region for each of the allowed operational modes is shown in Figure 15-13 on page 1057. Note that a "0" in a column following the operational mode name (Always or Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 15-13. Mid-Band Operation (CIC=0x1 and/or CTC=0x1)

### High-Band Operation

To operate in the high-band region, the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x3. This setting causes interrupts or triggers to be generated in the high-band region according to the operation mode. An example of the state of the interrupt/trigger signal in the high-band region for each of the allowed operational modes is shown in Figure 15-14 on page 1058. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 15-14. High-Band Operation (CIC=0x3 and/or CTC=0x3)

## 15.4 Initialization and Configuration

### 15.4.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps: enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the sample sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock using the **RCGCADC** register (see page 386).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 373). To find out which GPIO ports to enable, refer to “Signal Description” on page 1040.
3. Set the GPIO AFSEL bits for the ADC input pins (see page 754). To determine which GPIOs to configure, see Table 25-4 on page 1556.
4. Configure the AINx signals to be analog inputs by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register (see page 765).
5. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 770) in the associated GPIO block.
6. If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority and Sample Sequencer 3 as the lowest priority.

## 15.4.2 Sample Sequencer Configuration

Configuration of the sample sequencers is slightly more complex than the module initialization because each sample sequencer is completely programmable.

The configuration for each sample sequencer should be as follows:

1. Ensure that the sample sequencer is disabled by clearing the corresponding ASENn bit in the **ADCACTSS** register. Programming of the sample sequencers is allowed without having them enabled. Disabling the sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
2. Configure the trigger event for the sample sequencer in the **ADCEMUX** register.
3. When using a PWM generator as the trigger source, use the **ADC Trigger Source Select (ADCTSSEL)** register to specify in which PWM module the generator is located. The default register reset selects PWM module 0 for all generators.
4. For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUXn** and **ADCSEMUXn** registers.
5. For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTLn** register. When programming the last nibble, ensure that the END bit is set. Failure to set the END bit causes unpredictable behavior.
6. If interrupts are to be used, set the corresponding MASK bit in the **ADCIM** register.
7. Enable the sample sequencer logic by setting the corresponding ASENn bit in the **ADCACTSS** register.

## 15.5 Register Map

Table 15-7 on page 1059 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to that ADC module's base address of:

- ADC0: 0x4003.8000
- ADC1: 0x4003.9000

Note that the ADC module clock must be enabled before the registers can be programmed (see page 386). There must be a delay of 3 system clocks after the ADC module clock is enabled before any ADC module registers are accessed.

**Table 15-7. ADC Register Map**

| Offset | Name     | Type | Reset       | Description                    | See page |
|--------|----------|------|-------------|--------------------------------|----------|

## **15.6 Register Descriptions**

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

**Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000**

This register controls the activation of the sample sequencers. Each sample sequencer can be enabled or disabled independently.

**ADC Active Sample Sequencer (ADCACTSS)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x000

Type RW, reset 0x0000.0000

**Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004**

This register shows the status of the raw interrupt signal of each sample sequencer. These bits may be polled by software to look for interrupt conditions without sending the interrupts to the interrupt controller.

**ADC Raw Interrupt Status (ADCRIS)**

**Register 3: ADC Interrupt Mask (ADCIM), offset 0x008**

This register controls whether the sample sequencer and digital comparator raw interrupt signals are sent to the interrupt controller. Each raw interrupt signal can be masked independently.

**Note:** For a 1 to 2 Msps rate, as the system clock frequency approaches the ADC clock frequency, it is recommended that the application use the  $\mu$ DMA to store conversion data from the FIFO to memory before processing rather than an interrupt-driven single data read. Using the  $\mu$ DMA to store multiple samples before interrupting the processor amortizes interrupt overhead across multiple transfers and prevents loss of sample data.

**Note:** Only a single DCONSSn bit should be set at any given time. Setting more than one of these bits results in the INRDC bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

**ADC Interrupt Mask (ADCIM)**

## Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing sample sequencer interrupt conditions and shows the status of interrupts generated by the sample sequencers and the digital comparators which have been sent to the interrupt controller. When read, each bit field is the logical AND of the respective INR and MASK bits. Sample sequencer interrupts are cleared by writing a 1 to the corresponding bit position. Digital comparator interrupts are cleared by writing a 1 to the appropriate bits in the **ADCDCISC** register. If software is polling the **ADCRIS** instead of generating interrupts, the sample sequence INRn bits are still cleared via the **ADCISC** register, even if the INn bit is not set.

### ADC Interrupt Status and Clear (ADCISC)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x00C

**Register 6: ADC Event Multiplexer Select (ADCEMUX), offset 0x014**

The **ADCEMUX** selects the event (trigger) that initiates sampling for each sample sequencer. Each sample sequencer can be configured with a unique trigger source.

**ADC Event Multiplexer Select (ADCEMUX)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x014

Type RW, reset 0x0000.0000

**Register 7: ADC Underflow Status (ADCUSTAT), offset 0x018**

This register indicates underflow conditions in the sample sequencer FIFOs. The corresponding underflow condition is cleared by writing a 1 to the relevant bit position.

**ADC Underflow Status (ADCUSTAT)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x018

Type RW1C, reset 0x0000.0000

**Register 8: ADC Trigger Source Select (ADCTSSEL), offset 0x01C**

If a PWM Generator *n* is selected as a trigger source through the EM*n* bit field in the **ADC Event Multiplexer Select (ADCEMUX)** register, the **ADCTSSEL** register is programmed to identify in which PWM module instance the generator creating the trigger is located. The register resets to 0x0000.0000, which selects PWM module 0 for all generators. Note that field PS3 selects the PWM module that maps to Generator 3; PS2 selects the PWM module that maps to Generator 2, and so on.

**ADC Trigger Source Select (ADCTSSEL)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x01C

Type RW, reset 0x0000.0000

**Register 9: ADC Sample Sequencer Priority (ADCSSPRI), offset 0x020**

This register sets the priority for each of the sample sequencers. Out of reset, Sequencer 0 has the highest priority, and Sequencer 3 has the lowest priority. When reconfiguring sequence priorities, each sequence must have a unique priority for the ADC to operate properly.

**ADC Sample Sequencer Priority (ADCSSPRI)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x020

Type RW, reset 0x0000.3210

## Register 10: ADC Sample Phase Control (ADCSPC), offset 0x024

The **ADC Sample Phase Control (ADCSPC)** register is used to insert a delay in ADC module sampling. This feature can be used with the SYNCWAIT and GSYNC bit in the **ADCPSSI** register to provide concurrent sampling of two different signals by two different ADC modules or skewed sampling of two ADC modules to increase the effective sampling rate. For concurrent sampling, the PHASE field of each ADC module must be the same and the sample and hold times (TSHn) for the matching sample steps of each ADC must be the same. For example, both ADC0 and ADC1 would program PHASE = 0x0 in the **ADCSPC** register and might both have the following configuration for their **ADCSSTSH0** register:

- TSH7=0x4
- TSH6=0x2
- TSH5=0x2
- TSH4=0x8
- TSH3=0x6
- TSH2=0x2
- TSH1=0x4
- TSH0=0x2

For skewed sampling with a consistent phase lag, the TSHn field in the **ADCSSTSHn** register must be the same for all sample steps of an ADC and for both ADC Modules. The desired lag can be calculated by adding the sample and hold time (TSHn) to the twelve clock conversion time to determine the total number of clocks in a sample period. For example to create a 180.0° phase lag, the PHASE of the lagging ADC is calculated as:

$\text{PHASE} = (\text{TSHn} + 12)/2$ , where TSHn is in ADC\_Clocks

For situations where a predictable phase lag is not required, sample and hold times (TSHn) of ADC modules can vary.

**Note:** Care should be taken when the PHASE field is non-zero, as the resulting delay in sampling the AINx input may result in undesirable system consequences. The time from ADC trigger to sample is increased and could make the response time longer than anticipated. The added latency could have ramifications in the system design. Designers should carefully consider the impact of this delay.

**Register 11: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028**

This register provides a mechanism for application software to initiate sampling in the sample sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

This register also provides a means to configure and then initiate concurrent sampling on all ADC modules. To do this, the first ADC module should be configured. The **ADCPSSI** register for that module should then be written. The appropriate SS bits should be set along with the SYNCWAIT bit. Additional ADC modules should then be configured following the same procedure. Once the final ADC module is configured, its **ADCPSSI** register should be written with the appropriate SS bits set along with the GSYNC bit. All of the ADC modules then begin concurrent sampling according to their configuration.

**ADC Processor Sample Sequence Initiate (ADCPSSI)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x028

Type RW, reset -

**Register 12: ADC Sample Averaging Control (ADCSAC), offset 0x030**

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from  $2^{AVG}$  consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG=7 provides unpredictable results.

**ADC Sample Averaging Control (ADCSAC)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x030

Type RW, reset 0x0000.0000

## Register 13: ADC Digital Comparator Interrupt Status and Clear (ADCDCISC), offset 0x034

This register provides status and acknowledgement of digital comparator interrupts. One bit is provided for each comparator.

### ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x034

Type RW1C, reset 0x0000.0000

**Register 14: ADC Control (ADCCTL), offset 0x038**

This register configures the voltage reference. The voltage references for the conversion can be VREFA+ and VREFA- or VDDA and GNDA. Note that values set in this register apply to all ADC modules, it is not possible to set one module to use internal references and another to use external references.

**ADC Control (ADCCTL)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x038

Type RW, reset 0x0000.0000

## Register 15: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register, along with the **ADCSSMUX0** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. If the corresponding EMUXn bit in the **ADCSSMUX0** register is set, the MUXn field in this register selects from AIN[23:16]. When the corresponding EMUXn bit is clear, the MUXn field selects from AIN[15:0]. This register is 32 bits wide and contains information for eight possible samples.

**Note:** Channels AIN[31:24] do not exist on this microcontroller. Configuring MUXn to be 0x8-0xF when the corresponding EMUXn bit is set results in undefined behavior.

**Register 16: ADC Sample Sequence Control 0 (ADCSSCTL0), offset 0x044**

This register contains the configuration information for each sample for a sequence executed with a sample sequencer. When configuring a sample sequence, the END bit must be set for the final sample, whether it be after the first sample, eighth sample, or any sample in between. This register is 32 bits wide and contains information for eight possible samples.

**Register 17: ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0), offset 0x048**

**Register 18: ADC Sample Sequence Result FIFO 1 (ADCSSFIFO1), offset 0x068**

**Register 19: ADC Sample Sequence Result FIFO 2 (ADCSSFIFO2), offset 0x088**

**Register 20: ADC Sample Sequence Result FIFO 3 (ADCSSFIFO3), offset 0x0A8**

**Important:** This register is read-sensitive. See the register description for details.

This register contains the conversion results for samples collected with the sample sequencer (the **ADCSSFIFO0** register is used for Sample Sequencer 0, **ADCSSFIFO1** for Sequencer 1, **ADCSSFIFO2** for Sequencer 2, and **ADCSSFIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCOSTAT** and **ADCUSTAT** registers.

**Register 21: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C**

**Register 22: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C**

**Register 23: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C**

**Register 24: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC**

This register provides a window into the sample sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO with the head and tail pointers both pointing to index 0. The **ADCSSFSTAT0** register provides status on FIFO0, which has 8 entries; **ADCSSFSTAT1** on FIFO1, which has 4 entries; **ADCSSFSTAT2** on FIFO2, which has 4 entries; and **ADCSSFSTAT3** on FIFO3 which has a single entry.

## Register 26: ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0), offset 0x054

This register determines which digital comparator receives the sample from the given conversion on Sample Sequence 0, if the corresponding SnDCOP bit in the **ADCSSOP0** register is set.

### ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x054  
 Type RW, reset 0x0000.0000

## Register 27: ADC Sample Sequence Extended Input Multiplexer Select 0 (ADCSEMUX0), offset 0x058

This register, along with the **ADCSSMUX0** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. If a bit in this register is set, the corresponding MUXn field in the **ADCSSMUX0** register selects from AIN[23:16]. When a bit in this register is clear, the corresponding MUXn field selects from AIN[15:0]. This register is 32 bits wide and contains information for eight possible samples.

Note that this register is not used when the differential channel designation is used (the Dn bit is set in the **ADCSSCTL0** register) because the **ADCSSMUX0** register can select all the available pairs.

### ADC Sample Sequence Extended Input Multiplexer Select 0 (ADCSEMUX0)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x058  
 Type RW, reset 0x0000.0000

## Register 28: ADC Sample Sequence 0 Sample and Hold Time (ADCSSTSH0), offset 0x05C

This register controls the sample period size for each sample of sequencer 0. Each sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 15-3 on page 1044.

**Note:** If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks (TSHn = 0x4).

**Table 15-8. Sample and Hold Width in ADC Clocks**

**Register 29: ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1), offset 0x060****Register 30: ADC Sample Sequence Input Multiplexer Select 2 (ADCSSMUX2), offset 0x080**

This register, along with the **ADCSSMUX1** or **ADCSSMUX2** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 1 or 2. If the corresponding EMUXn bit in the **ADCSSMUX1** or **ADCSSMUX2** register is set, the MUXn field in this register selects from AIN[23:16]. When the corresponding EMUXn bit is clear, the MUXn field selects from AIN[15:0]. These registers are 16 bits wide and contain information for four possible samples. See the **ADCSSMUX0** register on page 1095 for detailed bit descriptions. The **ADCSSMUX1** register affects Sample Sequencer 1 and the **ADCSSMUX2** register affects Sample Sequencer 2.

**Note:** Channels AIN[31:24] do not exist on this microcontroller. Configuring MUXn to be 0x8-0xF when the corresponding EMUXn bit is set results in undefined behavior.

**Register 31: ADC Sample Sequence Control 1 (ADCSSCTL1), offset 0x064****Register 32: ADC Sample Sequence Control 2 (ADCSSCTL2), offset 0x084**

These registers contain the configuration information for each sample for a sequence executed with Sample Sequencer 1 or 2. When configuring a sample sequence, the END bit must be set for the final sample, whether it be after the first sample, fourth sample, or any sample in between. These registers are 16-bits wide and contain information for four possible samples. See the **ADCSSCTL0** register on page 1097 for detailed bit descriptions. The **ADCSSCTL1** register configures Sample Sequencer 1 and the **ADCSSCTL2** register configures Sample Sequencer 2.

**Register 33: ADC Sample Sequence 1 Operation (ADCSSOP1), offset 0x070****Register 34: ADC Sample Sequence 2 Operation (ADCSSOP2), offset 0x090**

This register determines whether the sample from the given conversion on Sample Sequence n is saved in the Sample Sequence n FIFO or sent to the digital comparator unit. The **ADCSSOP1** register controls Sample Sequencer 1 and the **ADCSSOP2** register controls Sample Sequencer 2.

**ADC Sample Sequence n Operation (ADCSSOPn)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x070

Type RW, reset 0x0000.0000

**Register 35: ADC Sample Sequence 1 Digital Comparator Select (ADCSSDC1), offset 0x074****Register 36: ADC Sample Sequence 2 Digital Comparator Select (ADCSSDC2), offset 0x094**

These registers determine which digital comparator receives the sample from the given conversion on Sample Sequence n if the corresponding SnDCOP bit in the **ADCSSOPn** register is set. The **ADCSSDC1** register controls the selection for Sample Sequencer 1 and the **ADCSSDC2** register controls the selection for Sample Sequencer 2.

**ADC Sample Sequence n Digital Comparator Select (ADCSSDCn)**

### Register 37: ADC Sample Sequence Extended Input Multiplexer Select 1 (ADCSEMUX1), offset 0x078

### Register 38: ADC Sample Sequence Extended Input Multiplexer Select 2 (ADCSEMUX2), offset 0x098

This register, along with the **ADCSSMUX1** or **ADCSSMUX2** register, defines the analog input configuration for each sample in a sequence executed with either Sample Sequencer 1 or 2. If a bit in this register is set, the corresponding MUXn field in the **ADCSSMUX1** or **ADCSSMUX2** register selects from AIN[23:16]. When a bit in this register is clear, the corresponding MUXn field selects from AIN[15:0]. This register is 16 bits wide and contains information for four possible samples. The **ADCSEMUX1** register controls Sample Sequencer 1 and the **ADCSEMUX2** register controls Sample Sequencer 2.

Note that this register is not used when the differential channel designation is used (the Dn bit is set in the **ADCSSCTL1** or **ADCSSCTL2** register) because the **ADCSSMUX1** or **ADCSSMUX2** register can select all the available pairs.

#### ADC Sample Sequence Extended Input Multiplexer Select n (ADCSEMUXn)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x078  
 Type RW, reset 0x0000.0000

**Register 39: ADC Sample Sequence 1 Sample and Hold Time (ADCSSTSH1), offset 0x07C****Register 40: ADC Sample Sequence 2 Sample and Hold Time (ADCSSTSH2), offset 0x09C**

These registers control the sample period size for each sample step of sequencer 1 and sequencer 2. Each sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 15-3 on page 1044.

**Note:** If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks ( $TSH_n = 0x4$ ).

**Table 15-9. Sample and Hold Width in ADC Clocks**

## Register 41: ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3), offset 0x0A0

This register, along with the **ADCSEMUX3** register, defines the analog input configuration for the sample in a sequence executed with Sample Sequencer 3. If the EMUX0 bit in the **ADCSEMUX3** register is set, the MUX0 field in this register selects from AIN[23:16]. When the EMUX0 bit is clear, the MUX0 field selects from AIN[15:0]. This register is four bits wide and contains information for one possible sample. See the **ADCSSMUX0** register on page 1095 for detailed bit descriptions.

|           |      |      |       | Value Description                                                                                                                                                      |
|           |      |      |       | 0 The analog inputs are not differentially sampled.                                                                                                                    |
|           |      |      |       | 1 The analog input is differentially sampled. The corresponding <b>ADCSSMUXn</b> nibble must be set to the pair number "i", where the paired inputs are "2i and 2i+1". |
|           |      |      |       | Because the temperature sensor does not have a differential option, this bit must not be set when the TS0 bit is set.                                                  |

**Register 43: ADC Sample Sequence 3 Operation (ADCSSOP3), offset 0x0B0**

This register determines whether the sample from the given conversion on Sample Sequence 3 is saved in the Sample Sequence 3 FIFO or sent to the digital comparator unit.

**ADC Sample Sequence 3 Operation (ADCSSOP3)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x0B0

Type RW, reset 0x0000.0000

**Value Description**

- |   |                                                                                                                                                            |
|---|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | The sample is saved in Sample Sequence FIFO3.                                                                                                              |
| 1 | The sample is sent to the digital comparator unit specified by the S0DCSEL bit in the <b>ADCSSDC03</b> register, and the value is not written to the FIFO. |

## Register 44: ADC Sample Sequence 3 Digital Comparator Select (ADCSSDC3), offset 0x0B4

This register determines which digital comparator receives the sample from the given conversion on Sample Sequence 3 if the corresponding SnDCOP bit in the **ADCSSOP3** register is set.

Register 45: ADC Sample Sequence Extended Input Multiplexer Select 3 (ADCSEMUX3), offset 0x0B8

This register, along with the **ADCSSMUX3** register, defines the analog input configuration for the sample in a sequence executed with Sample Sequencer 3. If EMUX0 is set, the MUX0 field in the **ADCSSMUX3** register selects from AIN[23:16]. When EMUX0 is clear, the MUX0 field selects from AIN[15:0]. This register is 1 bit wide and contains information for one possible sample.

Note that this register is not used when the differential channel designation is used (the Dn bit is set in the **ADCSSCTL3** register) because the **ADCSSMUX3** register can select all the available pairs.

ADC Sample Sequence Extended Input Multiplexer Select 3 (ADCSEMUX3)

For example, if the MUX0 field is 0x0, AIN16 is selected.</div> |

## Register 46: ADC Sample Sequence 3 Sample and Hold Time (ADCSSTSH3), offset 0x0BC

This register controls the sample period size for the sample in sequencer 3. The sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 15-3 on page 1044

**Note:** If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks (TSHn = 0x4).

**Table 15-10. Sample and Hold Width in ADC Clocks**

| TSHn Encoding | N <sub>SH</sub> |
|---------------|-----------------|

## Register 47: ADC Digital Comparator Reset Initial Conditions (ADCDCRIC), offset 0xD00

This register provides the ability to reset any of the digital comparator interrupt or trigger functions back to their initial conditions. Resetting these functions ensures that the data that is being used by the interrupt and trigger functions in the digital comparator unit is not stale.

### ADC Digital Comparator Reset Initial Conditions (ADCDCRIC)

ADC0 base: 0x4003.8000

| 1                 | Enables the trigger function state machine. The ADC conversion data is used to determine if a trigger should be generated according to the programming of the CTC and CTM fields. |      |          |                                                                                                                                                                                               |

No additional interrupts are generated until the hysteresis condition is cleared by entering the opposite operational region.<br/>Note that the hysteresis modes are only defined for CTC encodings of 0x0 and 0x3.</p> |

**Register 56: ADC Digital Comparator Range 0 (ADCDCCMP0), offset 0xE40**

**Register 57: ADC Digital Comparator Range 1 (ADCDCCMP1), offset 0xE44**

**Register 58: ADC Digital Comparator Range 2 (ADCDCCMP2), offset 0xE48**

**Register 59: ADC Digital Comparator Range 3 (ADCDCCMP3), offset 0xE4C**

**Register 60: ADC Digital Comparator Range 4 (ADCDCCMP4), offset 0xE50**

**Register 61: ADC Digital Comparator Range 5 (ADCDCCMP5), offset 0xE54**

**Register 62: ADC Digital Comparator Range 6 (ADCDCCMP6), offset 0xE58**

**Register 63: ADC Digital Comparator Range 7 (ADCDCCMP7), offset 0xE5C**

This register defines the comparison values that are used to determine if the ADC conversion data falls in the appropriate operating region.

**Note:** The value in the COMP1 field must be greater than or equal to the value in the COMP0 field or unexpected results can occur.

#### ADC Digital Comparator Range n (ADCDCCMPn)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xE40

Type RW, reset 0x0000.0000

**Register 65: ADC Peripheral Configuration (ADCPC), offset 0xFC4**

The **ADCPC** register provides information regarding the configuration of the peripheral.

**ADC Peripheral Configuration (ADCPC)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xFC4

Type RW, reset 0x0000.0007

**Register 66: ADC Clock Configuration (ADCCC), offset 0xFC8**

The **ADCCC** register controls the clock source for the ADC module.

**ADC Clock Configuration (ADCCC)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xFC8

Type RW, reset 0x0000.0001

## 16 Universal Asynchronous Receivers/Transmitters (UARTs)

The TM4C1290NCZAD controller includes eight Universal Asynchronous Receiver/Transmitter (UART) with the following features:

- Programmable baud-rate generator allowing speeds up to 7.5 Mbps for regular speed (divide by 16) and 15 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem functionality available on the following UARTs:
  - UART0 (modem flow control and modem status)
  - UART1 (modem flow control and modem status)
  - UART2 (modem flow control)
  - UART3 (modem flow control)
  - UART4 (modem flow control)
- EIA-485 9-bit support

- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
  - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock

## 16.1 Block Diagram

Figure 16-1. UART Module Block Diagram

## 16.2 Signal Description

The following table lists the external signals of the UART module and describes the function of each. The UART signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin

placements for these UART signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 754) should be set to choose the UART function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 771) to assign the UART signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 723.

## 16.3 Functional Description

Each TM4C1290NCZAD UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control (UARTCTL)** register (see page 1175). Transmit and receive are both enabled out of reset. Before any

control registers are programmed, the UART must be disabled by clearing the UARTEN bit in **UARTCTL**. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART module also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the **UARTCTL** register.

### 16.3.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 16-2 on page 1151 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

**Figure 16-2. UART Character Frame**

### 16.3.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divisor allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 1171) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 1172). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = \text{UARTSysClk} / (\text{ClkDiv} * \text{Baud Rate})$$

where *UARTSysClk* is the system clock connected to the UART, and *ClkDiv* is either 16 (if HSE in **UARTCTL** is clear) or 8 (if HSE is set). By default, this will be the main system clock described in “Clock Control” on page 225. Alternatively, the UART may be clocked from the internal precision oscillator (PIOSC), independent of the system clock selection. This will allow the UART clock to be programmed independently of the system clock PLL settings. See the **UARTCC** register for more details.

The 6-bit fractional number (that is to be loaded into the DIVFRAC bit field in the **UARTFBRD** register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8x or 16x the baud-rate (referred to as Baud8 and Baud16, depending on the setting of the HSE bit (bit 5) in **UARTCTL**). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during

receive operations. Note that the state of the HSE bit has no effect on clock generation in ISO 7816 smart card mode (when the SMART bit in the **UARTCTL** register is set).

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 1173), the **UARTIBRD** and **UARTFBRD** registers form an internal 30-bit register. This internal register is only updated when a write operation to **UARTLCRH** is performed, so any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- **UARTIBRD** write, **UARTFBRD** write, and **UARTLCRH** write
- **UARTFBRD** write, **UARTIBRD** write, and **UARTLCRH** write
- **UARTIBRD** write and **UARTLCRH** write
- **UARTFBRD** write and **UARTLCRH** write

### 16.3.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the **UARTLCRH** register. Data continues to be transmitted until there is no data left in the transmit FIFO. The BUSY bit in the **UART Flag (UARTFR)** register (see page 1167) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The BUSY bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the UnRx signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of Baud16 or fourth cycle of Baud8 depending on the setting of the HSE bit (bit 5) in **UARTCTL** (described in “Transmit/Receive Logic” on page 1151).

The start bit is valid and recognized if the UnRx signal is still low on the eighth cycle of Baud16 (HSE clear) or the fourth cycle of Baud 8 (HSE set), otherwise it is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of Baud16 or 8th cycle of Baud8 (that is, one bit period later) according to the programmed length of the data characters and value of the HSE bit in **UARTCTL**. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the **UARTLCRH** register.

Lastly, a valid stop bit is confirmed if the UnRx signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

### 16.3.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the UnTx and UnRx pins for the SIR protocol. These signals should be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before

data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of  $\frac{3}{16}$ th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW and driving the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal ( $1.63\ \mu\text{s}$ , assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCTL** register (see page 1175).

Whether the device is in normal or low-power IrDA mode, a start bit is deemed valid if the decoder is still Low, one period of IrLPBaud16 after the Low was first detected. This enables a normal-mode UART to receive data from a low-power mode UART that can transmit pulses as small as  $1.41\ \mu\text{s}$ . Thus, for both low-power and normal mode operation, the ILPDVSR field in the **UARTILPR** register must be programmed such that  $1.42\ \text{MHz} < F_{\text{IrLPBaud16}} < 2.12\ \text{MHz}$ , resulting in a low-power pulse duration of  $1.41\text{--}2.11\ \mu\text{s}$  (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than  $1.4\ \mu\text{s}$  are accepted as valid pulses.

Figure 16-3 on page 1153 shows the UART transmit and receive signals, with and without IrDA modulation.

**Figure 16-3. IrDA Data Modulation**

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10-ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

### 16.3.5 ISO 7816 Support

The UART offers basic support to allow communication with an ISO 7816 smartcard. When bit 3 (SMART) of the **UARTCTL** register is set, the UnTx signal is used as a bit clock, and the UnRx signal is used as the half-duplex communication line connected to the smartcard. A GPIO signal can be used to generate the reset signal to the smartcard. The remaining smartcard signals should be provided by the system design. The maximum clock rate in this mode is system clock / 16.

When using ISO 7816 mode, the **UARTLCRH** register must be set to transmit 8-bit words (WLEN bits 6:5 configured to 0x3) with EVEN parity (PEN set and EPS set). In this mode, the UART automatically uses 2 stop bits, and the STP2 bit of the **UARTLCRH** register is ignored.

If a parity error is detected during transmission, UnRx is pulled Low during the second stop bit. In this case, the UART aborts the transmission, flushes the transmit FIFO and discards any data it contains, and raises a parity error interrupt, allowing software to detect the problem and initiate retransmission of the affected data. Note that the UART does not support automatic retransmission in this case.

### 16.3.6 Modem Handshake Support

This section describes how to configure and use the modem flow control and status signals for a UART when connected as a DTE (data terminal equipment) or as a DCE (data communications equipment). In general, a modem is a DCE and a computing device that connects to a modem is the DTE.

#### 16.3.6.1 Signaling

The status signals provided by a UART differ based on whether the UART is used as a DTE or DCE. When used as a DTE, the modem flow control and status signals are defined as:

- $\overline{\text{UnCTS}}$  is Clear To Send
- $\overline{\text{UnDSR}}$  is Data Set Ready
- $\overline{\text{UnDCD}}$  is Data Carrier Detect
- $\overline{\text{UnRI}}$  is Ring Indicator
- $\overline{\text{UnRTS}}$  is Request To Send
- $\overline{\text{UnDTR}}$  is Data Terminal Ready

When used as a DCE, the modem flow control and status signals are defined as:

- $\overline{\text{UnCTS}}$  is Request To Send
- $\overline{\text{UnDSR}}$  is Data Terminal Ready
- $\overline{\text{UnRTS}}$  is Clear To Send
- $\overline{\text{UnDTR}}$  is Data Set Ready

Note that the support for DCE functions Data Carrier Detect and Ring Indicator are not provided. If these signals are required, their function can be emulated by using a general-purpose I/O signal and providing software support.

### 16.3.6.2 Flow Control

Flow control can be accomplished by either hardware or software. The following sections describe the different methods.

#### **Hardware Flow Control (RTS/CTS)**

Hardware flow control between two devices is accomplished by connecting the  $\overline{\text{RTS}}$  output to the Clear-To-Send input on the receiving device, and connecting the Request-To-Send output on the receiving device to the  $\overline{\text{CTS}}$  input.

The  $\overline{\text{CTS}}$  input controls the transmitter. The transmitter may only transmit data when the  $\overline{\text{CTS}}$  input is asserted. The  $\overline{\text{RTS}}$  output signal indicates the state of the receive FIFO.  $\overline{\text{CTS}}$  remains asserted until the preprogrammed watermark level is reached, indicating that the Receive FIFO has no space to store additional characters.

The **UARTCTL** register bits 15 (CTSEN) and 14 (RTSEN) specify the flow control mode as shown in Table 16-2 on page 1155.

**Table 16-2. Flow Control Mode**

| CTSEN | RTSEN | Description                            |
|-------|-------|----------------------------------------|
| 1     | 1     | RTS and CTS flow control enabled       |
| 1     | 0     | Only CTS flow control enabled          |
| 0     | 1     | Only RTS flow control enabled          |
| 0     | 0     | Both RTS and CTS flow control disabled |

Note that when RTSEN is 1, software cannot modify the  $\overline{\text{RTS}}$  output value through the **UARTCTL** register Request to Send (RTS) bit, and the status of the RTS bit should be ignored.

#### **Software Flow Control (Modem Status Interrupts)**

Software flow control between two devices is accomplished by using interrupts to indicate the status of the UART. Interrupts may be generated for the  $\overline{\text{DSR}}$ ,  $\overline{\text{DCD}}$ ,  $\overline{\text{CTS}}$ , and  $\overline{\text{RI}}$  signals using bits 3:0 of the **UARTIM** register, respectively. The raw and masked interrupt status may be checked using the **UARTRIS** and **UARTMIS** register. These interrupts may be cleared using the **UARTICR** register.

### 16.3.7 9-Bit UART Mode

The UART provides a 9-bit mode that is enabled with the 9BITEN bit in the **UART9BITADDR** register. This feature is useful in a multi-drop configuration of the UART where a single master connected to multiple slaves can communicate with a particular slave through its address or set of addresses along with a qualifier for an address byte. All the slaves check for the address qualifier in the place of the parity bit and, if set, then compare the byte received with the preprogrammed address. If the address matches, then it receives or sends further data. If the address does not match, it drops the address byte and any subsequent data bytes. If the UART is in 9-bit mode, then the receiver operates with no parity mode. The address can be predefined to match with the received byte and it can be configured with the **UART9BITADDR** register. The matching can be extended to a set of addresses using the address mask in the **UART9BITAMASK** register. By default, the **UART9BITAMASK** is 0xFF, meaning that only the specified address is matched.

When not finding a match, the rest of the data bytes with the 9th bit cleared are dropped. If a match is found, then an interrupt is generated to the NVIC for further action. The subsequent data bytes with the cleared 9th bit are stored in the FIFO. Software can mask this interrupt in case  $\mu$ DMA and/or FIFO operations are enabled for this instance and processor intervention is not required. All the

send transactions with 9-bit mode are data bytes and the 9th bit is cleared. Software can override the 9th bit to be set (to indicate address) by overriding the parity settings to sticky parity with odd parity enabled for a particular byte. To match the transmission time with correct parity settings, the address byte can be transmitted as a single then a burst transfer. The Transmit FIFO does not hold the address/data bit, hence software should take care of enabling the address bit appropriately.

### 16.3.8 FIFO Operation

The UART has two 16x8 FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 1162). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the FEN bit in **UARTLCRH** (page 1173).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 1167) and the **UART Receive Status (UARTRSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits), and the **UARTRSR** register shows overrun status via the OE bit. If the FIFOs are disabled, the empty and full flags are set according to the status of the 1-byte-deep holding registers.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 1179). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , and  $\frac{7}{8}$ . For example, if the  $\frac{1}{4}$  option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the  $\frac{1}{2}$  mark.

### 16.3.9 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error
- Parity Error
- Framing Error
- Receive Timeout
- Transmit (when condition defined in the TXIFLSEL bit in the **UARTIFLS** register is met, or if the EOT bit in **UARTCTL** is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the RXIFLSEL bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 1189).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 1181) by setting the corresponding IM bits. If interrupts are not used, the raw interrupt status is visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 1185).

**Note:** For receive timeout, the RTIM bit in the **UARTIM** register must be set to see the RTMIS and RTRIS status in the **UARTMIS** and **UARTRIS** registers.

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by writing a 1 to the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 1193).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period when the HSE bit is clear or over a 64-bit period when the HSE bit is set. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

The receive interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the RXRIS bit is set. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the trigger level, or by clearing the interrupt by writing a 1 to the RXIC bit.
- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the RXRIS bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, or by clearing the interrupt by writing a 1 to the RXIC bit.

The transmit interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the TXRIS bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts will be generated. The transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger level, or by clearing the interrupt by writing a 1 to the TXIC bit.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the TXRIS bit is set. It is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt by writing a 1 to the TXIC bit.

### 16.3.10 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the LBE bit in the **UARTCTL** register (see page 1175). In loopback mode, data transmitted on the UnTx output is received on the UnRx input. Note that the LBE bit should be set before the UART is enabled.

### 16.3.11 DMA Operation

The UART provides an interface to the  $\mu$ DMA controller with separate channels for transmit and receive. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the **UARTIFLS** register. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending on how the DMA channel is configured.

To enable DMA operation for the receive channel, set the RXDMAE bit of the **DMA Control (UARTDMACTL)** register. To enable DMA operation for the transmit channel, set the TXDMAE bit of the **UARTDMACTL** register. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the DMAERR bit of the **UARTDMACR** register is set and a receive error occurs, the DMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

When the  $\mu$ DMA is finished transferring data to the TX FIFO or from the RX FIFO, a dma\_done signal is sent to the UART to indicate completion. The dma\_done status is indicated through the DMATXRIS and DMARXIS bits of the **UARTRIS** register. An interrupt can be generated from these status bits by setting the DMATXIM and/or DMARXIM bits in the **UARTIM** register.

**Note:** The DMATXRIS bit can be used to indicate the  $\mu$ DMA's completion of data transfer to the TX FIFO. To indicate transfer completion from the UART's serializer, the end-of-transmission bit (EOT bit) should be enabled in the **UARTCTL** register. An interrupt can be generated on an end-of-transmission completion by setting the EOTIM bit of the **UARTIM** register.

See "Micro Direct Memory Access ( $\mu$ DMA)" on page 659 for more details about programming the  $\mu$ DMA controller.

## 16.4 Initialization and Configuration

To enable and initialize the UART, the following steps are necessary:

1. Enable the UART module using the **RCGCUART** register (see page 379).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 373). To find out which GPIO port to enable, refer to Table 25-5 on page 1569.
3. Set the GPIO AFSEL bits for the appropriate pins (see page 754). To determine which GPIOs to configure, see Table 25-4 on page 1556.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected (see page 756 and page 764).
5. Configure the PMCN fields in the **GPIOCTL** register to assign the UART signals to the appropriate pins (see page 771 and Table 25-5 on page 1569).

To use the UART, the peripheral clock must be enabled by setting the appropriate bit in the **RCGCUART** register (page 379). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (page 373) in the System Control module. To find out which GPIO port to enable, refer to Table 25-5 on page 1569.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz, and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity
- FIFOs disabled

- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), because the **UARTIBRD** and **UARTFBRD** registers must be written before the **UARTLCRH** register. Using the equation described in “Baud-Rate Generation” on page 1151, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the **DIVINT** field of the **UARTIBRD** register (see page 1171) should be set to 10 decimal or 0xA. The value to be loaded into the **UARTFBRD** register (see page 1172) is calculated by the equation:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the **UARTEN** bit in the **UARTCTL** register.
2. Write the integer portion of the BRD to the **UARTIBRD** register.
3. Write the fractional portion of the BRD to the **UARTFBRD** register.
4. Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
5. Configure the UART clock source by writing to the **UARTCC** register.
6. Optionally, configure the  $\mu$ DMA channel (see “Micro Direct Memory Access ( $\mu$ DMA)” on page 659) and enable the DMA option(s) in the **UARTDMACTL** register.
7. Enable the UART by setting the **UARTEN** bit in the **UARTCTL** register.

## 16.5 Register Map

Table 16-3 on page 1160 lists the UART registers. The offset listed is a hexadecimal increment to the register's address, relative to that UART's base address:

- UART0: 0x4000.C000
- UART1: 0x4000.D000
- UART2: 0x4000.E000
- UART3: 0x4000.F000
- UART4: 0x4001.0000
- UART5: 0x4001.1000
- UART6: 0x4001.2000
- UART7: 0x4001.3000

The UART module clock must be enabled before the registers can be programmed (see page 379). There must be a delay of 3 system clocks after the UART module clock is enabled before any UART module registers are accessed.

The UART must be disabled (see the **UARTEN** bit in the **UARTCTL** register on page 1175) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)

- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

**Table 16-3. UART Register Map**

| Offset | Name          | Type | Reset       | Description                       | See page |
|--------|---------------|------|-------------|-----------------------------------|----------|

## 16.6 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

**Register 1: UART Data (UARTDR), offset 0x000**

**Important:** This register is read-sensitive. See the register description for details.

This register is the data register (the interface to the FIFOs).

For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

## Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared on reset.

#### Value Description

|   |                                                                       |
|---|-----------------------------------------------------------------------|
| 0 | No data has been lost due to a FIFO overrun.                          |
| 1 | New data was received when the FIFO was full, resulting in data loss. |

This bit is cleared by a write to **UARTECR**.

The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO.

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|-------------|
|-----------|------|------|-------|-------------|

|   |    |    |   |                  |
|---|----|----|---|------------------|
| 2 | BE | RO | 0 | UART Break Error |
|---|----|----|---|------------------|

| Value | Description |
|-------|-------------|
|-------|-------------|

|   |                                 |
|---|---------------------------------|
| 0 | No break condition has occurred |
|---|---------------------------------|

|   |                                                                                                                                                                                         |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits). |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

This bit is cleared to 0 by a write to **UARTECR**.

In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received.

|   |    |    |   |                   |
|---|----|----|---|-------------------|
| 1 | PE | RO | 0 | UART Parity Error |
|---|----|----|---|-------------------|

| Value | Description |
|-------|-------------|
|-------|-------------|

|   |                              |
|---|------------------------------|
| 0 | No parity error has occurred |
|---|------------------------------|

|   |                                                                                                                              |
|---|------------------------------------------------------------------------------------------------------------------------------|
| 1 | The parity of the received data character does not match the parity defined by bits 2 and 7 of the <b>UARTLCRH</b> register. |
|---|------------------------------------------------------------------------------------------------------------------------------|

This bit is cleared to 0 by a write to **UARTECR**.

|   |    |    |   |                    |
|---|----|----|---|--------------------|
| 0 | FE | RO | 0 | UART Framing Error |
|---|----|----|---|--------------------|

| Value | Description |
|-------|-------------|
|-------|-------------|

|   |                               |
|---|-------------------------------|
| 0 | No framing error has occurred |
|---|-------------------------------|

|   |                                                                                |
|---|--------------------------------------------------------------------------------|
| 1 | The received character does not have a valid stop bit (a valid stop bit is 1). |
|---|--------------------------------------------------------------------------------|

This bit is cleared to 0 by a write to **UARTECR**.

In FIFO mode, this error is associated with the character at the top of the FIFO.

**Register 3: UART Flag (UARTFR), offset 0x018**

The **UARTFR** register is the flag register. After reset, the TXFF, RXFF, and BUSY bits are 0, and TXFE and RXFE bits are 1.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)

**Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020**

The **UARTILPR** register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset.

The internal IrLPBaud16 clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the IrLPBaud16 clock. The low-power divisor value is calculated as follows:

$$ILPDVSR = SysClk / F_{IrLPBaud16}$$

where  $F_{IrLPBaud16}$  is nominally 1.8432 MHz.

Because the IrLPBaud16 clock is used to sample transmitted data irrespective of mode, the ILPDVSR field must be programmed in both low power and normal mode, such that  $1.42 \text{ MHz} < F_{IrLPBaud16} < 2.12 \text{ MHz}$ , resulting in a low-power pulse duration of 1.41–2.11  $\mu\text{s}$  (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4  $\mu\text{s}$  are accepted as valid pulses.

**Note:** Zero is an illegal value. Programming a zero value results in no IrLPBaud16 pulses being generated.

**Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024**

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD**=0), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 1151 for configuration details.

**Register 7: UART Line Control (UARTLCRH), offset 0x02C**

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

**Register 8: UART Control (UARTCTL), offset 0x030**

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set.

To enable the UART module, the UARTEN bit must be set. If software requires a configuration change in the module, the UARTEN bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

**Note:** The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by clearing bit 4 (FEN) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

**Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034**

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the TXRIS and RXRIS bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**UART Interrupt FIFO Level Select (UARTIFLS)**

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000

## Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

### UART Interrupt Mask (UARTIM)

**Register 11: UART Raw Interrupt Status (UARTRIS), offset 0x03C**

The **UARTRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt. A write has no effect.

**UART Raw Interrupt Status (UARTRIS)**

**Register 12: UART Masked Interrupt Status (UARTMIS), offset 0x040**

The **UARTMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

**UART Masked Interrupt Status (UARTMIS)**

**Register 13: UART Interrupt Clear (UARTICR), offset 0x044**

The **UARTICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt (both raw interrupt and masked interrupt, if enabled) is cleared. A write of 0 has no effect.

Note that bits [3:0] are only implemented on UART1. These bits are reserved on UART0 and UART2.

**UART Interrupt Clear (UARTICR)**

**Register 15: UART 9-Bit Self Address (UART9BITADDR), offset 0x0A4**

The **UART9BITADDR** register is used to write the specific address that should be matched with the receiving byte when the 9-bit Address Mask (**UART9BITAMASK**) is set to 0xFF. This register is used in conjunction with **UART9BITAMASK** to form a match for address-byte received.

**UART 9-Bit Self Address (UART9BITADDR)**

**Register 18: UART Clock Configuration (UARTCC), offset 0xFC8**

The **UARTCC** register controls the baud clock source for the UART module. For more information, see the section called “Peripheral Clock Sources” on page 229.

**Note:** If the PIOSC is used for the UART baud clock, the system clock frequency must be at least 9 MHz in Run mode.

## 17 Quad Synchronous Serial Interface (QSSI)

The TM4C1290NCZAD microcontroller includes four Quad-Synchronous Serial Interface (QSSI) modules. All four of the modules support Advanced and Bi-SSI interfaces as well as a Quad-SSI enhancement to provide faster throughput of data. The QSSI module acts as a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, or Texas Instruments synchronous serial interfaces. The QSSI performs serial-to-parallel conversion on data received from a peripheral device. The transmit and receive paths are buffered with internal, independent FIFO memories allowing up to eight 16-bit values in Legacy mode and 8-bit values in Advanced, Bi-, and Quad-modes. The CPU can access data in these FIFOs as well as the QSSI's control and status information. A  $\mu$ DMA interface is also provided to allow the transmit and receive FIFOs to be programmed as source/destination addresses in the  $\mu$ DMA module.

The TM4C1290NCZAD QSSI modules have the following features:

- Four QSSI channels with Advanced, Bi- and Quad-SSI functionality
- Programmable interface operation for Freescale SPI or Texas Instruments synchronous serial interfaces in Legacy Mode. Support for Freescale interface in Bi- and Quad-SSI mode.
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when four or more entries are available to be written in the FIFO
  - Maskable  $\mu$ DMA interrupts for receive and transmit complete
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock.

### 17.1 Block Diagram

The following figure below shows a block diagram of an QSSI module with Advanced, Bi- and Quad-SSI.

Figure 17-1. QSSI Module with Advanced, Bi-SSI and Quad-SSI Support

17.2 Signal Description

The following table lists the external signals of the QSSI module and describes the function of each. The QSSI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The "Pin Mux/Pin Assignment" column in the following table lists the possible GPIO pin placements for the QSSI signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 754) should be set to choose the QSSI function. The number in

parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 771) to assign the QSSI signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 723. Note that for the QSSI module, when operating in Legacy Mode, SSInXDAT0 functions as SSInTX and SSInXDAT1 functions as SSInRX.

**Table 17-1. SSI Signals (212BGA)**

| Pin Name  | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                                                         |

## 17.3 Functional Description

The QSSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The QSSI also supports the  $\mu$ DMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the  $\mu$ DMA module.  $\mu$ DMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 1247).

### 17.3.1 Bit Rate Generation

The QSSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (SysClk). The clock is first divided by an even prescale value CPSDVSR from 2 to 254, which is programmed in the **SSI Clock Prescale (SSICPSR)** register (see page 1239). The clock is further divided by a value from 1 to 256, which is  $1 + \text{SCR}$ , where SCR is the value programmed in the **SSI Control 0 (SSICR0)** register (see page 1232).

The frequency of the output clock SSInClk is defined by:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

**Note:** SYSCLK or ALTCLK is used as the source for the SSInClk depending on how the CS field in the **SSI Clock Configuration (SSICC)** register is configured. For master legacy mode, the SYSCLK or ALTCLK must be at least two times faster than the SSInClk, with the restriction that SSInClk cannot be faster than 60 MHz. For slave mode, SYSCLK or ALTCLK must be at least 12 times faster than the SSInClk. In slave legacy mode, the maximum frequency of SSInClk is 10 MHz.

See “Synchronous Serial Interface (SSI)” on page 1630 to view legacy SSI and QSSI timing parameters.

### 17.3.2 FIFO Operation

#### 17.3.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 1236), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to a legacy SSI serial conversion and transmission to the attached slave or master, respectively, through the SSInDAT0/SSInTX pin.

In slave mode, the legacy SSI transmits data each time the master initiates a transaction. If the transmit FIFO is empty and the master initiates, the slave transmits the 8th most recent value in the transmit FIFO. If less than 8 values have been written to the transmit FIFO since the SSI module clock was enabled using the Rn bit in the **RCGCSSI** register or if the QSSI is reset using the **SRSSI** register, then 0 is transmitted. Care should be taken to ensure that valid data is in the FIFO as needed. The QSSI can be configured to generate an interrupt or a  $\mu$ DMA request when the FIFO is empty.

**Note:** When operating in Legacy Mode, the QuadSSI's SSInXDAT0 signal functions as SSInTX.

### 17.3.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data using the legacy serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register. If the receive FIFO is full when the master or slave receives new data, the data is held off until the receive FIFO has space.

The SSI only provides an SSIClk while transmitting data. When receiving data in master mode, a dummy write to the **SSIDR** register must be performed before any read so that the SSIClk can be properly received by the slave and allow data to be sent to the receive FIFO of the master.

When configured as a master or slave, serial data received through the SSInDAT1/SSInRX pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

**Note:** When operating in Legacy Mode, the QSSI's SSInXDAT1 signal functions as SSInRX.

### 17.3.3 Advanced, Bi- and Quad- SSI Function

Bi-SSI uses two data pins, SSInXDAT0 and SSInXDAT1, that can be configured to receive or transmit data. In Quad-SSI mode, SSInXDAT0, SSInXDAT1, SSInXDAT2 and SSInXDAT3 allow four bits of data to be received or transmitted at once. Note that in bi- and quad-SSI data transfers are only half-duplex.

By programming the MODE bits in the **SSICR1** register, Advanced, Bi- or Quad- SSI can be enabled. A direction bit, DIR, is provided to program the direction of operation during a Bi- or Quad SSI-transaction. Since Bi- and Quad-SSI cannot be full duplex, the DIR bit defines whether or not the RX FIFO is disabled. In Advanced operation, if the QSSI module TX (write) mode is enabled, the RX FIFO is automatically prevented from receiving any data. When Advanced SSI is in RX (read) mode, it operates as a full-duplex interface.

In Bi- and Quad-SSI mode, because only 8-bit data is allowed, the DSS bit field must be programmed to 0x7 in the **SSICR0** register before transferring data to the Rx and TX FIFOs. For a data transmit, the 8-bit data packet is placed in a TX FIFO entry bits [7:0] and the mode of operation is inserted in the three most significant bits of the TX FIFO entry. The mode of operation bits [15:13] in the TX FIFO are used by the QSSI module for configuring the data on the proper pins. The following modes that may be placed on bits [15:13] of the FIFO entry are:

- Bi-SSI mode (0x1)
- Quad-SSI mode (0x2)
- Advanced SSI mode (0x3)

When data is first written to the TX FIFO, a SSInFss is asserted low indicating the start of a frame. At the end of transmission, bit 12 of the last data entry in the TX FIFO signifies whether a frame is ending. When the EOM bit is 1 it indicates a End of Message (EOM or STOP frame) and SSInFss is subsequently forced high. The EOM bit is cleared in the **SSICR1** register on the same clock that the write to TXFIFO is completed. An EOM bit value of 0 indicates no change in transmission. If TX FIFO is emptied and SSInFss is still asserted low, it remains low but SSInCLK is not pulsed. Likewise, if SSInFss is high when the TX FIFO is empty, it remains high.

During a Bi-SSI transmit frame, data is shifted out by two bits and placed on the corresponding two SSInDATn pins. For a Quad-SSI transmit frame data is shifted out by four bits and placed on the corresponding four SSInDATn pins.

In Bi-, Quad- and Advanced SSI, the lower byte of the Rx FIFO contains received data. The upper byte contains no valid information.

**Note:** While the master is in Bi- or Quad-SSI mode, if the DSS bit in the **SSICR0** register is not set to 0x7, the QSSI module reverts to Legacy mode and behavior is not guaranteed.

The **SSICR1** register bits DIR and MODE are used to program what operation is needed for the next data bytes that are being loaded into the FIFO. Table 17-2 on page 1218 shows available modes of operation:

**Table 17-2. QSSI Transaction Encodings**

| DIR | MODE | Operation                                                                             |
|-----|------|---------------------------------------------------------------------------------------|
| X   | 0x0  | SSI Legacy operation supporting 4 to 16 data bits                                     |
| 0   | 0x1  | Transmit (TX) Bi-SSI with 8-bits of packet data                                       |
| 0   | 0x2  | Transmit (TX) Quad-SSI with 8-bits of packet data                                     |
| 0   | 0x3  | Transmit (TX) Advanced SSI mode with 8-bits of packet data and write RX FIFO disabled |
| 1   | 0x1  | Receive (RX) Bi-SSI with 8-bits of packet data                                        |
| 1   | 0x2  | Receive (RX) Quad-SSI with 8-bits of packet data                                      |
| 1   | 0x3  | Full duplex Advance SSI with 8-bits of packet data                                    |

**Note:** SP0 = 0 and SPH = 0 is the only frame structure allowed for Advanced, Bi- and Quad-mode.

Different transactions can follow one another in the FIFOs. The following transaction combinations are allowed:

- Legacy SSI mode (if configured for this mode, switching to any other alternate mode is not recommended)
- Advanced SSI mode followed by Bi-SSI mode
- Advanced SSI mode followed by Quad-SSI mode
- Advanced SSI mode followed by Bi-SSI mode followed by Advanced SSI mode
- Advanced SSI mode followed by Quad-SSI mode followed by Advanced SSI mode

Note that switching between Quad-SSI and Bi-SSI is not encouraged in a single transaction.

### 17.3.4 SSInFSS Function

For enhanced modes of operation, the SSInFss signal can be programmed to assert low at the start of each byte transfer for one clock or the entire frame. This is configured by programming the FSSHLDFRM bit in the **SSICR1** register. The EOM bit is also provided to signify end of frame transmission. This bit is embedded in the TXFIFO entry for use at the interface to deassert SSInFss at the appropriate time. The FSSHLDFRM bit can also be used when operating in 8-bit Legacy SSI mode.

The functionality of the FSSHLDFRM bit for both Legacy SSI mode and the enhanced modes are as follows:

**Table 17-3. SSInFss Functionality**

| Mode                       | FSSHLDFRM | Description                                                                                                                                                                                                                                                                      |
|----------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Legacy Mode                | 0         | For Freescale format, with SPH = 0, the SSInFss signal is asserted low between continuous transfers. For SPH = 1, the SSInFss signal is deasserted (high) between continuous transfers.<br><br>For TI format, the SSInFss signal is deasserted (high) after every data transfer. |
|                            | 1         | For Freescale format with any SPH value, the SSInFss signal is forced high between continuous transfers; it is asserted low when there is available data in the Tx FIFO; otherwise it is forced high to be ready for a new frame                                                 |
| Advanced/Bi-/Quad-SSI Mode | 0         | SSInFss is asserted low after every byte of data                                                                                                                                                                                                                                 |
|                            | 1         | New data written to the TX FIFO notifies SSInFss to assert low until the Tx FIFO is empty.                                                                                                                                                                                       |

### 17.3.5 High Speed Clock Operation

In master mode, QSSI module can enable a high speed clock by setting the HSCLKEN bit in the **SSI Control 1 (SSICR1)** register. In this mode of operation, SSInCLK from the QSSI master operation is reflected back as a loopback clock, HSPEEDCLK, to the QSSI module. This allows faster timing since the logic can be used to adjust clock to external data relationships. HSPEEDCLK captures RX data in a separate register. This allows the time between the clock as seen by a remote device and the internal clock to match more closely.

Receive data is captured in a separate register sampled on loop-back clock (HSPEEDCLK) and the RX FIFO write control registered on HSPEEDCLK. If the HSCKEN = 1, the corresponding shift register and FIFO write enable will be selected for use. This supports faster QSSI master speed.

**Note:** For proper functionality of high speed mode, the HSCLKEN bit in the **SSICR1** register should be set before any SSI data transfer or after applying a reset to the QSSI module. In addition, the SSE bit must be set to 0x1 before the HSCLKEN bit is set.

### 17.3.6 Interrupts

The QSSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service (when the transmit FIFO is half full or less)
- Receive FIFO service (when the receive FIFO is half full or more)
- Receive FIFO time-out
- Receive FIFO overrun
- End of transmission
- Receive DMA transfer complete
- Transmit DMA transfer complete

All of the interrupt events are ORed together before being sent to the interrupt controller, so the QSSI generates a single interrupt request to the controller regardless of the number of active interrupts. Each of the seven individual maskable interrupts can be masked by clearing the appropriate bit in the **SSI Interrupt Mask (SSIIM)** register (see page 1240). Setting the appropriate mask bit enables the interrupt.

The individual outputs, along with a combined interrupt output, allow use of either a global interrupt service routine or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 1242 and page 1244, respectively).

The RX FIFO has an associated time-out counter which starts to down count at the same time the RX FIFO is flagged as not empty by the RNE bit in the **SSISR** register. The counter is reset any time a new or next byte is written to the RX FIFO, thus the counter will continue to count down to zero unless there is new activity. The time-out period is 32 periods based on the period of SSInClk. When the counter reaches zero, a time-out interrupt bit, RTRIS, is set in the **SSIRIS** register. The time-out interrupt can be cleared by writing a 1 to the RTIC bit of the **SSI Interrupt Clear (SSIC)** register or by emptying the RX FIFO. If the interrupt is cleared and there is residual data left in the RX FIFO or new data entries have been written, the timer count down initiates and the interrupt will be reasserted after 32 periods have been counted.

The End-of-Transmission (EOT) interrupt indicates that the data has been transmitted completely and is only valid for Master mode devices/operations. This interrupt can be used to indicate when it is safe to turn off the QSSI module clock or enter sleep mode. In addition, because transmitted data and received data complete at exactly the same time, the interrupt can also indicate that read data is ready immediately, without waiting for the receive FIFO time-out period to complete.

**Note:** In Freescale SPI mode only, a condition can be created where an EOT interrupt is generated for every byte transferred even if the FIFO is full. If the the  $\mu$ DMA has been configured to transfer data from this QSSI to a Master QSSI on the device using external loopback, an EOT interrupt is generated by the QSSI slave for every byte even if the FIFO is full.

### 17.3.7 Frame Formats

Each data frame is between 4 and 16 bits long in Legacy mode and 8-bits in Advanced/Bi-/Quad-SSI mode and is transmitted starting with the MSB. There are two basic frame types that can be selected by programming the FRF bit in the **SSICR0** register:

- Texas Instruments synchronous serial
- Freescale SPI

**Note:** Advanced, Bi- and Quad-SSI modules only supports Freescale mode when SPH=0; SP0=0 and DDS=0x8 in the **SSI Control 0 (SSICR0)** register.

For both formats, the serial clock (SSInClk) is held inactive while the QSSI is idle, and SSInClk transitions at the programmed frequency only during active transmission or reception of data. The idle state of SSInClk is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI frame format, the serial frame (SSInFss) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the SSInFss pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the QSSI and the off-chip slave device drive their output data on the rising edge of SSInClk and latch data from the other device on the falling edge.

The following table gives a synopsis of the features supported in each frame format when operating in Legacy Mode:

**Table 17-4. Legacy Mode TI, Freescale SPI Frame Format Features**

| Feature                            | TI Mode                  | Freescale SPI Mode                                                           |
|------------------------------------|--------------------------|------------------------------------------------------------------------------|
| Frame Hold                         | Not Available            | Available                                                                    |
| High Speed (Master RX Only)        | Not Available            | Available                                                                    |
| SPO/SPH Configuration              | Not Available            | Available and can be used in combination with Frame Hold and High Speed Mode |
| Frequency (system clock : SSInCLK) | Master 1:2<br>Slave 1:12 | Master 1:2<br>Slave 1:12                                                     |

For Advanced, Bi- and Quad-SSI modes using the Freescale SPI Format or the Bi- and Quad-SSI modes using the TI format, the following features are supported:

- Frame Hold
- High Speed (Master RX Only)
- SPO/SPH Configuration with SP0=0 and SPH=0 only allowed
- Frequency (system clock : SSInCLK):
  - Master 1:2
  - Slave 1:12

#### 17.3.7.1 Texas Instruments Synchronous Serial Frame Format

Figure 17-2 on page 1221 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

**Figure 17-2. TI Synchronous Serial Frame Format (Single Transfer)**

In this mode, SSInClk and SSInFss are forced Low, and the transmit data line SSInDAT0/SSInTX is tristated whenever the QSSI is idle. Once the bottom entry of the transmit FIFO contains data, SSInFss is pulsed High for one SSInClk period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of SSInClk, the MSB of the 4 to 16-bit data frame is shifted out on the SSInDAT0/SSInTX pin. Likewise, the MSB of the received data is shifted onto the SSInDAT1/SSInRX pin by the off-chip serial slave device.

Both the QSSI and the off-chip serial slave device then clock each data bit into their serial shifter on each falling edge of SSInClk. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of SSInClk after the LSB has been latched.

Figure 17-3 on page 1222 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

**Figure 17-3. TI Synchronous Serial Frame Format (Continuous Transfer)**

### 17.3.7.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the SSInFss signal behaves as a slave select. If operating in Legacy Mode and using the Freescale SPI Frame Format, the inactive state and phase of the SSInClk signal are programmable through the SP0 and SPH bits in the **SSICR0** control register. If operating in Advanced/Bi-/Quad-SSI mode, the SP0 and SPH bits must be programmed to 0.

#### **SP0 Clock Polarity Bit**

When the SP0 clock polarity control bit is clear, it produces a steady state Low value on the SSInClk pin. If the SP0 bit is set, a steady state High value is placed on the SSInClk pin when data is not being transferred.

#### **SPH Phase Control Bit**

The SPH phase control bit selects the clock edge that captures data and allows it to change state. The state of this bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the SPH phase control bit is clear, data is captured on the first clock edge transition. If the SPH bit is set, data is captured on the second clock edge transition.

### 17.3.7.3 Freescale SPI Frame Format with SP0=0 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SP0=0 and SPH=0 are shown in Figure 17-4 on page 1223 and Figure 17-5 on page 1223.

**Note:** This is the only Freescale SPI frame format configuration that can be used when operating in Advanced/Bi-/Quad-SSI mode.

**Figure 17-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0**

**Note:** Q is undefined.

**Figure 17-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0**

In this configuration, during idle periods:

- SSInClk is forced Low
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is tristated
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low, causing slave data to be enabled onto the SSInDAT1/SSInRX input line of the master. The master SSInDAT0/SSInTX output pad is enabled.

One half SSInClk period later, valid master data is transferred to the SSInDAT0/SSInTX pin. Once both the master and slave data have been set, the SSInClk master clock pin goes High after one additional half SSInClk period.

The data is now captured on the rising and propagated on the falling edges of the SSInClk signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the SSInFss line is returned to its idle High state one SSInClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSInFss signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the SSInFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSInFss pin is returned to its idle state one SSInClk period after the last bit has been captured.

#### 17.3.7.4 Freescale SPI Frame Format with SPO=0 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=0 and SPH=1 is shown in Figure 17-6 on page 1224, which covers both single and continuous transfers.

**Note:** This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

**Figure 17-6. Freescale SPI Frame Format with SPO=0 and SPH=1**

**Note:** Q is undefined.

In this configuration, during idle periods:

- SSInClk is forced Low
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is tristated
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low. The master SSInDAT0/SSInTX output is enabled. After an additional one-half SSInClk period, both master and slave valid data are enabled onto their respective transmission lines. At the same time, the SSInClk is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the SSInClk signal.

In the case of a single word transfer, after all bits have been transferred, the SSInFss line is returned to its idle High state one SSInClk period after the last bit has been captured.

For continuous back-to-back transfers, the SSInFss pin is held Low between successive data words, and termination is the same as that of the single word transfer.

#### 17.3.7.5 Freescale SPI Frame Format with SPO=1 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=1 and SPH=0 are shown in Figure 17-7 on page 1225 and Figure 17-8 on page 1225.

**Note:** This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

**Figure 17-7. Freescale SPI Frame Format (Single Transfer) with SPO=1 and SPH=0**

**Note:** Q is undefined.

**Figure 17-8. Freescale SPI Frame Format (Continuous Transfer) with SPO=1 and SPH=0**

In this configuration, during idle periods:

- SSInClk is forced High
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is tristated
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low, causing slave data to be immediately transferred onto the SSInDAT1/SSInRX line of the master. The master SSInDAT0/SSInTX output pad is enabled.

One-half period later, valid master data is transferred to the SSInDAT0/SSInTX line. Once both the master and slave data have been set, the SSInClk master clock pin becomes Low after one additional half SSInClk period, meaning that data is captured on the falling edges and propagated on the rising edges of the SSInClk signal.

In the case of a single word transmission, after all bits of the data word are transferred, the SSInFss line is returned to its idle High state one SSInClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSInFss signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the SSInFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSInFss pin is returned to its idle state one SSInClk period after the last bit has been captured.

### 17.3.7.6 Freescale SPI Frame Format with SPO=1 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=1 and SPH=1 is shown in Figure 17-9 on page 1226, which covers both single and continuous transfers.

**Note:** This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

**Figure 17-9. Freescale SPI Frame Format with SPO=1 and SPH=1**

**Note:** Q is undefined.

In this configuration, during idle periods:

- SSInClk is forced High
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is tristated
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low. The master SSInDAT0/SSInTX output pad is enabled. After an additional one-half SSInClk period, both master and slave data are enabled onto their respective transmission lines. At the same time, SSInClk is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SSInClk signal.

After all bits have been transferred, in the case of a single word transmission, the SSInFss line is returned to its idle high state one SSInClk period after the last bit has been captured.

For continuous back-to-back transmissions, the SSInFss pin remains in its active Low state until the final bit of the last word has been captured and then returns to its idle state as described above.

For continuous back-to-back transfers, the SSInFss pin is held Low between successive data words and termination is the same as that of the single word transfer.

### 17.3.8 DMA Operation

The QSSI peripheral provides an interface to the  $\mu$ DMA controller with separate channels for transmit and receive. The  $\mu$ DMA operation of the QSSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When  $\mu$ DMA operation is enabled, the QSSI asserts a  $\mu$ DMA request on the receive or transmit channel when the associated FIFO can transfer data.

For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever at least one empty location is in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst  $\mu$ DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending how the  $\mu$ DMA channel is configured.

To enable  $\mu$ DMA operation for the receive channel, the RXDMAE bit of the **DMA Control (SSIDMACTL)** register should be set after configuring the  $\mu$ DMA. To enable  $\mu$ DMA operation for the transmit channel, the TXDMAE bit of **SSIDMACTL** should be set after configuring the  $\mu$ DMA.

If the  $\mu$ DMA is enabled and has completed a data transfer from the Tx FIFO, the DMATXRIS bit is set in the **SSIRIS** register and cannot be cleared by setting the DMATXIC bit in the **SSI Interrupt Clear (SSIICR)** register. In the DMA Completion Interrupt Service Routine, software must disable the  $\mu$ DMA transmit enable to the SSI by clearing the TXDMAE bit in the **QSSI DMA Control (SSIDMACTL)** register and then setting the DMATXIC bit in the **SSIICR** register. This clears the DMA completion interrupt. When the  $\mu$ DMA is needed to transmit more data, the TXDMAE bit must be set (enabled) again.

If a data transfer by the  $\mu$ DMA from the Rx FIFO completes, the DMARXRIS bit is set. The EOT bit in the **SSIRIS** register is also provided to indicate when the Tx FIFO is empty and the last bit has been transmitted out of the serializer.

**Note:** Wait states are inserted at every byte transfer when using Bi- or Quad-SSI modes as a master with the  $\mu$ DMA at SSICLK frequencies greater than 1/6 of the system clock. These wait states are because of arbitration stall cycles from the  $\mu$ DMA accesses to SRAM and increased output throughput from the SSI.

See “Micro Direct Memory Access ( $\mu$ DMA)” on page 659 for more details about programming the  $\mu$ DMA controller.

## 17.4 Initialization and Configuration

To enable and initialize the QSSI, the following steps are necessary:

1. Enable the QSSI module using the **RCGCSSI** register (see page 381).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 373). To find out which GPIO port to enable, refer to Table 25-5 on page 1569.
3. Set the GPIO AFSEL bits for the appropriate pins (see page 754). To determine which GPIOs to configure, see Table 25-4 on page 1556.
4. Configure the PMcN fields in the **GPIOPCTL** register to assign the QSSI signals to the appropriate pins. See page 771 and Table 25-5 on page 1569.
5. Program the **GPIODEN** register to enable the pin's digital function. In addition, the drive strength, drain select and pull-up/pull-down functions must be configured. Refer to "General-Purpose Input/Outputs (GPIOs)" on page 723 for more information.

**Note:** Pull-ups can be used to avoid unnecessary toggles on the QSSI pins, which can take the slave to a wrong state. In addition, if the SSIClk signal is programmed to steady state High through the SP0 bit in the **SSICR0** register, then software must also configure the GPIO port pin corresponding to the SSInCk signal as a pull-up in the **GPIO Pull-Up Select (GPIOPUR)** register.

For each of the frame formats, the QSSI is configured using the following steps:

1. If initializing out of reset, ensure that the SSE bit in the **SSICR1** register is clear before making any configuration changes. Otherwise, configuration changes for Advanced SSI can be made while the SSE bit is set.
2. Select whether the QSSI is a master or slave:
  - a. For master operations, set the **SSICR1** register to 0x0000.0000.
  - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
  - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the QSSI clock source by writing to the **SSICC** register.
4. Configure the clock prescale divisor by writing the **SSICPSR** register.
5. Write the **SSICR0** register with the following configuration:
  - Serial clock rate (SCR)
  - Desired clock phase/polarity, if using Freescale SPI mode (SPH and SP0)
  - The protocol mode: Freescale SPI or TI SSF
  - The data size (DSS)
6. Optionally, configure the SSI module for  $\mu$ DMA use with the following steps:
  - a. Configure a  $\mu$ DMA for SSI use. See "Micro Direct Memory Access ( $\mu$ DMA)" on page 659 for more information.
  - b. Enable the SSI Module's TX FIFO or RX FIFO by setting the TXDMAE or RXDMAE bit in the **SSIDMACTL** register.

- c. Optionally, enable the  $\mu$ DMA completion interrupt by setting the DMATXIM or DMARXIM bit in the **SSIIM** register.

**Note:** For a TX DMA completion interrupt, software must disable the  $\mu$ DMA transmit enable to the SSI by clearing the TXDMAE bit in the **QSSI DMA Control (SSIDMACTL)** register and then setting the DMATXIC bit in the **SSIICR** register. This clears the DMA completion interrupt. When the  $\mu$ DMA is needed to transmit more data, the TXDMAE bit must be set (enabled) again.

7. If this is the first initialization out of reset, enable the QSSI by setting the SSE bit in the **SSICR1** register.

As an example, assume the QSSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (SPO=1, SPH=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

$$1 \times 10^6 = 20 \times 10^6 / (\text{CPSDVSR} * (1 + \text{SCR}))$$

In this case, if CPSDVSR=0x2, SCR must be 0x9.

The configuration sequence would be as follows:

1. Ensure that the SSE bit in the **SSICR1** register is clear.
2. Write the **SSICR1** register with a value of 0x0000.0000.
3. Write the **SSICPSR** register with a value of 0x0000.0002.
4. Write the **SSICR0** register with a value of 0x0000.09C7.
5. The QSSI is then enabled by setting the SSE bit in the **SSICR1** register.

### 17.4.1 Enhanced Mode Configuration

If the QSSI module supports the Advanced/Bi-/Quad features, then these modes can be enabled after initializing the QSSI module. Below is an example of configuring the QSSI to transmit two data bytes in Advanced SSI mode followed by 2 bytes in Bi-SSI mode:

1. Set the MODE bit to 0x3, and the FSSHDFM bit to 1 in the **SSICR1** register. To operate in the master mode, program the MS bit to 0. Program the remaining bits in the **SSICR0** and **SSICR1** register to relevant values.
2. Write one data byte to the TX FIFO; set the EOM bit to 1 and write the second data byte to the Tx FIFO.

3. Set the MODE bit to 0x1 and the FSSHDFM bit to 1 in the **SSICR1** register. To operate in the master mode, program the MS bit to 0. Program the remaining bits in the **SSICR0** and **SSICR1** register to relevant values.
4. Fill the Tx FIFO with one data byte.
5. Set the EOM bit in the **SSICR1** register.
6. Fill the Tx FIFO with one data byte.

## 17.5 Register Map

Table 17-5 on page 1230 lists the QSSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that QSSI module's base address:

- QSSI0: 0x4000.8000
- QSSI1: 0x4000.9000
- QSSI2: 0x4000.A000
- QSSI3: 0x4000.B000

Note that the QSSI module clock must be enabled before the registers can be programmed (see page 381). The Rn bit of the **PRSSI** register must be read as 0x1 before any QSSI module registers are accessed.

**Table 17-5. SSI Register Map**

| Offset | Name         | Type | Reset       | Description                      | See page |
|--------|--------------|------|-------------|----------------------------------|----------|
| 0x000  | SSICR0       | RW   | 0x0000.0000 | QSSI Control 0                   | 1232     |
| 0x004  | SSICR1       | RW   | 0x0000.0000 | QSSI Control 1                   | 1234     |

## 17.6 Register Descriptions

The remainder of this section lists and describes the QSSI registers, in numerical order by address offset.

**Register 1: QSSI Control 0 (SSICR0), offset 0x000**

The **SSICR0** register contains bit fields that control various functions within the QSSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

**QSSI Control 0 (SSICR0)**

QSSI0 base: 0x4000.8000  
 QSSI1 base: 0x4000.9000  
 QSSI2 base: 0x4000.A000  
 QSSI3 base: 0x4000.B000  
 Offset 0x000  
 Type RW, reset 0x0000.0000

| Bit/Field | Name                                                                                       | Type | Reset  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |       |             |   |                                                        |   |                                                                                            |
|-----------|--------------------------------------------------------------------------------------------|------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------------|---|--------------------------------------------------------|---|--------------------------------------------------------------------------------------------|
| 31:16     | reserved                                                                                   | RO   | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                                                                                                                                                                                                                                    |       |             |   |                                                        |   |                                                                                            |
| 15:8      | SCR                                                                                        | RW   | 0x00   | <p>QSSI Serial Clock Rate</p> <p>This bit field is used to generate the transmit and receive bit rate of the QSSI. The bit rate is:</p> $BR = SysClk / (CPSDVSR * (1 + SCR))$ <p>where CPSDVSR is an even value from 2-254 programmed in the <b>SSICPSR</b> register, and SCR is a value from 0-255.</p>                                                                                                                                                                                                                                                                                                         |       |             |   |                                                        |   |                                                                                            |
| 7         | SPH                                                                                        | RW   | 0      | <p>QSSI Serial Clock Phase</p> <p>This bit is only applicable to the Freescale SPI Format.</p> <p>The SPH control bit selects the clock edge that captures data and allows it to change state. This bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge.</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>Data is captured on the first clock edge transition.</td></tr><tr><td>1</td><td>Data is captured on the second clock edge transition.</td></tr></tbody></table> | Value | Description | 0 | Data is captured on the first clock edge transition.   | 1 | Data is captured on the second clock edge transition.                                      |

**Register 2: QSSI Control 1 (SSICR1), offset 0x004**

The **SSICR1** register contains bit fields that control various functions within the QSSI module. Master and slave mode functionality is controlled by this register.

**QSSI Control 1 (SSICR1)**

QSSI0 base: 0x4000.8000  
 QSSI1 base: 0x4000.9000  
 QSSI2 base: 0x4000.A000  
 QSSI3 base: 0x4000.B000  
 Offset 0x004  
 Type RW, reset 0x0000.0000

**Register 3: QSSI Data (SSIDR), offset 0x008**

**Important:** This register is read-sensitive. See the register description for details.

The **SSIDR** register is 16-bits wide. When the **SSIDR** register is read, the entry in the receive FIFO that is pointed to by the current FIFO read pointer is accessed. When a data value is removed by the QSSI receive logic from the incoming data frame, it is placed into the entry in the receive FIFO pointed to by the current FIFO write pointer.

When the **SSIDR** register is written to, the entry in the transmit FIFO that is pointed to by the write pointer is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. Each data value is loaded into the transmit serial shifter, then serially shifted out onto the SSInDAT0/SSInTX pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

**Register 5: QSSI Clock Prescale (SSICPSR), offset 0x010**

The **SSICPSR** register specifies the division factor which is used to derive the SSInClk from the system clock. The clock is further divided by a value from 1 to 256, which is 1 + SCR. SCR is programmed in the **SSICR0** register. The frequency of the SSInClk is defined by:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

**Register 6: QSSI Interrupt Mask (SSIIM), offset 0x014**

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared on reset.

On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit clears the mask, enabling the interrupt to be sent to the interrupt controller. Clearing a bit sets the corresponding mask, preventing the interrupt from being signaled to the controller.

**Register 9: QSSI Interrupt Clear (SSIICR), offset 0x020**

The **SSIICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

**QSSI Interrupt Clear (SSIICR)**

**Register 13: QSSI Peripheral Identification 4 (SSIPeriphID4), offset 0xFD0**

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

## QSSI Peripheral Identification 4 (SSIPeriphID4)

QSSI0 base: 0x4000.8000  
 QSSI1 base: 0x4000.9000  
 QSSI2 base: 0x4000.A000  
 QSSI3 base: 0x4000.B000  
 Offset 0xFD0  
 Type RO, reset 0x0000.0000

## 18 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacturing. The TM4C1290NCZAD microcontroller includes providing the ability to communicate (both transmit and receive) with other I<sup>2</sup>C devices on the bus.

The TM4C1290NCZAD controller includes I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both transmitting and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Two 8-entry FIFOs for receive and transmit data
  - FIFOs can be independently assigned to master or slave
- Four transmission speeds:
  - Standard (100 Kbps)
  - Fast-mode (400 Kbps)
  - Fast-mode plus (1 Mbps)
  - High-speed mode (3.33 Mbps)
- Glitch suppression
- SMBus support through software
  - Clock low timeout interrupt
  - Dual slave address capability
  - Quick command capability
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)

- Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive
  - Ability to execute single data transfers or burst data transfers using the RX and TX FIFOs in the I<sup>2</sup>C

## 18.1 Block Diagram

Figure 18-1. I<sup>2</sup>C Block Diagram

## 18.2 Signal Description

The following table lists the external signals of the I<sup>2</sup>C interface and describes the function of each. The I<sup>2</sup>C interface signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the I<sup>2</sup>C signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 754) should be set to choose the I<sup>2</sup>C function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPTCL)** register (page 771) to assign the I<sup>2</sup>C signal to the specified GPIO port pin. Note that the I2CSDA pin should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 723.

**Table 18-1. I2C Signals (212BGA)**

| Pin Name | Pin Number                    | Pin Mux / Pin Assignment                            | Pin Type | Buffer Type | Description                                                                                                                                      |

## 18.3 Functional Description

Each I<sup>2</sup>C module is comprised of both master and slave functions and is identified by a unique address. A master-initiated communication generates the clock signal, SCL. For proper operation, the SDA pin must be configured as an open-drain signal. Due to the internal circuitry that supports high-speed operation, the SCL pin must not be configured as an open-drain signal, although the internal circuitry causes it to act as if it were an open drain signal. Both SDA and SCL signals must be connected to a positive supply voltage using a pull-up resistor. A typical I<sup>2</sup>C bus configuration is shown in Figure 18-2. Refer to the *I<sup>2</sup>C-bus specification and user manual* to determine the size of the pull-ups needed for proper operation.

See “Inter-Integrated Circuit (I<sup>2</sup>C) Interface” on page 1633 for I<sup>2</sup>C timing diagrams.

Figure 18-2. I<sup>2</sup>C Bus Configuration

### 18.3.1 I<sup>2</sup>C Bus Functional Overview

The I<sup>2</sup>C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on TM4C1290NCZAD microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the I<sup>2</sup>C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 1266) is unrestricted, but each data byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

### 18.3.1.1 START and STOP Conditions

The protocol of the I<sup>2</sup>C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 18-3.

**Figure 18-3. START and STOP Conditions**

The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due to an error), the interrupt pin becomes active and the data may be read from the **I<sup>2</sup>C Master Data (I2CMDR)** register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit is normally set causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

When operating in slave mode, the STARTRIS and STOPRIS bits in the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register indicate detection of start and stop conditions on the bus and the **I<sup>2</sup>C Slave Masked Interrupt Status (I2CSMIS)** register can be configured to allow STARTRIS and STOPRIS to be promoted to controller interrupts (when interrupts are enabled).

### 18.3.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 18-4. After the START condition, a slave address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (R/S bit in the **I2CMSA** register). If the R/S bit is clear, it indicates a transmit operation (send), and if it is set, it indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/transmit formats are then possible within a single transfer.

**Figure 18-4. Complete Data Transfer with a 7-Bit Address**

The first seven bits of the first byte make up the slave address (see Figure 18-5). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

**Figure 18-5. R/S Bit in First Byte**

### 18.3.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 18-6).

**Figure 18-6. Data Validity During Bit Transfer on the I<sup>2</sup>C Bus**

### 18.3.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data transmitted out by the receiver during the acknowledge cycle must comply with the data validity requirements described in “Data Validity” on page 1267.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Because the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

If the slave is required to provide a manual ACK or NACK, the **I<sup>2</sup>C Slave ACK Control (I2CSACKCTL)** register allows the slave to NACK for invalid data or command or ACK for valid data or command. When this operation is enabled, the MCU slave module I<sup>2</sup>C clock is pulled low after the last data bit until this register is written with the indicated response.

### 18.3.1.5 Repeated Start

The I<sup>2</sup>C master module has the capability of executing a repeated START (transmit or receive) after an initial transfer has occurred.

A repeated start sequence for a Master transmit is as follows:

1. When the device is in the idle state, the Master writes the slave address to the **I2CMSA** register and configures the R/S bit for the desired transfer type.
2. Data is written to the **I2CMDR** register.
3. When the BUSY bit in the **I2CMCS** register is 0, the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSA** register and then writes 0x3 to initiate the repeated START.

A repeated start sequence for a Master receive is similar:

1. When the device is in idle, the Master writes the slave address to the **I2CMSA** register and configures the R/S bit for the desired transfer type.
2. The master reads data from the **I2CMDR** register.
3. When the BUSY bit in the **I2CMCS** register is 0, the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSA** register and then writes 0x3 to initiate the repeated START.

For more information on repeated START, refer to Figure 18-12 on page 1281 and Figure 18-13 on page 1282.

### 18.3.1.6 Clock Low Timeout (CLTO)

The I<sup>2</sup>C slave can extend the transaction by pulling the clock low periodically to create a slow bit transfer rate. The I<sup>2</sup>C module has a 12-bit programmable counter that is used to track how long the clock has been held low. The upper 8 bits of the count value are software programmable through the **I<sup>2</sup>C Master Clock Low Timeout Count (I2CMCLKOCNT)** register. The lower four bits are not user visible and are 0x0. The CNTL value programmed in the **I2CMCLKOCNT** register has to be greater than 0x01. The application can program the eight most significant bits of the counter to reflect the acceptable cumulative low period in transaction. The count is loaded at the START condition and counts down on each falling edge of the internal bus clock of the Master. Note that the internal bus clock generated for this counter keeps running at the programmed I<sup>2</sup>C speed even if SCL is held low on the bus. Upon reaching terminal count, the master state machine forces ABORT on the bus by issuing a STOP condition at the instance of SCL and SDA release.

As an example, if an I<sup>2</sup>C module was operating at 100 kHz speed, programming the **I2CMCLKOCNT** register to 0xDA would translate to the value 0xDA0 since the lower four bits are set to 0x0. This would translate to a decimal value of 3488 clocks or a cumulative clock low period of 34.88 ms at 100 kHz.

The CLKRIS bit in the **I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS)** register is set when the clock timeout period is reached, allowing the master to start corrective action to resolve the remote slave state. In addition, the CLKTO bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register is set; this bit

is cleared when a STOP condition is sent or during the I<sup>2</sup>C master reset. The status of the raw SDA and SCL signals are readable by software through the SDA and SCL bits in the **I<sup>2</sup>C Master Bus Monitor (I2CMBMON)** register to help determine the state of the remote slave.

In the event of a CLTO condition, application software must choose how it intends to attempt bus recovery. Most applications may attempt to manually toggle the I<sup>2</sup>C pins to force the slave to let go of the clock signal (a common solution is to attempt to force a STOP on the bus). If a CLTO is detected before the end of a burst transfer, and the bus is successfully recovered by the master, the master hardware attempts to finish the pending burst operation. Depending on the state of the slave after bus recovery, the actual behavior on the bus varies. If the slave resumes in a state where it can acknowledge the master (essentially, where it was before the bus hang), it continues where it left off. However, if the slave resumes in a reset state (or if a forced STOP by the master causes the slave to enter the idle state), it may ignore the master's attempt to complete the burst operation and NAK the first data byte that the master sends or requests.

Since the behavior of slaves cannot always be predicted, it is suggested that the application software always write the STOP bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register during the CLTO interrupt service routine. This limits the amount of data the master attempts to send or receive upon bus recovery to a single byte, and after the single byte is on the wire, the master issues a STOP. An alternative solution is to have the application software reset the I<sup>2</sup>C peripheral before attempting to manually recover the bus. This solution allows the I<sup>2</sup>C master hardware to be returned to a known good (and idle) state before attempting to recover a stuck bus and prevents any unwanted data from appearing on the wire.

**Note:** The Master Clock Low Timeout counter counts for the entire time SCL is held Low continuously. If SCL is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the **I2CMCLKOCNT** register and begins counting down from this value.

#### 18.3.1.7 Dual Address

The I<sup>2</sup>C interface supports dual address capability for the slave. The additional programmable address is provided and can be matched if enabled. In legacy mode with dual address disabled, the I<sup>2</sup>C slave provides an ACK on the bus if the address matches the OAR field in the **I2CSOAR** register. In dual address mode, the I<sup>2</sup>C slave provides an ACK on the bus if either the OAR field in the **I2CSOAR** register or the OAR2 field in the **I2CSOAR2** register is matched. The enable for dual address is programmable through the OAR2EN bit in the **I2CSOAR2** register and there is no disable on the legacy address.

The OAR2SEL bit in the **I2CSCSR** register indicates if the address that was ACKed is the alternate address or not. When this bit is clear, it indicates either legacy operation or no address match.

#### 18.3.1.8 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a 1 (High) on SDA, while another master transmits a 0 (Low), switches off its data output stage and retires until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

If arbitration is lost when the I2C master is initiating a BURST with the TX FIFO enabled, the application should execute the following steps to correctly handle the arbitration loss:

1. Flush and disable the TX FIFO
2. Clear and mask the TXFE interrupt by clearing the TXFEIM bit in the **I2CMIMR** register.

Once the bus is IDLE, the TXFIFO can be filled and enabled, the TXFE bit can be unmasked and a new BURST transaction can be initiated.

### 18.3.1.9 Glitch Suppression in Multi-Master Configuration

When a multi-master configuration is being used, the PULSESEL bit in the **I2CMTPR** register can be programmed to provide glitch suppression on the SCL and SDA lines and assure proper signal values. The glitch suppression value is in terms of buffered system clocks. Note that all signals will be delayed internally when glitch suppression is nonzero. For example, if PULSESEL is set to 0x7, 31 clocks should be added onto the calculation for the expected transaction time.

### 18.3.1.10 SMBus Operation

The SMBus interface is based on the I<sup>2</sup>C protocol; however, some differences exist between the two. These differences must be handled through software in order to make sure the SMBus protocol, including timing specifications, is met. Note that the SMBus 2.0 specification limits the maximum frequency of the interface to 100 KHz, as a result, I<sup>2</sup>C Standard speed operation is used for SMBus.

The SMBus/ I<sup>2</sup>C slave can extend the transaction if it is not ready by pulling the clock low. The SMBus specification allows the maximum timeout for such elongated transaction to be between 25 to 35 ms. The I<sup>2</sup>C specification does not have this requirement. The I<sup>2</sup>C module supports a programmable count to support clock-low timeout for the master to error out and take appropriate action as required. This feature is explained in "Clock Low Timeout (CLTO)" on page 1268. Note that if transactions are extended, a timeout period should be programmed in the **I2CMCLKOCNT** register, and the CLKRIS bit in the **I2CMRIS** register should not be masked.

Unlike the I<sup>2</sup>C slave, the SMBus slave must respond with an ACK response to its address regardless of whether it is ready or not. As a result, the I<sup>2</sup>C slave sends an ACK response to its address and a NACK response on the data byte if it is not ready. The ARBLST bit in the **I2CMCS** register is set if there were any issues with the transfer. In addition, the slave can send a NACK at any time to force the master to stop sending additional bytes.

The I<sup>2</sup>C Interface supports  $\mu$ DMA for efficient data handling. The  $\mu$ DMA operation needs FIFOs to be enabled for appropriate transfer type to perform I<sup>2</sup>C Master for burst transfers and all types of Slave transfers. The I<sup>2</sup>C interface is supported by two channels, one for Rx (I<sup>2</sup>C to Memory) and one for Tx (Memory to I<sup>2</sup>C) transfers.. See "FIFO and  $\mu$ DMA Operation" on page 1274 for more information.

#### Quick Command

Quick Command is a simple, compact SMBus protocol that sends an address and 1-bit of data in the R/S bit of the I<sup>2</sup>C header byte to communicate a command to the slave, typically a "turn off" or "turn on". The I<sup>2</sup>C master peripheral has the ability to send a Quick Command by writing the target address and R/S value into the **I2CMSA** register followed by a write to **I2CMCS** with a value of 0x27. SMBus requires the slave to be able to accept and process commands and the master to generate the Quick Command transactions. The master also has the capability to stop the transaction after acknowledgement from a slave.

The I<sup>2</sup>C slave peripheral requires special handling when a Quick Command is sent. In the case where a master sends a Quick Command with the R/S (data) bit cleared, the QCMDST bit in **I2CSCSR** is set, and the QCMDRW bit shows the data value (which in this case is 0) when the STOPRIS bit is set in **I2CSRIS** and the STOP interrupt is asserted. In this scenario, a DATARIS interrupt bit is not

set. When the master sends a Quick Command with the R/S (data) bit set, the DATARIS bit is set to notify the slave to write a data byte to **I2CSDR** in which bit 7 is set. A “dummy write” of 0xFF to the **I2CSDR** register is recommended. After the write to **I2CSDR**, the STOP interrupt is asserted and the QCMDST and QCMDRW bits are set in the **I2CSCSR** register to indicate that a quick command read occurred and the last transaction was a Quick Command. Therefore, when the slave must receive a Quick Command, it should be expecting such a command because it must write the **I2CSDR** with a specific value when R/S is set.

### 18.3.2 Available Speed Modes

The I<sup>2</sup>C bus can run in Standard mode (100 kbps), Fast mode (400 kbps), Fast mode plus (1 Mbps) or High-Speed mode (3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines). The selected mode should match the speed of the other I<sup>2</sup>C devices on the bus.

#### 18.3.2.1 Standard, Fast, and Fast Plus Modes

Standard, Fast, and Fast Plus modes are selected using a value in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register that results in an SCL frequency of 100 kbps for Standard mode, 400 kbps for Fast mode, or 1 Mbps for Fast mode plus.

The I<sup>2</sup>C clock rate is determined by the parameters *CLK\_PRD*, *TIMER\_PRD*, *SCL\_LP*, and *SCL\_HP* where:

*CLK\_PRD* is the system clock period

*SCL\_LP* is the low phase of SCL (fixed at 6)

*SCL\_HP* is the high phase of SCL (fixed at 4)

*TIMER\_PRD* is the programmed value in the **I2CMTPR** register (see page 1300). This value is determined by replacing the known variables in the equation below and solving for *TIMER\_PRD*.

The I<sup>2</sup>C clock period is calculated as follows:

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD$$

For example:

$$CLK\_PRD = 50 \text{ ns}$$

$$TIMER\_PRD = 2$$

$$SCL\_LP = 6$$

$$SCL\_HP = 4$$

yields a SCL frequency of:

$$1/SCL\_PERIOD = 333 \text{ KHz}$$

Table 18-2 gives examples of the timer periods that should be used to generate Standard, Fast mode, and Fast mode plus SCL frequencies based on various system clock frequencies.

**Table 18-2. Examples of I<sup>2</sup>C Master Timer Period Versus Speed Mode**

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode | Timer Period | Fast Mode Plus |
|--------------|--------------|---------------|--------------|-----------|--------------|----------------|
| 4 MHz        | 0x01         | 100 Kbps      | -            | -         | -            | -              |
| 6 MHz        | 0x02         | 100 Kbps      | -            | -         | -            | -              |

**Table 18-2. Examples of I<sup>2</sup>C Master Timer Period Versus Speed Mode (continued)**

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode | Timer Period | Fast Mode Plus |
|--------------|--------------|---------------|--------------|-----------|--------------|----------------|
| 12.5 MHz     | 0x06         | 89 Kbps       | 0x01         | 312 Kbps  | -            | -              |
| 16.7 MHz     | 0x08         | 93 Kbps       | 0x02         | 278 Kbps  | -            | -              |
| 20 MHz       | 0x09         | 100 Kbps      | 0x02         | 333 Kbps  | -            | -              |

| 120 MHz      | 0x3B         | 100 Kbps      | 0xE          | 400 Kbps  | 0x5          | 1000 Kbps      |

**18.3.2.2 High-Speed Mode**

The TM4C1290NCZAD I<sup>2</sup>C peripheral has support for High-speed operation as both a master and slave. High-Speed mode is configured by setting the HS bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register. High-Speed mode transmits data at a high bit rate with a 66.6%/33.3% duty cycle, but communication and arbitration are done at Standard, Fast mode, or Fast-mode plus speed, depending on which is selected by the user. When the HS bit in the **I2CMCS** register is set, current mode pull-ups are enabled.

The clock period can be selected using the equation below, but in this case, SCL\_LP=2 and SCL\_HP=1.

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD$$

So for example:

CLK\_PRD = 25 ns

TIMER\_PRD = 1

SCL\_LP=2

SCL\_HP=1

yields a SCL frequency of:

$$1/T = 3.33 \text{ Mhz}$$

Table 18-3 on page 1272 gives examples of timer period and system clock in High-Speed mode. Note that the HS bit in the **I2CMTPR** register needs to be set for the TPR value to be used in High-Speed mode.

**Table 18-3. Examples of I<sup>2</sup>C Master Timer Period in High-Speed Mode**

| System Clock | Timer Period | Transmission Mode |
|--------------|--------------|-------------------|
| 40 MHz       | 0x01         | 3.33 Mbps         |
| 50 MHz       | 0x02         | 2.77 Mbps         |
| 80 MHz       | 0x03         | 3.33 Mbps         |

When operating as a master, the protocol is shown in Figure 18-7. The master is responsible for sending a master code byte in either Standard (100 Kbps) or Fast-mode (400 Kbps) before it begins

transferring in High-speed mode. The master code byte must contain data in the form of 0000.1XXX and is used to tell the slave devices to prepare for a High-speed transfer. The master code byte should never be acknowledged by a slave since it is only used to indicate that the upcoming data is going to be transferred at a higher data rate. To send the master code byte for a standard high-speed transfer, software should place the value of the master code byte into the **I2CMSA** register and write the **I2CMCS** register with a value of 0x13. If a high-speed burst transfer is required, then to send the master code byte, software should place the value of the master code byte into the **I2CMSA** register and write the **I2CMCS** register with 0x50. Either configuration places the I<sup>2</sup>C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the HS bit in the **I2CMCS** register. Again, setting the HS bit in the **I2CMCS** register is only necessary during the master code byte.

When operating as a High-speed slave, there is no additional software required.

**Figure 18-7. High-Speed Data Format**

**Note:** High-Speed mode is 3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines.

### 18.3.3 Interrupts

The I<sup>2</sup>C can generate interrupts when the following conditions are observed in the Master Module:

- Master transaction completed (RIS bit)
- Master arbitration lost (ARBL0STRIS bit)
- Master Address/Data NACK (NACKRIS bit)
- Master bus timeout (CLKRIS bit)
- Next byte request (RIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)

- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

Interrupts are generated when the following conditions are observed in the Slave Module:

- Slave transaction received (DATARIS bit)
- Slave transaction requested (DATARIS bit)
- Slave next byte transfer request (DATARIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Programmable trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Programmable trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)
- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

The I<sup>2</sup>C master and I<sup>2</sup>C slave modules have separate interrupt registers. Interrupts can be masked by clearing the appropriate bit in the **I<sup>2</sup>C MIMR** or **I<sup>2</sup>C SIMR** register. Note that the RIS bit in the **Master Raw Interrupt Status (I<sup>2</sup>CMRIS)** register and the DATARIS bit in the **Slave Raw Interrupt Status (I<sup>2</sup>CSRIS)** register have multiple interrupt causes including a next byte transfer request interrupt. This interrupt is generated when both master and slave are requesting a receive or transmit transaction.

#### **18.3.4 Loopback Operation**

The I<sup>2</sup>C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the LPBK bit in the **I<sup>2</sup>C Master Configuration (I<sup>2</sup>CMCR)** register. In loopback mode, the SDA and SCL signals from the master and are tied to the SDA and SCL signals of the slave module to allow internal testing of the device without having to go through I/O.

#### **18.3.5 FIFO and $\mu$ DMA Operation**

Both the master and the slave module have the capability to access two 8-byte FIFOs that can be used in conjunction with the  $\mu$ DMA for fast transfer of data. The transmit (TX) FIFO and receive (RX) FIFO can be independently assigned to either the I<sup>2</sup>C master or I<sup>2</sup>C slave. Thus, the following FIFO assignments are allowed:

- The transmit and receive FIFOs can be assigned to the master
- The transmit and receive FIFOs can be assigned to the slave

- The transmit FIFO can be assigned to the master, while the receive FIFO is assigned to the slave and vice versa.

In most cases, both FIFOs will be assigned to either the master or the slave. The FIFO assignment is configured by programming the TXASGNMT and RXASGNMT bit in the **I<sup>2</sup>C FIFO Control (I2CFIFOCTL)** register.

Each FIFO has a programmable threshold point which indicates when the FIFO service interrupt should be generated. Additionally, a FIFO receive full and transmit empty interrupt can be enabled in the Interrupt Mask (**I2CxIMR**) registers of both the master and slave. Note that if we clear the TXFERIS interrupt (by setting the TXFEIC bit) when the TX FIFO is empty, the TXFERIS interrupt does not reassert even though the TX FIFO remains empty in this situation.

When a FIFO is not assigned to a master or a slave module, the FIFO interrupt and status signals to the module are forced to a state that indicates the FIFO is empty. For example, if the TX FIFO is assigned to the master module, the status signals to the slave transmit interface indicates that the FIFO is empty.

**Note:** The FIFOs must be empty when reassigning the FIFOs for proper functionality

#### 18.3.5.1 Master Module Burst Mode

A BURST command is provided for the master module which allows a sequence of data transfers using the  $\mu$ DMA (or software, if desired) to handle the data in the FIFO. The BURST command is enabled by setting the BURST bit in the **Master Control/Status (I2CMCS)** register. The number of bytes transferred by a BURST request is programmed in the **I2C Master Burst Length (I2CMBLEN)** register and a copy of this value is automatically written to the **I2C Master Burst Count (I2CMBCNT)** register to be used as a down-counter during the BURST transfer. The bytes written to the **I2C FIFO Data (I2CFIFODATA)** register are transferred to the RX FIFO or TX FIFO depending on whether a transmit or receive is being executed. If data is NACKed during a BURST and the STOP bit is set in the **I2CMCS** register, the transfer terminates. If the STOP bit is not set, the software application must issue a repeated STOP or START when a NACK interrupt is asserted. In the case of a NACK, the **I2CMBCNT** register can be used to determine the amount of data that was transferred prior to the BURST termination. If the Address is NACKed during a transfer, then a STOP is issued.

##### **Master Module $\mu$ DMA Functionality**

When the **Master Control/Status (I2CMCS)** register is set to enable BURST and the master I<sup>2</sup>C  $\mu$ DMA channel is enabled in the **DMA Channel Map Select n (DMACHMAPn)** registers in the  $\mu$ DMA, the master control module will assert either the internal single  $\mu$ DMA request signal (dma\_sreq) or multiple  $\mu$ DMA request signal (dma\_req) to the  $\mu$ DMA. Note that there are separate dma\_req and dma\_sreq signals for transmit and receive. A single  $\mu$ DMA request (dma\_sreq) will be asserted by the Master module when the Rx FIFO has at least one data byte present in the FIFO and/or when the Tx FIFO has at least one space available to fill. The dma\_req (or Burst) signal will be asserted when Rx FIFO fill level is higher than trigger level and/or the Tx FIFO burst length remaining is less than 4 bytes and the FIFO fill level is less than trigger level. If a single transfer or BURST operation has completed, the  $\mu$ DMA sends a dma\_done signal to the master module represented by the DMATX/DMARX interrupts in the **I2CMIMR/I2CMRIS/I2CMMIS/I2CMICR** registers.

If the  $\mu$ DMA I<sup>2</sup>C channel is disabled and software is used to handle the BURST command, software can read the **FIFO Status (I2CFIFOSTAT)** Register and the **Master Burst Count (I2CMBC)** register to determine whether the FIFO needs servicing during the BURST transaction. A trigger value can be programmed in the **I2CFIFOCTL** register to allow for interrupts at various fill levels of the FIFOs.

The NACK and ARBLOST bits in the interrupt status registers can be enabled to indicate no acknowledgement of data transfer or an arbitration loss on the bus.

When the Master module is transmitting FIFO data, software can fill the Tx FIFO in advance of setting the BURST bit in the **I2CMCS** register. If the FIFO is empty when the  $\mu$ DMA is enabled for BURST mode, the `dma_req` and `dma_sreq` both assert (assuming the **I2CMLEN** register is programmed to at least 4 bytes and the Tx FIFO fill level is less than the trigger set). If the **I2CMLEN** register value is less than 4 and the Tx FIFO is not full but more than trigger level, only `dma_sreq` will assert. Single requests will be generated as required to keep the FIFO full until the number of bytes specified in the **I2CMLEN** register has been transferred to the FIFO (and the **I2CMBCOUNT** register reaches 0x0). At this point, no further requests are generated until the next BURST command is issued. If the  $\mu$ DMA is disabled, FIFOs will be serviced based on the interrupts active in the Master interrupt status registers, the FIFO trigger values shown in the **I2CFIFOSTATUS** register and completion of a BURST transfer.

When the Master module is receiving FIFO data, the Rx FIFO is initially empty and no requests are asserted. If data is read from the slave and placed into the Rx FIFO, the `dma_sreq` signal to the  $\mu$ DMA is asserted to indicate there is data to be transferred. If the Rx FIFO contains at least 4 bytes, the `dma_req` signal is also asserted. The  $\mu$ DMA will continue to transfer data out of the Rx FIFO until it has reached the amount of bytes programmed in the **I2CMLEN** register.

**Note:** The TXFEIM interrupt mask bit in the **I2CMIMR** register should be clear (masking the TXFE interrupt) when the master is performing an RX Burst from the RXFIFO and should be unmasked before starting a TX FIFO transfers.

#### 18.3.5.2 Slave Module

The slave module also has the capability to use the  $\mu$ DMA in Rx and Tx FIFO data transfers. If the Tx FIFO is assigned to the slave module and the TXFIFO bit is set in the **I2CSCSR** register, the slave module will generate a single  $\mu$ DMA request, `dma_sreq`, if the master module requests the next byte transfer. If the FIFO fill level is less than the trigger level, a  $\mu$ DMA multiple transfer request, `dma_req`, will be asserted to continue data transfers from the  $\mu$ DMA.

If the Rx FIFO is assigned to the slave module and the RXFIFO bit is set in the **I2CSCSR** register, then the slave module will generate a signal  $\mu$ DMA request, `dma_sreq`, if there is any data to be transferred. The `dma_req` signal will be asserted when the Rx FIFO has more data than the trigger level programmed by the RXTRIG bit in the **I2CFIFOCTL** register.

**Note:** Best practice recommends that an application should not switch between the **I2CSDR** register and TX FIFO or vice versa for successive transactions.

#### 18.3.6 Command Sequence Flow Charts

This section details the steps required to perform the various I<sup>2</sup>C transfer types in both master and slave mode. Refer to Table 18-5 on page 1295 for further sequence information.

##### 18.3.6.1 I<sup>2</sup>C Master Command Sequences

The figures that follow show the command sequences available for the I<sup>2</sup>C master.

Figure 18-8. Master Single TRANSMIT

Figure 18-14. Standard High Speed Mode Master Transmit

### 18.3.6.2 I<sup>2</sup>C Slave Command Sequences

Figure 18-15 on page 1284 presents the command sequence available for the I<sup>2</sup>C slave.

**Figure 18-15. Slave Command Sequence**

## 18.4 Initialization and Configuration

### 18.4.1 Configure the I<sup>2</sup>C Module to Transmit a Single Byte as a Master

The following example shows how to configure the I<sup>2</sup>C module to transmit a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I<sup>2</sup>C clock using the **RCGCI2C** register in the System Control module (see page 382).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 373). To find out which GPIO port to enable, refer to Table 25-5 on page 1569.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register (see page 754). To determine which GPIOs to configure, see Table 25-4 on page 1556.

4. Enable the I2CSDA pin for open-drain operation. See page 759.
5. Configure the PMCN fields in the **GPIOPCTL** register to assign the I<sup>2</sup>C signals to the appropriate pins. See page 771 and Table 25-5 on page 1569.
6. Initialize the I<sup>2</sup>C Master by writing the **I2CMCR** register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 100 Kbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

$$\begin{aligned} \text{TPR} &= (\text{System Clock} / (2 * (\text{SCL\_LP} + \text{SCL\_HP}) * \text{SCL\_CLK})) - 1; \\ \text{TPR} &= (20\text{MHz} / (2 * (6+4) * 100000)) - 1; \\ \text{TPR} &= 9 \end{aligned}$$

Write the **I2CMTPR** register with the value of 0x0000.0009.

8. Specify the slave address of the master and that the next operation is a Transmit by writing the **I2CMSA** register with a value of 0x0000.0076. This sets the slave address to 0x3B.
9. Place data (byte) to be transmitted in the data register by writing the **I2CMDR** register with the desired data.
10. Initiate a single byte transmit of the data from Master to Slave by writing the **I2CMCS** register with a value of 0x0000.0007 (STOP, START, RUN).
11. Wait until the transmission completes by polling the **I2CMCS** register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the **I2CMCS** register to confirm the transmit was acknowledged.

#### 18.4.2 Configure the I<sup>2</sup>C Master to High Speed Mode

To configure the I<sup>2</sup>C master to High Speed mode:

1. Enable the I<sup>2</sup>C clock using the **RCGCI2C** register in the System Control module (see page 382).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 373). To find out which GPIO port to enable, refer to Table 25-5 on page 1569.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFASEL** register (see page 754). To determine which GPIOs to configure, see Table 25-4 on page 1556.
4. Enable the I2CSDA pin for open-drain operation. See page 759.
5. Configure the PMCN fields in the **GPIOPCTL** register to assign the I<sup>2</sup>C signals to the appropriate pins. See page 771 and Table 25-5 on page 1569.
6. Initialize the I<sup>2</sup>C Master by writing the **I2CMCR** register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 3.33 Mbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```
TPR = (System Clock / (2 * (SCL_LP + SCL_HP) * SCL_CLK)) - 1;  
TPR = (80 MHz / (2 * (2 + 1) * 3330000)) - 1;  
TPR = 3
```

Write the **I2CMTPR** register with the value of 0x0000.0003.

8. To send the master code byte, software should place the value of the master code byte into the I2CMSA register and write the I2CMCS register with the following value depending on the required operation:
  - For Standard High-Speed mode, the **I2CMCS** register should be written with 0x13.
  - For Burst High-Speed mode, the **I2CMCS** register should be written with 0x50.
9. This places the I2C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the HS bit in the **I2CMCS** register.
10. The transaction is ended by setting the STOP bit in the **I2CMCS** register.
11. Wait until the transmission completes by polling the **I2CMCS** register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the **I2CMCS** register to confirm the transmit was acknowledged.

## 18.5 Register Map

Table 18-4 on page 1287 lists the I<sup>2</sup>C registers. All addresses given are relative to the I<sup>2</sup>C base address:

- I<sup>2</sup>C 0: 0x4002.0000
- I<sup>2</sup>C 1: 0x4002.1000
- I<sup>2</sup>C 2: 0x4002.2000
- I<sup>2</sup>C 3: 0x4002.3000
- I<sup>2</sup>C 4: 0x400C.0000
- I<sup>2</sup>C 5: 0x400C.1000
- I<sup>2</sup>C 6: 0x400C.2000
- I<sup>2</sup>C 7: 0x400C.3000
- I<sup>2</sup>C 8: 0x400B.8000
- I<sup>2</sup>C 9: 0x400B.9000

Note that the I<sup>2</sup>C module clock must be enabled before the registers can be programmed (see page 382). There must be a delay of 3 system clocks after the I<sup>2</sup>C module clock is enabled before any I<sup>2</sup>C module registers are accessed.

The hw\_i2c.h file in the TivaWare™ Driver Library uses a base address of 0x800 for the I<sup>2</sup>C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that TivaWare™ for C Series uses an offset between 0x000 and 0x018 with the slave base address.

**Table 18-4. Inter-Integrated Circuit (I<sup>2</sup>C) Interface Register Map**

| Offset                                   | Name          | Type | Reset       | Description                        | See page |
|------------------------------------------|---------------|------|-------------|------------------------------------|----------|
| <b>I<sup>2</sup>C Master</b>             |               |      |             |                                    |          |
| 0x000                                    | I2CMSA        | RW   | 0x0000.0000 | I2C Master Slave Address           | 1289     |
| 0x004                                    | I2CMCS        | RW   | 0x0000.0020 | I2C Master Control/Status          | 1290     |
| 0x008                                    | I2CMDR        | RW   | 0x0000.0000 | I2C Master Data                    | 1299     |
| 0x00C                                    | I2CMTPR       | RW   | 0x0000.0001 | I2C Master Timer Period            | 1300     |
| 0x010                                    | I2CMIMR       | RW   | 0x0000.0000 | I2C Master Interrupt Mask          | 1302     |
| 0x014                                    | I2CMRIS       | RO   | 0x0000.0000 | I2C Master Raw Interrupt Status    | 1305     |
| 0x018                                    | I2CMMIS       | RO   | 0x0000.0000 | I2C Master Masked Interrupt Status | 1308     |
| 0x01C                                    | I2CMICR       | WO   | 0x0000.0000 | I2C Master Interrupt Clear         | 1311     |

## **18.6 Register Descriptions (I<sup>2</sup>C Master)**

The remainder of this section lists and describes the I<sup>2</sup>C master registers, in numerical order by address offset.

**Register 1: I<sup>2</sup>C Master Slave Address (I2CMSA), offset 0x000**

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Transmit (Low).

**I2C Master Slave Address (I2CMSA)**

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000

## Register 2: I<sup>2</sup>C Master Control/Status (I2CMCS), offset 0x004

This register accesses status bits when read and control bits when written. When read, the status register indicates the state of the I<sup>2</sup>C bus controller. When written, the control register configures the I<sup>2</sup>C controller operation.

The START bit generates the START or REPEATED START condition. The STOP bit determines if the cycle stops at the end of the data cycle or continues to the next transfer cycle, which could be a repeated START. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and this register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due an error), an interrupt becomes active and the data may be read from the **I2CMDR** register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit is normally set, causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

|---|-------|----|---|--------------|
| 6 | BURST | WO | 0 | Burst Enable |
|---|-------|----|---|--------------|

Value Description

0 Burst operation is disabled.

1 The master is enabled to burst using the receive and transmit FIFOs. See field decoding in Table 18-5 on page 1295.

Note that the BURST and RUN bits are mutually exclusive.

| Bit/Field | Name  | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|-------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5         | QCMD  | WO   | 0     | Quick Command<br><br>Value    Description<br>0        Bus transaction is not a quick command.<br>1        The bus transaction is a quick command. To execute a quick command, the START, STOP and RUN bits also need to be set. After the quick command is issued, the master generates a STOP.                                                                                                        |
| 4         | HS    | WO   | 0     | High-Speed Enable<br><br>Value    Description<br>0        The master operates in Standard, Fast mode, or Fast mode plus as selected by using a value in the <b>I2CMTPR</b> register that results in an SCL frequency of 100 kbps for Standard mode, 400 kbps for Fast mode, or 1 Mbps for Fast mode plus.<br>1        The master operates in High-Speed mode with transmission speeds up to 3.33 Mbps. |
| 3         | ACK   | WO   | 0     | Data Acknowledge Enable<br><br>Value    Description<br>0        The received data byte is not acknowledged automatically by the master.<br>1        The received data byte is acknowledged automatically by the master. See field decoding in Table 18-5 on page 1295.                                                                                                                                 |
| 2         | STOP  | WO   | 0     | Generate STOP<br><br>Value    Description<br>0        The controller does not generate the STOP condition.<br>1        The controller generates the STOP condition. See field decoding in Table 18-5 on page 1295.                                                                                                                                                                                     |
| 1         | START | WO   | 0     | Generate START<br><br>Value    Description<br>0        The controller does not generate the START condition.<br>1        The controller generates the START or repeated START condition. See field decoding in Table 18-5 on page 1295.                                                                                                                                                                |

|                | 0                                                     | 1           | 0     | 0  | X   | 1    | 1     | 0   | Repeated START condition followed by N FIFO-serviced TRANSMIT operations and STOP condition (master goes to Idle state).                                  |
|                | All other combinations not listed are non-operations. |             |       |    |     |      |       |     | NOP.                                                                                                                                                      |

a. An X in a table cell indicates the bit can be 0 or 1.

- b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

### Register 3: I<sup>2</sup>C Master Data (I2CMDR), offset 0x008

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Master Transmit state and the data received when in the Master Receive state. If the BURST bit is enabled in the **I2CMCS** register, then the **I2CFIFODATA** register is used for the current data transmit or receive value and this register is ignored.

## Register 10: I<sup>2</sup>C Master Clock Low Timeout Count (I2CMCLKOCNT), offset 0x024

This register contains the upper 8 bits of a 12-bit counter that can be used to keep the timeout limit for clock stretching by a remote slave. The lower four bits of the counter are not user visible and are always 0x0.

**Note:** The Master Clock Low Timeout counter counts for the entire time SCL is held Low continuously. If SCL is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the **I2CMCLKOCNT** register and begins counting down from this value.

### I2C Master Clock Low Timeout Count (I2CMCLKOCNT)

| 7:0       | CNTL     | RW   | 0         | I <sup>2</sup> C Burst Length<br><br>This field contains the programmed length of bytes of the Burst Transaction. If BURST is enabled this register must be set to a non-zero value otherwise an error will occur. |

### Register 13: I<sup>2</sup>C Master Burst Count (I2CMBCNT), offset 0x034

When BURST is active, the value in the **I2CMLEN** register is copied into this register and decremented during the BURST transaction. This register can be used to determine the number of transfers that occurred when a BURST terminates early (as a result of a data NACK). When a BURST completes successfully, this register will contain 0.

## 18.7 Register Descriptions (I<sup>2</sup>C Slave)

The remainder of this section lists and describes the I<sup>2</sup>C slave registers, in numerical order by address offset.

**Register 14: I<sup>2</sup>C Slave Own Address (I2CSOAR), offset 0x800**

This register consists of seven address bits that identify the TM4C1290NCZAD I<sup>2</sup>C device on the I<sup>2</sup>C bus.

**Register 16: I<sup>2</sup>C Slave Data (I2CSDR), offset 0x808**

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Slave Transmit state, and the data received when in the Slave Receive state. If the RXFIFO bit or TXFIFO bit are enabled in the **I2CSCSR** register, then this register is ignored and the data value being transferred from the FIFO is contained in the **I2CFIFODATA** register.

**Note:** Best practice recommends that an application should not switch between the **I2CSDR** register and TX FIFO or vice versa for successive transactions.

**18.8 Register Descriptions (I<sup>2</sup>C Status and Control)**

The remainder of this section lists and describes the I<sup>2</sup>C status and control registers, in numerical order by address offset.

**Register 23: I<sup>2</sup>C FIFO Data (I2CFIFODATA), offset 0xF00**

The I<sup>2</sup>C FIFO Data (I2CFIFODATA) register contains the current value of the top of the RX or TX FIFO stack being used in the a transfer.

## 19 Controller Area Network (CAN) Module

Controller Area Network (CAN) is a multicast, shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically-noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths less than 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 meters).

The TM4C1290NCZAD microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CANnTX and CANnRX signals

# 19.1 Block Diagram

Figure 19-1. CAN Controller Block Diagram

# 19.2 Signal Description

The following table lists the external signals of the CAN controller and describes the function of each. The CAN controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the CAN signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 754) should be set to choose the CAN controller function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 771) to assign the CAN signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 723.

**Table 19-1. Controller Area Network Signals (212BGA)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description            |
|----------|------------|--------------------------|----------|-------------|------------------------|
| CAN0Rx   | V3<br>W10  | PA0 (7)<br>PT0 (7)       | I        | TTL         | CAN module 0 receive.  |
| CAN0Tx   | W3<br>V10  | PA1 (7)<br>PT1 (7)       | O        | TTL         | CAN module 0 transmit. |
| CAN1Rx   | A16<br>E18 | PB0 (7)<br>PT2 (7)       | I        | TTL         | CAN module 1 receive.  |

## 19.3 Functional Description

The TM4C1290NCZAD CAN controller conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

A data frame contains data for transmission, whereas a remote frame contains no data and is used to request the transmission of a specific message object. The CAN data/remote frame is constructed as shown in Figure 19-2.

**Figure 19-2. CAN Data/Remote Frame**

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These memory blocks are accessed via either of the CAN message object register interfaces.

The message memory is not directly accessible in the TM4C1290NCZAD memory map, so the TM4C1290NCZAD CAN controller provides an interface to communicate with the message memory via two CAN interface register sets for communicating with the message objects. These two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that must be processed. In general, one interface is used for transmit data and one for receive data.

### 19.3.1 Initialization

To use the CAN controller, the peripheral clock must be enabled using the **RCGC0** register (see page 385). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register (see page 385). To find out which GPIO port to enable, refer to Table 25-4 on page 1556. Set the GPIO AFSEL bits for the appropriate pins (see page 754). Configure the PMCN fields in the **GPIOCTL** register to assign the CAN signals to the appropriate pins. See page 771 and Table 25-5 on page 1569.

Software initialization is started by setting the INIT bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While INIT is set, all message transfers to and from the CAN bus are stopped and the CANnTX signal is held High. Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible while in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, label it as not valid by clearing the MSGVAL bit in the **CAN IFn Arbitration 2 (CANIFnARB2)** register. Otherwise, the whole message object must be initialized, as the fields of the message object may not have valid information, causing unexpected results. Both the INIT and CCE bits in the **CANCTL** register must be set in order to access the **CANBIT** register and the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing. To leave the initialization state, the INIT bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (indicating a bus idle condition) before it takes part in bus activities and starts message transfers. Message object initialization does not require the CAN to be in the initialization state and can be done on the fly. However, message objects should all be configured to particular identifiers or set to not valid before message transfer starts. To change the configuration of a message object during normal operation, clear the MSGVAL bit in the **CANIFnARB2** register to indicate that the message object is not valid during the change. When the configuration is completed, set the MSGVAL bit again to indicate that the message object is once again valid.

### 19.3.2 Operation

Two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**) are used to access the message objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The two sets are independent and identical and can be used to

queue transactions. Generally, one interface is used to transmit data and one is used to receive data.

Once the CAN module is initialized and the INIT bit in the **CANCTL** register is cleared, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As each message is received, it goes through the message handler's filtering process, and if it passes through the filter, is stored in the message object specified by the MNUM bit in the **CAN IFn Command Request (CANIFnCRQ)** register. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the MSK bits in the **CAN IFn Mask 1** and **CAN IFn Mask 2 (CANIFnMSKn)** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers. The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. Message objects can be used for one-time data transfers or can be permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. At the start of transmission, the appropriate TXRQST bit in the **CAN Transmission Request n (CANTXRQn)** register and the NEWDAT bit in the **CAN New Data n (CANNWDAn)** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier (MNUM) for the message object, with 1 being the highest priority and 32 being the lowest priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

Transmission can be automatically started by the reception of a matching remote frame. To enable this mode, set the RMTEN bit in the **CAN IFn Message Control (CANIFnMCTL)** register. A matching received remote frame causes the TXRQST bit to be set, and the message object automatically transfers its data or generates an interrupt indicating a remote frame was requested. A remote frame can be strictly a single message identifier, or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The UMASK bit in the **CANIFnMCTL** register enables the MSK bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The MXTD bit in the **CANIFnMSK2** register should be set if a remote frame request is expected to be triggered by 29-bit extended identifiers.

### 19.3.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if a data transfer is not occurring between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's NEWDAT bit in the **CANNWDAn** register is cleared. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the TXRQST bit in the **CANTXRQn** register is cleared. If the CAN controller is configured to interrupt on a successful transmission of a message object, (the TXIE bit in the **CAN IFn Message Control (CANIFnMCTL)** register is set), the INTPND bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is

re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

### 19.3.4 Configuring a Transmit Message Object

The following steps illustrate how to configure a transmit message object.

1. In the **CAN IFn Command Mask (CANIFnCMASK)** register:
  - Set the WRNRD bit to specify a write to the **CANIFnCMASK** register; specify whether to transfer the IDMASK, DIR, and MXTD of the message object into the **CAN IFn** registers using the MASK bit
  - Specify whether to transfer the ID, DIR, XTD, and MSGVAL of the message object into the interface registers using the ARB bit
  - Specify whether to transfer the control bits into the interface registers using the CONTROL bit
  - Specify whether to clear the INTPND bit in the **CANIFnMCTL** register using the CLRINTPND bit
  - Specify whether to clear the NEWDAT bit in the **CANNWDAn** register using the NEWDAT bit
  - Specify which bits to transfer using the DATAA and DATAB bits
2. In the **CANIFnMSK1** register, use the MSK[15:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[15:0] in this register are used for bits [15:0] of the 29-bit message identifier and are not used for an 11-bit identifier. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. For a 29-bit identifier, configure ID[15:0] in the **CANIFnARB1** register for bits [15:0] of the message identifier and ID[12:0] in the **CANIFnARB2** register for bits [28:16] of the message identifier. Set the XTD bit to indicate an extended identifier; set the DIR bit to indicate transmit; and set the MSGVAL bit to indicate that the message object is valid.
5. For an 11-bit identifier, disregard the **CANIFnARB1** register and configure ID[12:2] in the **CANIFnARB2** register for bits [10:0] of the message identifier. Clear the XTD bit to indicate a standard identifier; set the DIR bit to indicate transmit; and set the MSGVAL bit to indicate that the message object is valid.
6. In the **CANIFnMCTL** register:

- Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the TXIE bit to enable the INTPND bit to be set after a successful transmission
  - Optionally set the RMTEN bit to enable the TXRQST bit to be set on the reception of a matching remote frame allowing automatic transmission
  - Set the EOB bit for a single message object
  - Configure the DLC[3:0] field to specify the size of the data frame. Take care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
7. Load the data to be transmitted into the **CAN IFn Data (CANIFnDA1, CANIFnDA2, CANIFnDB1, CANIFnDB2)** registers. Byte 0 of the CAN data frame is stored in DATA[7:0] in the **CANIFnDA1** register.
  8. Program the number of the message object to be transmitted in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register.
  9. When everything is properly configured, set the TXRQST bit in the **CANIFnMCTL** register. Once this bit is set, the message object is available to be transmitted, depending on priority and bus availability. Note that setting the RMTEN bit in the **CANIFnMCTL** register can also start message transmission if a matching remote frame has been received.

### 19.3.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the MSGVAL bit in the **CANIFnARB2** register nor the TXRQST bits in the **CANIFnMCTL** register have to be cleared before the update.

Even if only some of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn/CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU must write all four bytes into the **CANIFnDAn/CANIFnDBn** register or the message object is transferred to the **CANIFnDAn/CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the WRNRD, DATAA and DATAB bits in the **CANIFnMSKn** register are set, followed by writing the updated data into **CANIFnDA1, CANIFnDA2, CANIFnDB1, and CANIFnDB2** registers, and then the number of the message object is written to the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. To begin transmission of the new data as soon as possible, set the TXRQST bit in the **CANIFnMSKn** register.

To prevent the clearing of the TXRQST bit in the **CANIFnMCTL** register at the end of a transmission that may already be in progress while the data is updated, the NEWDAT and TXRQST bits have to be set at the same time in the **CANIFnMCTL** register. When these bits are set at the same time, NEWDAT is cleared as soon as the new transmission has started.

### 19.3.6 Accepting Received Message Objects

When the arbitration and control field (the ID and XTD bits in the **CANIFnARB2** and the RMTEN and DLC[3:0] bits of the **CANIFnMCTL** register) of an incoming message is completely shifted into the CAN controller, the message handling capability of the controller starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the controller uses the acceptance filtering programmed through the mask bits in the **CANIFnMSKn** register and enabled using the UMASK bit in the **CANIFnMCTL** register. Each valid

message object, starting with object 1, is compared with the incoming message to locate a matching message object in the message RAM. If a match occurs, the scanning is stopped and the message handler proceeds depending on whether it is a data frame or remote frame that was received.

### 19.3.7 Receiving a Data Frame

The message handler stores the message from the CAN controller receive shift register into the matching message object in the message RAM. The data bytes, all arbitration bits, and the DLC bits are all stored into the corresponding message object. In this manner, the data bytes are connected with the identifier even if arbitration masks are used. The NEWDAT bit of the **CANIFnMCTL** register is set to indicate that new data has been received. The CPU should clear this bit when it reads the message object to indicate to the controller that the message has been received, and the buffer is free to receive more messages. If the CAN controller receives a message and the NEWDAT bit is already set, the MSGLST bit in the **CANIFnMCTL** register is set to indicate that the previous data was lost. If the system requires an interrupt on successful reception of a frame, the RXIE bit of the **CANIFnMCTL** register should be set. In this case, the INTPND bit of the same register is set, causing the **CANINT** register to point to the message object that just received a message. The TXRQST bit of this message object should be cleared to prevent the transmission of a remote frame.

### 19.3.8 Receiving a Remote Frame

A remote frame contains no data, but instead specifies which object should be transmitted. When a remote frame is received, three different configurations of the matching message object have to be considered:

**Table 19-2. Message Object Configurations**

| Configuration in <b>CANIFnMCTL</b>                                                                                                                                                                                                                                                                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 1 (set the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame to enable transmission)</li> <li>■ UMASK = 1 or 0</li> </ul>                                                                           | At the reception of a matching remote frame, the TXRQST bit of this message object is set. The rest of the message object remains unchanged, and the controller automatically transfers the data in the message object as soon as possible.                                                                                                                                                                                                                                                                                                                                                                                       |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ UMASK = 0 (ignore mask in the <b>CANIFnMSKn</b> register)</li> </ul>                                             | At the reception of a matching remote frame, the TXRQST bit of this message object remains unchanged, and the remote frame is ignored. This remote frame is disabled, the data is not transferred and nothing indicates that the remote frame ever happened.                                                                                                                                                                                                                                                                                                                                                                      |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ UMASK = 1 (use mask (MSK, MXTD, and MDIR in the <b>CANIFnMSKn</b> register) for acceptance filtering)</li> </ul> | At the reception of a matching remote frame, the TXRQST bit of this message object is cleared. The arbitration and control field (ID + XTD + RMTEN + DLC) from the shift register is stored into the message object in the message RAM, and the NEWDAT bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This mode is useful for a remote data request from another CAN device for which the TM4C1290NCZAD controller does not have readily available data. The software must fill the data and answer the frame manually. |

### 19.3.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This prioritization is separate from that of the message identifier which is enforced by the CAN bus. As a result, if message object 1 and message object 2 both have valid messages to be transmitted, message object 1 is always transmitted first regardless of the message identifier in the message object itself.

#### 19.3.10 Configuring a Receive Message Object

The following steps illustrate how to configure a receive message object.

1. Program the **CAN IFn Command Mask (CANIFnCMASK)** register as described in the “Configuring a Transmit Message Object” on page 1348 section, except that the WRNRD bit is set to specify a write to the message RAM.
2. Program the **CANIFnMSK1** and **CANIFnMSK2** registers as described in the “Configuring a Transmit Message Object” on page 1348 section to configure which bits are used for acceptance filtering. Note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. Program the **CANIFnARB1** and **CANIFnARB2** registers as described in the “Configuring a Transmit Message Object” on page 1348 section to program XTD and ID bits for the message identifier to be received; set the MSGVAL bit to indicate a valid message; and clear the DIR bit to specify receive.
5. In the **CANIFnMCTL** register:
  - Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the RXIE bit to enable the INTPND bit to be set after a successful reception
  - Clear the RMTEN bit to leave the TXRQST bit unchanged
  - Set the EOB bit for a single message object
  - Configure the DLC[3:0] field to specify the size of the data frame

Take care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
6. Program the number of the message object to be received in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. Reception of the message object begins as soon as a matching frame is available on the CAN bus.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes in the **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** register. Byte 0 of the CAN data frame is stored in DATA[7:0] in the **CANIFnDA1** register. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are received by a message object. The UMASK bit in the **CANIFnMCTL** register enables the MSK bits in the **CANIFnMSKn** register to filter which frames are received. The MXTD bit in the **CANIFnMSK2** register should be set if only 29-bit extended identifiers are expected by this message object.

### 19.3.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the **CANIFnCMSGK** register and then writes the number of the message object to the **CANIFnCRQ** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSKn**, **CANIFnARBn**, and **CANIFnMCTL**). Additionally, the NEWDAT and INTPND bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt generated by this message object.

If the message object uses masks for acceptance filtering, the **CANIFnARBn** registers show the full, unmasked ID for the received message.

The NEWDAT bit in the **CANIFnMCTL** register shows whether a new message has been received since the last time this message object was read. The MSGLSST bit in the **CANIFnMCTL** register shows whether more than one message has been received since the last time this message object was read. MSGLSST is not automatically cleared, and should be cleared by software after reading its status.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the TXRQST bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TXRQST bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

#### 19.3.11.1 Configuration of a FIFO Buffer

With the exception of the EOB bit in the **CANIFnMCTL** register, the configuration of receive message objects belonging to a FIFO buffer is the same as the configuration of a single receive message object (see "Configuring a Receive Message Object" on page 1351). To concatenate two or more message objects into a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest message object number is the first message object in a FIFO buffer. The EOB bit of all message objects of a FIFO buffer except the last one must be cleared. The EOB bit of the last message object of a FIFO buffer is set, indicating it is the last entry in the buffer.

#### 19.3.11.2 Reception of Messages with FIFO Buffers

Received messages with identifiers matching to a FIFO buffer are stored starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NEWDAT of the **CANIFnMCTL** register bit of this message object is set. By setting

NEWDAT while EOB is clear, the message object is locked and cannot be written to by the message handler until the CPU has cleared the NEWDAT bit. Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. Until all of the preceding message objects have been released by clearing the NEWDAT bit, all further messages for this FIFO buffer are written into the last message object of the FIFO buffer and therefore overwrite previous messages.

#### 19.3.11.3 Reading from a FIFO Buffer

When the CPU transfers the contents of a message object from a FIFO buffer by writing its number to the **CANIFnCRQ** register, the TXRQST and CLRINTPND bits in the **CANIFnCMSK** register should be set such that the NEWDAT and INTPEND bits in the **CANIFnMCTL** register are cleared after the read. The values of these bits in the **CANIFnMCTL** register always reflect the status of the message object before the bits are cleared. To assure the correct function of a FIFO buffer, the CPU should read out the message objects starting with the message object with the lowest message number. When reading from the FIFO buffer, the user should be aware that a new received message is placed in the message object with the lowest message number for which the NEWDAT bit of the **CANIFnMCTL** register is clear. As a result, the order of the received messages in the FIFO is not guaranteed. Figure 19-3 on page 1354 shows how a set of message objects which are concatenated to a FIFO Buffer can be handled by the CPU.

Figure 19-3. Message Objects in a FIFO Buffer

### 19.3.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. The status interrupt has the highest

priority. Among the message interrupts, the message object's interrupt with the lowest message number has the highest priority. A message interrupt is cleared by clearing the message object's INTPND bit in the **CANIFnMCTL** register or by reading the **CAN Status (CANSTS)** register. The status Interrupt is cleared by reading the **CANSTS** register.

The interrupt identifier INTID in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register reads as 0x0000. If the value of the INTID field is different from 0, then an interrupt is pending. If the IE bit is set in the **CANCTL** register, the interrupt line to the interrupt controller is active. The interrupt line remains active until the INTID field is 0, meaning that all interrupt sources have been cleared (the cause of the interrupt is reset), or until IE is cleared, which disables interrupts from the CAN controller.

The INTID field of the **CANINT** register points to the pending message interrupt with the highest interrupt priority. The SIE bit in the **CANCTL** register controls whether a change of the RXOK, TXOK, and LEC bits in the **CANSTS** register can cause an interrupt. The EIE bit in the **CANCTL** register controls whether a change of the BOFF and EWARN bits in the **CANSTS** register can cause an interrupt. The IE bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the interrupt controller. The **CANINT** register is updated even when the IE bit in the **CANCTL** register is clear, but the interrupt is not indicated to the CPU.

A value of 0x8000 in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register, indicating that either an error or status interrupt has been generated. A write access to the **CANSTS** register can clear the RXOK, TXOK, and LEC bits in that same register; however, the only way to clear the source of a status interrupt is to read the **CANSTS** register.

The source of an interrupt can be determined in two ways during interrupt handling. The first is to read the INTID bit in the **CANINT** register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and clear the message object's INTPND bit at the same time by setting the CLRINTPND bit in the **CANIFnCMSK** register. Once the INTPND bit has been cleared, the **CANINT** register contains the message number for the next message object with a pending interrupt.

### 19.3.13 Test Mode

A Test Mode is provided which allows various diagnostics to be performed. Test Mode is entered by setting the TEST bit in the **CANCTL** register. Once in Test Mode, the TX[1:0], LBACK, SILENT and BASIC bits in the **CAN Test (CANTST)** register can be used to put the CAN controller into the various diagnostic modes. The RX bit in the **CANTST** register allows monitoring of the CANnRX signal. All **CANTST** register functions are disabled when the TEST bit is cleared.

#### 19.3.13.1 Silent Mode

Silent Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames). The CAN Controller is put in Silent Mode setting the SILENT bit in the **CANTST** register. In Silent Mode, the CAN controller is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and cannot start a transmission. If the CAN Controller is required to send a dominant bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the CAN Controller monitors this dominant bit, although the CAN bus remains in recessive state.

### 19.3.13.2 Loopback Mode

Loopback mode is useful for self-test functions. In Loopback Mode, the CAN Controller internally routes the CANnTX signal on to the CANnRX signal and treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into the message buffer. The CAN Controller is put in Loopback Mode by setting the LBACK bit in the **CANTST** register. To be independent from external stimulation, the CAN Controller ignores acknowledge errors (a recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. The actual value of the CANnRX signal is disregarded by the CAN Controller. The transmitted messages can be monitored on the CANnTX signal.

### 19.3.13.3 Loopback Combined with Silent Mode

Loopback Mode and Silent Mode can be combined to allow the CAN Controller to be tested without affecting a running CAN system connected to the CANnTX and CANnRX signals. In this mode, the CANnRX signal is disconnected from the CAN Controller and the CANnTX signal is held recessive. This mode is enabled by setting both the LBACK and SILENT bits in the **CANTST** register.

### 19.3.13.4 Basic Mode

Basic Mode allows the CAN Controller to be operated without the Message RAM. In Basic Mode, The CANIF1 registers are used as the transmit buffer. The transmission of the contents of the IF1 registers is requested by setting the BUSY bit of the **CANIF1CRQ** register. The CANIF1 registers are locked while the BUSY bit is set. The BUSY bit indicates that a transmission is pending. As soon the CAN bus is idle, the CANIF1 registers are loaded into the shift register of the CAN Controller and transmission is started. When the transmission has completed, the BUSY bit is cleared and the locked CANIF1 registers are released. A pending transmission can be aborted at any time by clearing the BUSY bit in the **CANIF1CRQ** register while the CANIF1 registers are locked. If the CPU has cleared the BUSY bit, a possible retransmission in case of lost arbitration or an error is disabled.

The CANIF2 Registers are used as a receive buffer. After the reception of a message, the contents of the shift register are stored in the CANIF2 registers, without any acceptance filtering. Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read message object is initiated by setting the BUSY bit of the **CANIF2CRQ** register, the contents of the shift register are stored into the CANIF2 registers.

In Basic Mode, all message-object-related control and status bits and of the control bits of the **CANIFnCMSK** registers are not evaluated. The message number of the **CANIFnCRQ** registers is also not evaluated. In the **CANIF2MCTL** register, the NEWDAT and MSGLST bits retain their function, the DLC[3:0] field shows the received DLC, the other control bits are cleared.

Basic Mode is enabled by setting the BASIC bit in the **CANTST** register.

### 19.3.13.5 Transmit Control

Software can directly override control of the CANnTX signal in four different ways.

- CANnTX is controlled by the CAN Controller
- The sample point is driven on the CANnTX signal to monitor the bit timing
- CANnTX drives a low value
- CANnTX drives a high value

The last two functions, combined with the readable CAN receive pin CANnRX, can be used to check the physical layer of the CAN bus.

The Transmit Control function is enabled by programming the TX[1:0] field in the **CANTST** register. The three test functions for the CANnTX signal interfere with all CAN protocol functions. TX[1:0] must be cleared when CAN message transfer or Loopback Mode, Silent Mode, or Basic Mode are selected.

### 19.3.14 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

### 19.3.15 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 19-4 on page 1358): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 19-3 on page 1358). The length of the time quantum ( $t_q$ ), which is the basic time unit of the bit time, is defined by the CAN controller's input clock ( $f_{sys}$ ) and the Baud Rate Prescaler (BRP):

$$t_q = \text{BRP} / f_{sys}$$

The  $f_{sys}$  input clock is the system clock frequency as configured by the **RSCLKCFG** register (see page 269).

The Synchronization Segment Sync is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of Sync and the Sync is called the phase error of that edge.

The Propagation Time Segment Prop is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments Phase1 and Phase2 surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 19-4. CAN Bit Time

Table 19-3. CAN Protocol Ranges<sup>a</sup>

| Parameter | Range                   | Remark                                                                                                                       |
|-----------|-------------------------|------------------------------------------------------------------------------------------------------------------------------|
| BRP       | [1 .. 64]               | Defines the length of the time quantum t <sub>q</sub> . The <b>CANBRPE</b> register can be used to extend the range to 1024. |
| Sync      | 1 t <sub>q</sub>        | Fixed length, synchronization of bus input to system clock                                                                   |
| Prop      | [1 .. 8] t <sub>q</sub> | Compensates for the physical delay times                                                                                     |
| Phase1    | [1 .. 8] t <sub>q</sub> | May be lengthened temporarily by synchronization                                                                             |
| Phase2    | [1 .. 8] t <sub>q</sub> | May be shortened temporarily by synchronization                                                                              |
| SJW       | [1 .. 4] t <sub>q</sub> | May not be longer than either Phase Buffer Segment                                                                           |

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. In the **CANBIT** register, the four components TSEG2, TSEG1, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits in the SJW bit field. Table 19-4 shows the relationship between the **CANBIT** register values and the parameters.

Table 19-4. CANBIT Register Values

| CANBIT Register Field | Setting           |
|-----------------------|-------------------|
| TSEG2                 | Phase2 - 1        |
| TSEG1                 | Prop + Phase1 - 1 |
| SJW                   | SJW - 1           |
| BRP                   | BRP               |

Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync + Prop + Phase1 + Phase2] \times t_q$$

The data in the **CANBIT** register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by the BRP field) defines the length of the time quantum, the basic time

unit of the bit time; the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. In addition, the controller generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. The bit value is received or transmitted at the sample point. The information processing time (IPT) is the time after the sample point needed to calculate the next bit to be transmitted on the CAN bus. The IPT includes any of the following: retrieving the next data bit, handling a CRC bit, determining if bit stuffing is required, generating an error flag or simply going idle.

The IPT is application-specific but may not be longer than  $2 t_q$ ; the CAN's IPT is  $0 t_q$ . Its length is the lower limit of the programmed length of Phase2. In case of synchronization, Phase2 may be shortened to a value less than IPT, which does not affect bus timing.

### 19.3.16 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a required bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the required bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is Prop. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

Sync is  $1 t_q$  long (fixed), which leaves (bit time - Prop - 1)  $t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length, that is, Phase2 = Phase1, else Phase2 = Phase1 + 1.

The minimum nominal length of Phase2 has to be regarded as well. Phase2 may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of  $[0..2] t_q$ .

The length of the synchronization jump width is set to the least of 4, Phase1 or Phase2.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- $df$  = Maximum tolerance of oscillator frequency
- $f_{osc}$  = Actual oscillator frequency
- $f_{nom}$  = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq \frac{(Phase\_seg1, Phase\_seg2) \min}{2 \times (13 \times t_{bit} - Phase\_Seg2)}$$

$$df_{max} = 2 \times df \times f_{nom}$$

where:

- Phase1 and Phase2 are from Table 19-3 on page 1358
- $t_{bit}$  = Bit Time
- $df_{max}$  = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

### 19.3.16.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, and the bit rate is 1 Mbps.

$$\text{bit time} = 1 \mu\text{s} = n * t_q = 5 * t_q$$

$$t_q = 200 \text{ ns}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 200\text{E}-9 * 25\text{E}6 = 5$$

$$t_{\text{Sync}} = 1 * t_q = 200 \text{ ns}$$

\\fixed at 1 time quanta

delay of bus driver 50 ns

delay of receiver circuit 30 ns

delay of bus line (40m) 220 ns

$$t_{\text{Prop}} 400 \text{ ns} = 2 * t_q$$

\\400 is next integer multiple of  $t_q$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{TSeg1}} + t_{\text{TSeg2}} = 5 * t_q$$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{Prop}} + t_{\text{Phase 1}} + t_{\text{Phase 2}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = \text{bit time} - t_{\text{Sync}} - t_{\text{Prop}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = (5 * t_q) - (1 * t_q) - (2 * t_q)$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = 2 * t_q$$

$$t_{\text{Phase1}} = 1 * t_q$$

$$t_{\text{Phase2}} = 1 * t_q$$

\\tPhase2 = tPhase1

$$tTSeg1 = tProp + tPhase1$$

$$tTSeg1 = (2 * t_q) + (1 * t_q)$$

$$tTSeg1 = 3 * t_q$$

$$tTSeg2 = tPhase2$$

$$tTSeg2 = (\text{Information Processing Time} + 1) * t_q$$

$$tTSeg2 = 1 * t_q \quad \backslash\backslash \text{Assumes IPT}=0$$

$$tSJW = 1 * t_q \quad \backslash\backslash \text{Least of 4, Phase1 and Phase2}$$

In the above example, the bit field values for the **CANBIT** register are:

|       |                                           |
|-------|-------------------------------------------|
| TSEG2 | = TSeg2 -1<br>= 1-1<br>= 0                |
| TSEG1 | = TSeg1 -1<br>= 3-1<br>= 2                |
| SJW   | = SJW -1<br>= 1-1<br>= 0                  |
| BRP   | = Baud rate prescaler - 1<br>= 5-1<br>= 4 |

The final value programmed into the **CANBIT** register = 0x0204.

### 19.3.16.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of the CAN clock is 50 MHz, and the bit rate is 100 Kbps.

$$\text{bit time} = 10 \mu\text{s} = n * t_q = 10 * t_q$$

$$t_q = 1 \mu\text{s}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 1\text{E}-6 * 50\text{E}6 = 50$$

$$tSync = 1 * t_q = 1 \mu\text{s} \quad \backslash\backslash \text{fixed at 1 time quanta}$$

$$\text{delay of bus driver } 200 \text{ ns}$$

$$\text{delay of receiver circuit } 80 \text{ ns}$$

$$\text{delay of bus line (40m) } 220 \text{ ns}$$

$$tProp 1 \mu\text{s} = 1 * t_q \quad \backslash\backslash 1 \mu\text{s is next integer multiple of } t_q$$

$$\text{bit time} = tSync + tTSeg1 + tTSeg2 = 10 * t_q$$

$$\text{bit time} = tSync + tProp + tPhase 1 + tPhase2$$

$$tPhase 1 + tPhase2 = \text{bit time} - tSync - tProp$$

$$tPhase 1 + tPhase2 = (10 * t_q) - (1 * t_q) - (1 * t_q)$$

$$tPhase 1 + tPhase2 = 8 * t_q$$

$$tPhase1 = 4 * t_q$$

$$tPhase2 = 4 * t_q \quad \backslash\backslash tPhase1 = tPhase2$$

$$\begin{aligned}
 tTSeg1 &= tProp + tPhase1 \\
 tTSeg1 &= (1 * t_q) + (4 * t_q) \\
 tTSeg1 &= 5 * t_q \\
 tTSeg2 &= tPhase2 \\
 tTSeg2 &= (Information Processing Time + 4) * t_q \\
 tTSeg2 &= 4 * t_q \quad \quad \quad \backslash\backslash \text{Assumes IPT}=0 \\
 \\ 
 tSJW &= 4 * t_q \quad \quad \quad \backslash\backslash \text{Least of 4, Phase1, and Phase2}
 \end{aligned}$$

|       |                                            |
|-------|--------------------------------------------|
| TSEG2 | = TSeg2 -1<br>= 4-1<br>= 3                 |
| TSEG1 | = TSeg1 -1<br>= 5-1<br>= 4                 |
| SJW   | = SJW -1<br>= 4-1<br>= 3                   |
| BRP   | = Baud rate prescaler - 1<br>= 50-1<br>=49 |

The final value programmed into the **CANBIT** register = 0x34F1.

## 19.4 Register Map

Table 19-5 on page 1362 lists the registers. All addresses given are relative to the CAN base address of:

- CAN0: 0x4004.0000
- CAN1: 0x4004.1000

Note that the CAN controller clock must be enabled before the registers can be programmed (see page 385). There must be a delay of 3 system clocks after the CAN module clock is enabled before any CAN module registers are accessed.

**Table 19-5. CAN Register Map**

| Offset | Name      | Type | Reset       | Description                       | See page |
|--------|-----------|------|-------------|-----------------------------------|----------|
| 0x000  | CANCTL    | RW   | 0x0000.0001 | CAN Control                       | 1365     |
| 0x004  | CANSTS    | RW   | 0x0000.0000 | CAN Status                        | 1367     |

## 19.5 CAN Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in

the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

**Register 1: CAN Control (CANCTL), offset 0x000**

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or clearing INIT. If the device goes bus-off, it sets INIT, stopping all bus activities. Once INIT has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 \* 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after INIT is cleared, each time a sequence of 11 High bits has been monitored, a BITERROR0 code is written to the **CANSTS** register (the LEC field = 0x5), enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

**CAN Control (CANCTL)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x000

Type RW, reset 0x0000.0001

**Register 2: CAN Status (CANSTS), offset 0x004**

**Important:** This register is read-sensitive. See the register description for details.

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared when a message has been transferred (reception or transmission) without error. The unused error code 0x7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An error interrupt is generated by the BOFF and EWARN bits, and a status interrupt is generated by the RXOK, TXOK, and LEC bits, if the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPASS bit or a write to the RXOK, TXOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

**CAN Status (CANSTS)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x004

Type RW, reset 0x0000.0000

When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |  | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0). | 0x5 | Bit 0 Error |  | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1). |  | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus. | 0x6 | CRC Error |  | The CRC checksum was incorrect in the received message, indicating that the calculated value received did not match the calculated CRC of the data. | 0x7 | No Event |  | When the LEC bit shows this value, no CAN bus event was detected since this value was written to the LEC field. |
| Value     | Description                                                                                                                                                                                                                                                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | When a message is transmitted, the CAN controller monitors the data lines to detect any conflicts. When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0).                                                                                                                                                    |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1).                                                                                                                                                   |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus.                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

**Register 3: CAN Error Counter (CANERR), offset 0x008**

This register contains the error counter values, which can be used to analyze the cause of an error.

**CAN Error Counter (CANERR)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x008

Type RO, reset 0x0000.0000

## Register 4: CAN Bit Timing (CANBIT), offset 0x00C

This register is used to program the bit width and bit quantum. Values are programmed to the system clock frequency. This register is write-enabled by setting the CCE and INIT bits in the **CANCTL** register. See “Bit Time and Bit Rate” on page 1357 for more information.

| 14:12     | TSEG2    | RW   | 0x2    | Time Segment after Sample Point<br>0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x2 means that 3 (2+1) bit time quanta are defined for Phase2 (see Figure 19-4 on page 1358). The bit time quanta is defined by the BRP field.                                                                                                                                                                 |
| 11:8      | TSEG1    | RW   | 0x3    | Time Segment Before Sample Point<br>0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x3 means that 4 (3+1) bit time quanta are defined for Phase1 (see Figure 19-4 on page 1358). The bit time quanta is defined by the BRP field.                                                                                                                                                                |
| 7:6       | SJW      | RW   | 0x0    | (Re)Synchronization Jump Width<br>0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of TSEG2 or TSEG1 by the value in SJW. So the reset value of 0 adjusts the length by 1 bit time quanta.                                                                                                                       |
| 5:0       | BRP      | RW   | 0x1    | Baud Rate Prescaler<br>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum.<br>0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>BRP defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1).<br>The <b>CANBRPE</b> register can be used to further divide the bit time. |

Register 5: CAN Interrupt (CANINT), offset 0x010

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the INTID field is not 0x0000 (the default) and the IE bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the INTID field is cleared by reading the **CANSTS** register, or until the IE bit in the **CANCTL** register is cleared.

**Note:** Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

CAN Interrupt (CANINT)

**Register 6: CAN Test (CANTST), offset 0x014**

This register is used for self-test and external pin access. It is write-enabled by setting the TEST bit in the **CANCTL** register. Different test functions may be combined, however, CAN transfers are affected if the TX bits in this register are not zero.

**CAN Test (CANTST)**
