

TPLD2001 Programmable Logic Device with 18-GPIO and Selectable I²C/SPI

1 Features

- Operating characteristics
 - Extended temperature range: -40°C to 125°C
 - Wide supply voltage range: 1.71V to 5.5V
- Configurable macro-cells
 - 2-, 3-, and 4-bit lookup tables (LUT)
 - D-type flip-flops and latches with and without reset/set option
 - 8-bit shift register
 - 16-bit pattern generator
 - Counters and delay generators
 - PWM generators
 - Programmable deglitch filter or edge detector
 - Discrete analog comparators
 - Multi-channel sampling analog comparator with multi-voltage reference select
 - Voltage reference and Analog temperature sensor
 - Analog multiplexers
 - Oscillators
- Flexible digital I/O features
 - All digital signals can be routed to any GPIO
 -
 - Digital input modes: digital in with and without Schmitt-trigger, low-voltage digital in
 - Digital output modes: push-pull, open-drain NMOS, tri-state
- Development tools
 - TPLD2001 evaluation module
 - TPLD programmer
 - InterConnect Studio

2 Applications

- Wearables
- PC & notebooks
- Personal electronics
- Factory automation & control
- Gaming applications
- Communications equipment

3 Description

The TPLD2001 is part of the TI Programmable Logic Device (TPLD) family of devices that feature versatile programmable logic ICs with combinational logic, sequential logic, and analog blocks. TPLD provides an integrated, compact, low power solution to implement common system functions, such as timing delays, voltage monitors, system resets, power sequencers, I/O expanders, and more. This cost-optimized device offers a rich set of functionality in a small form factor, supports an extended temperature range from -40°C to 125°C, and operates with supply voltages ranging from 1.71V to 5.5V.

System designers can create circuits and configure the macro-cells, I/O pins, and interconnections by temporarily emulating the non-volatile memory or by permanently programming the one-time programmable (OTP) via InterConnect Studio. The TPLD2001 is supported by an extensive hardware and software ecosystem with application notes, reference designs and design examples. Visit ti.com for more information and access to design tools.

Device Information

PART NUMBER	PACKAGE ⁽¹⁾	BODY SIZE (NOM)
TPLD2001	DGS (VSSOP, 20)	5.10mm x 3.00mm
	RJY (UQFN, 20)	3.00mm x 2.00mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

Simplified Application Diagram

An IMPORTANT NOTICE at the end of this data sheet addresses availability, warranty, changes, use in safety-critical applications, intellectual property matters and other important disclaimers. ADVANCE INFORMATION for preproduction products; subject to change without notice.

Table 4-1. Pin Functions

				DESCRIPTION			
NAME	VSSOP (DGS)	UQFN (RJY)	TYPE ⁽¹⁾	Primary function	Secondary analog function (if any)	Secondary digital function (if any)	Secondary serial communications function (if any)
GPI	2	2	I	General-purpose input			VPP
GPIO1	3	3	I/O	General-purpose I/O with OE	AMUX0 A / ACMP IN2		Interface select
GPIO2	4	4	I/O	General-purpose I/O with OE	AMUX0 B / ACMP IN3		I ² C address 6
GPIO3	5	5	I/O	General-purpose I/O with OE	AMUX0 Y		I ² C address 5
GPIO4	6	6	I/O	General-purpose I/O	ACMP IN0		I ² C address 4
GPIO5	7	7	I/O	General-purpose I/O			SPI nCS / I ² C address 3
GPIO6	8	8	I/O	General-purpose I/O			SPI SCLK / I ² C SCL
GPIO7	9	9	I/O	General-purpose I/O			SPI SDI / I ² C SDA
GPIO8	10	10	I/O	General-purpose I/O			SPI SDO
GND	11	11	P	Ground			
GPIO9	12	12	I/O	General-purpose I/O	Ext. VREF IN		
GPIO10	13	13	I/O	General-purpose I/O with OE	McACMP IN0		
GPIO11	14	14	I/O	General-purpose I/O with OE	McACMP IN1		
GPIO12	15	15	I/O	General-purpose I/O with OE	McACMP IN2		
GPIO13	16	16	I/O	General-purpose I/O with OE	McACMP IN3		
GPIO14	17	17	I/O	General-purpose I/O	AMUX1 A	OSC0 Ext. CLK	
GPIO15	18	18	I/O	General-purpose I/O with OE	AMUX1 B	OSC1 Ext. CLK	
GPIO16	19	19	I/O	General-purpose I/O with OE	ACMP IN1		
GPIO17	20	20	I/O	General-purpose I/O with OE	AMUX1 Y	OSC2 Ext. CLK	
V _{CC}	1	1	P	Supply voltage			

(1) P = power, I/O = input/output, I = input

5 Specifications

5.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

			MIN	MAX	UNIT
V _{CC}	Supply voltage on V _{CC} relative to GND		-0.5	7	V
V _I	Input voltage		-0.5	7	V
V _O	Output voltage		-0.5	7	V
I _{IOK}	Input-output clamp current	V _{IO} < 0	-50		mA
I _O	Continuous output current	V _O = 0 to V _{CC}	-50	50	mA
I _{DC}	Maximum average or DC current (through each pin)	Push-pull 1X		12	mA
		Push-pull 2X		17	
		Open-drain NMOS 1X		18	
		Open-drain NMOS 2X		28	
		Open-drain NMOS 4X		45	
T _J	Junction temperature		150		°C
T _{stg}	Storage temperature		-65	150	°C

- (1) Operation outside the *Absolute Maximum Ratings* may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under *Recommended Operating Conditions*. If used outside the *Recommended Operating Conditions* but within the *Absolute Maximum Ratings*, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.

5.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins ⁽¹⁾	±2000	V
		Charged device model (CDM), per ANSI/ESDA/JEDEC specification JS-002, all pins ⁽²⁾	±1500	

- (1) JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.

- (2) JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

5.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

			V _{CC}	MIN	MAX	UNIT
V _{CC}	Supply voltage			1.71	5.5	V
V _I	Input voltage			0	5.5	V
V _O	Output voltage			0	5.5	V
V _{IH}	High-level input voltage	Logic input	1.71V to 5.5V	(0.7 × V _{CC})		V
			1.8V ± 0.09V	0.90		
		Low-voltage logic input	3.3V ± 0.3V	1.08		
			5V ± 0.5V	1.22		
V _{IH}	High-level input voltage	I ² C SCL, SDA pins SPI SDI, SCLK, nCS	1.71V to 5.5V	(0.7 × V _{CC})		V
V _{IL}	Low-level input voltage	Logic input	1.71V to 5.5V		(0.3 × V _{CC})	V
			1.8V ± 0.09V		0.47	
		Low-voltage logic input	3.3V ± 0.3V		0.52	
			5V ± 0.5V		0.56	
V _{IL}	Low-level input voltage	I ² C SCL, SDA pins SPI SDI, SCLK, nCS	1.71V to 5.5V		(0.3 × V _{CC})	V
F _(EXT_OSC)	External Oscillator Frequency	Logic input or Logic input with Schmitt trigger	1.8V ± 0.09V		10	MHz
			3.3V ± 0.3V		25	
			5V ± 0.5V		25	
		Low-voltage logic input	1.8V ± 0.09V		10	MHz
			3.3V ± 0.3V		10	
			5V ± 0.5V		10	
T _A	Ambient temperature			-40	125	°C

5.4 Thermal Information

PACKAGE	PINS	THERMAL METRIC ⁽¹⁾						UNIT
		R _{θJA}	R _{θJC(top)}	R _{θJB}	Ψ _{JT}	Ψ _{JB}	R _{θJC(bot)}	
DGS (VSSOP)	20	92.9	35.7	49.7	1.3	49.3		°C/W
RJY (UQFN)	20	108.3	39.4	50.7	1.0	50.7		°C/W

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics application report](#).

5.5 Electrical Characteristics

over operating free-air temperature range (unless otherwise noted)

PARAMETER		TEST CONDITIONS	V _{CC}	MIN	TYP	MAX	UNIT
Supply and Power-on Reset							
V _{PORR}	Power-on reset voltage, V _{CC} rising	V _I = V _{CC} or GND, I _O = 0		1.27	1.39	1.39	V
V _{PORF}	Power-on reset voltage, V _{CC} falling	V _I = V _{CC} or GND, I _O = 0		1.14	1.26	1.26	V
t _{SU}	Startup time	from V _{CC} rising past V _{PORR} to GPO becoming active			0.76		ms
V _{PP}	Programming voltage			7.5	8	8	V
Digital IO							
V _{T+}	Positive-going input threshold voltage	Logic Input with Schmitt Trigger		1.8V ± 0.09V	0.94	1.27	V
				3.3V ± 0.3V	1.55	2.17	
				5V ± 0.5V	2.21	3.19	
V _{T-}	Negative-going input threshold voltage	Logic Input with Schmitt Trigger		1.8V ± 0.09V	0.58	0.94	V
				3.3V ± 0.3V	1.1	1.79	
				5V ± 0.5V	1.63	2.7	
V _{HYS}	Schmitt-Trigger hysteresis (V _{T+} - V _{T-})	Logic Input with Schmitt Trigger		1.8V ± 0.09V	0.08	0.36	V
				3.3V ± 0.3V	0.15	0.66	
				5V ± 0.5V	0.22	1.00	
V _{OH}	High-level output voltage	Push-pull 1X	I _{OH} = -100µA	1.8V ± 0.09V	1.68		V
		Push-pull 2X			1.69		
		Push-pull 1X	I _{OH} = -3mA	3.3V ± 0.3V	2.47		
		Push-pull 2X			2.63		
		Push-pull 1X	I _{OH} = -5mA	5V ± 0.5V	3.84		
		Push-pull 2X			4.02		
V _{OH}	High-level output voltage	SPI SDO	I _{OH} = -2mA	1.71V to 5.5V	(0.8 × V _{CC})		V
V _{OL}	Low-level output voltage	Push-pull 1X	I _{OL} = 100µA	1.8V ± 0.09V		0.01	V
		Push-pull 2X				0.01	
		Open-drain NMOS 1X				0.01	
		Open-drain NMOS 2X				0.01	
		Push-pull 1X	I _{OL} = 3mA	3.3V ± 0.3V		0.1	
		Push-pull 2X				0.1	
		Open-drain NMOS 1X				0.1	
		Open-drain NMOS 2X				0.1	
		Push-pull 1X	I _{OL} = 5mA	5V ± 0.5V		0.12	
		Push-pull 2X				0.12	
		Open-drain NMOS 1X				0.12	
		Open-drain NMOS 2X				0.12	

5.5 Electrical Characteristics (continued)

over operating free-air temperature range (unless otherwise noted)

PARAMETER		TEST CONDITIONS	V _{CC}	MIN	TYP	MAX	UNIT	
V _{OL}	Low-level output voltage	I ² C SCL, SDA pins (Open-drain NMOS 4X)	I _{OL} = 3mA	V _{CC} > 2V		0.4	V	
		I ² C SCL, SDA pins (Open-drain NMOS 4X)	I _{OL} = 2mA	V _{CC} ≤ 2V		(0.2 × V _{CC})		
		SPI SDO pin	I _{OL} = 2mA	1.71V to 5.5V		(0.2 × V _{CC})		
I _{OL}	Low-level output current	I ² C SCL, SDA pins (Standard mode, Fast mode)	V _{OL} = 0.4V	1.71V to 5.5V	3		mA	
		I ² C SCL, SDA pins (Fast mode Plus)			20			
I _I	Input leakage current	All pins	V _I = V _{CC}	1.71V to 5.5V		±1	μA	
			V _I = GND			±1		
I _{OZ}	Off-state (high-Z state) output current		V _O = 0 to 5.5V	1.71V to 5.5V		±1	μA	
I _{off}	Input/output power-off leakage current		V _I or V _O = 5.5V	0V		±5	μA	
F _{OUT}	Max output frequency ⁽¹⁾	All IOs Push-pull 1X or Push-pull 2X	C _L = 15pF	1.8V ± 0.09V		8	MHz	
				3.3V ± 0.3V		8	MHz	
				5V ± 0.5V		8	MHz	
F _{OUT}	Max output frequency ⁽¹⁾	IO14, IO15, IO17 only Push-pull 1X or Push-pull 2X	C _L = 15pF	1.8V ± 0.09V		10	MHz	
				3.3V ± 0.3V		12	MHz	
				5V ± 0.5V		12	MHz	
R _{pu(int)}	Internal pull-up resistance				1		MΩ	
					100		kΩ	
					10		kΩ	
R _{pd(int)}	Internal pull-down resistance				1		MΩ	
					100		kΩ	
					10		kΩ	
C _I	Input pin capacitance	each input pin	V _I = V _{CC} or GND	1.71V to 5.5V		4	10	pF
C _I	Input pin capacitance	I ² C SCL pin SPI SDI, SCK, nCS pins	V _I = V _{CC} or GND	1.71V to 5.5V		4	10	pF
C _{IO}	Input-output pin capacitance	each I/O pin	V _{IO} = V _{CC} or GND	1.71V to 5.5V		4	10	pF
C _{IO}	Input-output pin capacitance	I ² C SDA pin	V _{IO} = V _{CC} or GND	1.71V to 5.5V		4	10	pF

Analog Comparator - Discrete Analog Comparator

5.5 Electrical Characteristics (continued)

over operating free-air temperature range (unless otherwise noted)

PARAMETER			TEST CONDITIONS	V _{CC}	MIN	TYP	MAX	UNIT	
t _{start}	Start time	ACMP power on delay	Bandgap force on, Oscillator force on	1.71V to 5.5V	110	110	110	μs	
			Bandgap force on, Oscillator auto on						
			Bandgap auto on, Oscillator force on						
			Bandgap auto on, Oscillator auto on						
V _{AI}	Input voltage	Positive input		1.71V to 5.5V	0	V _{CC}		V	
		Negative input			0	2.016			
V _{offset}	Input offset voltage	T _A = 25°C	V _{HYS} = 0mV, Gain = 1, VREF = 32mV to 1504mV	1.71V to 5.5V	-12	12		mV

5.5 Electrical Characteristics (continued)

over operating free-air temperature range (unless otherwise noted)

PARAMETER		TEST CONDITIONS	V _{CC}	MIN	TYP	MAX	UNIT	
r_{on}	ON-state switch resistance	$-40^{\circ}\text{C} < T_A \leq 125^{\circ}\text{C}$	$V_I = 0\text{V}, I_O = 4\text{mA}$	$1.8\text{V} \pm 0.09\text{V}$		35	Ω	
			$V_I = 1.71\text{V}, I_O = -4\text{mA}$			35		
			$V_I = 0\text{V}, I_O = 8\text{mA}$	$2.5\text{V} \pm 0.2\text{V}$		32.5		
			$V_I = 2.3\text{V}, I_O = -8\text{mA}$			32.5		
			$V_I = 0\text{V}, I_O = 24\text{mA}$	$3.3\text{V} \pm 0.3\text{V}$		30		
			$V_I = 3\text{V}, I_O = -24\text{mA}$			30		
			$V_I = 0\text{V}, I_O = 30\text{mA}$	$5\text{V} \pm 0.5\text{V}$		25		
			$V_I = 2.4\text{V}, I_O = -30\text{mA}$			25		
			$V_I = 4.5\text{V}, I_O = -30\text{mA}$			25		
r_{range}	ON-state switch resistance over signal range	$0 \leq V_A, V_B \leq V_{CC}$ $-40^{\circ}\text{C} < T_A \leq 125^{\circ}\text{C}$	$I_O = -4\text{mA}$	$1.8\text{V} \pm 0.09\text{V}$		205	Ω	
			$I_O = -8\text{mA}$	$2.5\text{V} \pm 0.2\text{V}$		75		
			$I_O = -24\text{mA}$	$3.3\text{V} \pm 0.3\text{V}$		35		
			$I_O = -30\text{mA}$	$5\text{V} \pm 0.5\text{V}$		25		
Δr_{on}	Difference of ON-state resistance between switches	$V_A, V_B = 1.15\text{V}$ $-40^{\circ}\text{C} < T_A \leq 125^{\circ}\text{C}$	$I_O = -4\text{mA}$	$1.8\text{V} \pm 0.09\text{V}$		0.5	Ω	
			$I_O = -8\text{mA}$	$2.5\text{V} \pm 0.2\text{V}$		0.3		
			$I_O = -24\text{mA}$	$3.3\text{V} \pm 0.3\text{V}$		0.3		
			$I_O = -30\text{mA}$	$5\text{V} \pm 0.5\text{V}$		0.2		
$r_{on(\text{flat})}$	ON-state resistance flatness	$0 \leq V_A, V_B \leq V_{CC}$ $-40^{\circ}\text{C} < T_A \leq 125^{\circ}\text{C}$	$I_O = -4\text{mA}$	$1.8\text{V} \pm 0.09\text{V}$		110	Ω	
			$I_O = -8\text{mA}$	$2.5\text{V} \pm 0.2\text{V}$		40		
			$I_O = -24\text{mA}$	$3.3\text{V} \pm 0.3\text{V}$		10		
			$I_O = -30\text{mA}$	$5\text{V} \pm 0.5\text{V}$		2		
I_{off}	OFF-state switch leakage current		$0 \leq V_I, V_O \leq V_{CC}$	$1.71\text{V} \text{ to } 5.5\text{V}$		± 7.5	μA	
$I_{S(on)}$	ON-state switch leakage current		$V_I = V_{CC} \text{ or GND}, V_O = \text{Open}$	5.5V		± 0.1	± 2.5	μA
Cio(off)	Switch input/output capacitance	A, B		5V		9.5	pF	
Cio(on)	Switch input/output capacitance	A, B		5V		20	pF	
		Y				20		

(1) Open drain switching performance will be limited by pull-up resistors used

(1) t_{pd} is the slower of t_{PLH} or t_{PHL} . The delay is the calculated RC time constant of the typical ON-state resistance of the switch and the specified load capacitance when driven by an ideal voltage source (zero output impedance).

(2) t_{en} is the slower of t_{PZL} or t_{PZH} .

(3) t_{dis} is the slower of t_{PLZ} or t_{PHZ} .

t_{ocf}	I^2C output fall time	10-pF to 400-pF bus (Sm/Fm) 10-pF to 550-pF bus (Fm+)		300		300		120	ns
t_{buf}	I^2C bus free time between stop and start			4.7		1.3		0.5	μs
t_{sts}	I^2C start or repeated start condition setup			4.7		0.6		0.26	μs
t_{sth}	I^2C start or repeated start condition hold			4		0.6		0.26	μs
t_{sps}	I^2C stop condition setup			4		0.6		0.26	μs
$t_{vd(data)}$	Valid data time	SCL low to SDA output valid		3.45		0.9		0.45	μs
$t_{vd(ack)}$	Valid data time of ACK condition	ACK signal from SCL low to SDA (out) low		3.45		0.9		0.45	μs
C_b	I^2C bus capacitive load			400		400		550	pF

5.9 SPI Timing Requirements

over operating free-air temperature range (unless otherwise noted)

PARAMETER		TEST CONDITION	MIN	NOM	MAX	UNIT
f_{SCLK}	SCLK, SPI clock frequency				4	MHz
t_{SCLK}	SCLK, SPI clock period		250			ns
t_R	SDI, nCS, and SCLK signals rise time			40		ns
t_F	SDI, nCS, and SCLK signals fall time			40		ns
t_{SCLKH}	SCLK High time		125			ns
t_{SCLKL}	SCLK Low time		125			ns
t_{NCS_SU}	nCS setup time before rising edge of SCLK		100			ns
t_{NCS_HOLD}	nCS hold time after falling edge of SCLK		100			ns
t_{NCS_DIS}	nCS disable time		50			ns
t_{SDI_SU}	SDI setup time before rising edge of SCLK		50			ns
t_{SDI_HOLD}	SDI hold time after rising edge of SCLK		50			ns
t_{SDO_VALID}	Time from falling edge of SCLK to next SDO data				80	ns
t_{SDOR}	SDO rise time			40		ns
t_{SDOF}	SDO fall time			40		ns

6 Parameter Measurement Information

- A. C_L include probe and jig capacitance.
- B. All inputs are supplied by generators having the following characteristics: PRR $\leq 10 \text{ MHz}$, $Z_O = 50 \Omega$, $t_r/t_f \leq 30 \text{ ns}$.
- C. All parameters and waveforms are not applicable to all devices.

Figure 6-1. I²C Interface Load Circuit and Voltage Waveforms

7 Detailed Description

7.1 Overview

The TPLD2001 is part of the TI programmable logic device (TPLD) family of devices that feature versatile programmable logic ICs with combinational logic, sequential logic, and analog blocks to provide an integrated, compact, low power solution to implement common system functions.

The TPLD2001 has seventeen GPIOs and one GPI that can be configured as digital inputs, digital outputs, digital input/outputs, or analog input/outputs.

The TPLD2001 has a system of interconnects, further referred to as the connection mux, to configure the routing of internal macro-cells and I/O pins. Each connection mux input is hardwired to a specific digital macro-cell output, such as digital I/O, lookup tables, and analog comparator outputs. The connection mux allows each of the digital inputs to only connect to one output so that bus contention does not occur.

The TPLD2001 features the following macro-cells:

- Fourteen configurable use logic blocks to implement combinational or sequential logic
 - Three selectable 2-bit LUT or D flip-flop/latch
 - One selectable 2-bit LUT or Pattern generator
 - Two selectable 3-bit LUT or D flip-flop/latch
 - Four selectable 3-bit LUT or D flip-flop/latch or shift register
 - Four selectable 4-bit LUT or D flip-flop/latch
- Six configurable logic and timing blocks
 - Four 3-bit LUT or D flip-flop/latch and/or 8-bit counter
 - Two 3-bit LUT or D flip-flop/latch and/or 16-bit counter
- Two programmable deglitch filter or edge detector
- One deglitch filter or edge detector
- One 8-state state machine, asynchronous or synchronous mode
- Four 8-bit counter/finite state machine
- Four PWM generators
- One watchdog timer
- Four discrete analog comparators
- One multi-channel analog comparator with integrated sampling engine and multi-voltage reference selection
- Internal voltage reference
- Analog temperature sensor
- Two break-before-make analog multiplexers
- Three oscillators: 2kHz, 2MHz, and 25MHz
- One serial communication: selectable between I²C or SPI

InterConnect Studio enables a simple drag-and-drop interface to build custom circuit designs and configure the macro-cells, I/O pins, and interconnections by writing the one-time programmable (OTP) non-volatile memory. In addition to circuit creation, InterConnect Studio has the ability to simulate digital and analog functionality to verify designs and provide a typical power consumption estimate. Once circuit designs are finalized, the OTP can be written to and locked to prevent readback of its contents.

7.2 Functional Block Diagram

Figure 7-1. TPLD2001 Functional Block Diagram

7.3 Feature Description

7.3.1 I/O Pins

TPLD2001 has one input and seventeen multifunction I/O pins. GPIO pins can function as either a user defined input, output, or a special function.

7.3.1.1 Input Modes

The following options are available when configuring pins as an input:

- Digital input without Schmitt-trigger
- Digital input with Schmitt-trigger
- Low-voltage digital input

The low-voltage digital input has lower V_{IH}/V_{IL} specifications than the digital input without Schmitt trigger. This allows for up-translation from any voltage domain lower than V_{CC} that meets the low-voltage digital input V_{IH} and V_{IL} specifications.

In addition to digital input options, several IOs can serve a special function. Three IOs can be used as an external oscillator input.

- IO14: OSC0 external clock
- IO15: OSC1 external clock
- IO17: OSC2 external clock

Several IOs can also be configured to serve as analog inputs to the internal analog comparators.

- IO4: ACMP IN0
- IO16: ACMP IN1
- IO1: ACMP IN2
- IO2: ACMP IN3
- IO9: External VREF IN
- IO10: McACMP IN0
- IO11: McACMP IN1
- IO12: McACMP IN2
- IO13: McACMP IN3

Three IOs can also be configured as bidirectional analog pins for the internal break-before-make analog multiplexer.

- IO1: AMUX0 A
- IO2: AMUX0 B
- IO3: AMUX0 Y
- IO14: AMUX1 A
- IO15: AMUX1 B
- IO17: AMUX1 Y

7.3.1.2 Output Modes

The following options are available with programmable drive strengths when configuring pins as an output:

- Push-pull output
- Open-drain NMOS output

7.3.1.3 Pull-Up or Pull-Down Resistors

All I/O pins have the option of user-selectable resistors that can be connected to the pin structure. The selectable values on these resistors are 10k Ω , 100k Ω and 1M Ω . The internal resistors can be configured as either pull-up or pull-down. When designing in InterConnect Studio, any pin left unused in a design are configured with a 1M Ω pull-down by default. Furthermore, following a power-on event, all ports are in a Hi-Z state until the power-on reset sequence has completed.

Table 7-1. Pin Configuration Options

GPIO	IO selection	OE	IO options	Resistor	Resistor value (Ω)
IN0	Pin not used	—	—	Pull Down	1 M
	Digital input	0	Digital in without Schmitt trigger	Floating	—
			Digital in with Schmitt trigger	Pull Down	10 k
IO6, IO7	Digital input	0	Low voltage digital input	Pull Up	100 k
					1 M
IO1, IO2, IO3, IO10, IO11, IO12, IO13, IO15, IO16, IO17	Pin not used	—	—	Pull Down	1 M
	Digital input	0	Digital in without Schmitt trigger	Floating	—
			Digital in with Schmitt trigger	Pull Down	10 k
IO6, IO7	Digital output	1	Low voltage digital input	Pull Up	100 k
					1 M
IO1, IO2, IO3, IO10, IO11, IO12, IO13, IO15, IO16, IO17	Pin not used	—	—	Pull Down	1 M
	Digital input	0	Digital in without Schmitt trigger	Floating	—
			Digital in with Schmitt trigger	Pull Down	10 k
IO6, IO7	Digital output	1	Low voltage digital input	Pull Up	100 k
					1 M
IO6, IO7	Digital input/output	0	Push pull (1X, 2X)	Floating	—
			Open drain NMOS (1X, 4X)	Pull Down	10 k
				Pull Up	100 k
IO6, IO7	Digital input/output	1			1 M
IO6, IO7	Analog input/output	—	Push pull (1X, 2X)	Floating	—
			Open drain NMOS (1X, 2X)	Pull Down	10 k
			3-state output (1X, 2X)	Pull Up	100 k
IO6, IO7	Analog input/output	—			1 M

Table 7-1. Pin Configuration Options (continued)

GPIO	IO selection	OE	IO options	Resistor	Resistor value (Ω)
IO5, IO8	Pin not used	—	—	Pull Down	1 M
	Digital input	0	Digital in without Schmitt trigger	Floating	—
			Digital in with Schmitt trigger	Pull Down	10 k
			Low voltage digital input	Pull Up	100 k
					1 M
	Digital output	1	Push pull (1X, 2X)	Floating	—
			Open drain NMOS (1X, 2X)	Pull Down	10 k
	Digital input/output	0	Digital in without Schmitt trigger	Floating	—
			Digital in with Schmitt trigger	Pull Down	10 k
			Low voltage digital input	Pull Up	100 k
		1	Push pull (1X, 2X) Open drain NMOS (1X, 2X)		1 M
IO4, IO9, IO14	Pin not used	—	—	Pull Down	1 M
	Digital input	0	Digital in without Schmitt trigger	Floating	—
			Digital in with Schmitt trigger	Pull Down	10 k
			Low voltage digital input	Pull Up	100 k
	Digital output	1	Push pull (1X, 2X)	Floating	—
			Open drain NMOS (1X, 2X)	Pull Down	10 k
	Analog input/output	—	Analog input/output	Floating	—
				Pull Down	10 k
				Pull Up	100 k
					1 M

Note

When using an IO with output-enable (OE) controlled from the CMX, configured as a Digital output with 3-state output, it is recommended to configure the input mode to Digital in with Schmitt trigger.

7.3.2 Connection Mux

The connection mux is used to create the internal routing for internal functions of the device once it is programmed. The registers are programmed from the one-time programmable memory (OTP).

The output of each functional macro-cell within the TPLD2001 has a specific digital bit code assigned to it that is either set to active “High” or inactive “Low” based on the design that is created. Once the 2048 register bits within the TPLD2001 are programmed a fully custom circuit will be created.

The connection mux has 83 inputs and 157 outputs. Each of the 83 inputs to the connection mux is hard-wired to a particular source macro-cell, including I/O pins, LUTs, analog comparators, other digital resources and V_{CC} and GND. The input to a digital macro-cell uses a 7-bit register to select one of these 83 input lines.

Table 7-2. Connection mux input table

Connection Mux Input	Connection Mux Input Signal	Mux Decode						
		6	5	4	3	2	1	0
0	GND	0	0	0	0	0	0	0

7.3.3 Configurable Use Logic Blocks

Combinational logic is supported via Look-up Tables (LUTs) within the TPLD2001. Inputs and outputs for the combination function macro-cells are configured from the connection mux with specific logic functions being defined by the state of OTP bits.

The TPLD2001 has sixteen configurable use logic blocks (macro-cells) that can serve as a combinational or sequential logic function. In each case, they can serve as a Look-up Table (LUT), or as another logic or timing function. See the list below for the functions that can be implemented in these logic blocks:

- Three selectable 2-input LUT or D flip-flop or latch (DFF/L)
- One selectable 2-input LUT or pattern generator (PGEN)
- Two selectable 3-input LUT or DFF/L with reset/set
- Four selectable 3-input LUT or DFF/L or Shift register (SR)
- Four selectable 4-input LUT or DFF/L with reset/set

7.3.3.1 2-Bit LUT or D Flip-Flop/Latch macro-cell

This configurable logic block can serve as either a 2-bit LUT or as a D flip-flop or latch.

Figure 7-2. 2-bit LUT or DFF/Latch Block Diagram

7.3.3.1.1 2-Bit LUT

When used to implement LUT functions, the 2-bit LUT take in two input signals from the connection mux and produce a single output, which goes back into the connection mux. These LUTs can be configured to any 2-input user defined function, including the following standard digital logic functions (AND, NAND, OR, NOR, XOR, XNOR).

When programmed for a LUT function, each macro-cell uses a 4-bit register to define their output function.

[Table 7-4](#) shows the truth tables for the 2-bit LUT.

Table 7-4. 2-bit LUT Truth Table

IN1	IN0	OUT
0	0	
0	1	
1	0	
1	1	

7.3.3.1.2 D Flip-Flop/Latch

When used to implement a sequential logic element, the two input signals from the connection mux go to the data (D) and clock (CLK) inputs of the flip-flop or latch, with the output going back to the connection mux. This macro-cell has initial state parameters as well as clock and output polarity parameters that can be configured.

The operation of the D flip-flop/latch will follow the functional descriptions below:

- The clock polarity is configurable and can be set to non-inverted (CLK) or inverted (nCLK).
 - DFF with CLK: CLK is rising edge triggered, then $Q = D$; otherwise Q will not change.
 - DFF with nCLK: CLK is falling edge triggered, then $Q = D$; otherwise Q will not change.
 - Latch with CLK: when CLK is Low, then $Q = D$; otherwise Q remains its previous value (input D has no effect on the output, when CLK is High).
 - Latch with nCLK: when CLK is High, then $Q = D$; otherwise Q remains its previous value (input D has no effect on the output, when CLK is Low).
- The output polarity is configurable and can be set to non-inverted (Q) or inverted (nQ).

Table 7-5 and Table 7-6 show the truth tables for the D flip-flop and D latch, respectively.

Table 7-5. D Flip-Flop Truth Table

CLKPOL	CLK	D	Q	nQ
0	↓	0	Q_0	nQ_0
	↑	0	0	1
	↓	1	Q_0	nQ_0
	↑	1	1	0
1	↓	0	0	1
	↑	0	Q_0	nQ_0
	↓	1	1	0
	↑	1	Q_0	nQ_0

Table 7-6. D Latch Truth Table

CLKPOL	CLK	D	Q	nQ
0	0	0	0	1
	1	0	Q_0	nQ_0
	0	1	1	0
	1	1	Q_0	nQ_0
1	0	0	Q_0	nQ_0
	1	0	0	1
	0	1	Q_0	nQ_0
	1	1	1	0

7.3.3.2 2-Bit LUT or Pattern Generator macro-cell

This configurable use logic block can serve as either a 2-bit LUT or as a Pattern generator.

Figure 7-3. 2-bit LUT or Pattern Generator Block Diagram

7.3.3.2.1 2-Bit LUT

When used to implement LUT functions, the 2-bit LUT take in two input signals from the connection mux and produce a single output, which goes back into the connection mux. These LUTs can be configured to any 2-input user defined function, including the following standard digital logic functions (AND, NAND, OR, NOR, XOR, XNOR).

When programmed for a LUT function, each macro-cell uses a 4-bit register to define their output function.

[Table 7-7](#) shows the truth tables for the 2-bit LUT.

Table 7-7. 2-bit LUT Truth Table

IN1	IN0	OUT
0	0	
0	1	
1	0	
1	1	

7.3.3.2.2 Pattern Generator

When configured as a Pattern generator, the two input signals from the connect mux go to the reset (nRST/RST) and clock (CLK) inputs of the pattern generator, with the output going back to the connection mux. This macro-cell has pattern size, bit pattern, and reset signal polarity parameters that can be configured to generate up to a 16-bit pattern that is clocked out continually on the rising edge of the CLK input as long as the macro-cell is not in reset. While in reset, the macro-cell will continually output the first bit of the programmed bit pattern.

Figure 7-4. Pattern generator output timing diagram example (SIZE = 3, PATTERN = 011, Low level RST)

Figure 7-5. Pattern generator output timing diagram example (SIZE = 3, PATTERN = 100, Low level RST)

The output pattern can be updated in-system using the User Registers. It is recommended to put the pattern generator in a reset state when updating the pattern registers to ensure glitch-free loading of the data.

7.3.3.3 3-Bit LUT or D Flip-Flop/Latch with Reset/Set macro-cell

This configurable use logic block can serve as either a 3-bit LUT or as a D flip-flop or latch with a reset or set.

Figure 7-6. 3-bit LUT or DFF/Latch with nRST/nSET Block Diagram

7.3.3.3.1 3-Bit LUT

When used to implement LUT functions, the 3-bit LUTs each take in three input signals from the connection mux and produce a single output, which goes back into the connection mux. These LUTs can be configured to any 3-input user defined function, including the following standard digital logic functions (AND, NAND, OR, NOR, XOR, XNOR).

When programmed for a LUT function, each macro-cell uses an 8-bit register to define their output function.

Table 7-8 shows truth tables for the 3-bit LUT.

Table 7-8. 3-bit LUT Truth Table

IN2	IN1	IN0	OUT
0	0	0	
0	0	1	
0	1	0	
0	1	1	
1	0	0	
1	0	1	
1	1	0	
1	1	1	

7.3.3.3.2 D Flip-Flop/Latch with Reset/Set

When used to implement a sequential logic element, the three input signals from the connection mux go to the data (D), clock (CLK), and reset/set (nRST/nSET) inputs for the flip-flop or latch, with the output going back to the connection mux. This macro-cell has user-configurable initial state, clock polarity, reset/set polarity, output select, and output polarity parameters.

The operation of the D flip-flop/latch will follow the functional descriptions below:

- The clock polarity is configurable and can be set to non-inverted (CLK) or inverted (nCLK).
 - DFF with CLK: CLK is rising edge triggered, then Q = D; otherwise Q will not change.
 - DFF with nCLK: CLK is falling edge triggered, then Q = D; otherwise Q will not change.
 - Latch with CLK: when CLK is Low, then Q = D; otherwise Q remains its previous value (input D has no effect on the output, when CLK is High).
 - Latch with nCLK: when CLK is High, then Q = D; otherwise Q remains its previous value (input D has no effect on the output, when CLK is Low).
- These DFF/Latches have an option for both an active-low and active-high reset/set:
 - nRST: If High, then the DFF/Latch is in normal operation. If Low, then Q is reset to 0.
 - RST: If Low, then the DFF/Latch is in normal operation. If High, then Q is reset to 0.
 - nSET: If High, then the DFF/Latch is in normal operation. If Low, then Q is set to 1.
 - SET: If Low, then the DFF/Latch is in normal operation. If High, then Q is set to 1.
- If reset/set is not desired, users may set the polarity to active-low and connect this input to V_{CC} or a constant High source.
- These DFF/Latches have the option to further isolate the output from the input with the use of a second DFF/Latch and sampling on the falling edge of CLK and enabling the "Dual Stage DFF" option.
- The output polarity is configurable and can be set to non-inverted (Q) or inverted (nQ).

Table 7-9 and Table 7-10 show the truth tables for the D flip-flop and D latch with an active-low reset/set, respectively.

Table 7-9. D Flip-Flop with nRST/nSET Truth Table

7.3.3.4 3-Bit LUT or D Flip-Flop/Latch or Shift Register macro-cell

This configurable use logic block can serve as either a 3-bit LUT or as a D flip-flop or latch with a reset or set or an 8-bit Shift register.

Figure 7-7. 3-bit LUT or DFF/Latch with nRST/nSET or 8-bit SISO Shift Register Block Diagram

7.3.3.4.1 3-Bit LUT

When used to implement LUT functions, the 3-bit LUTs each take in three input signals from the connection mux and produce a single output, which goes back into the connection mux. These LUTs can be configured to any 3-input user defined function, including the following standard digital logic functions (AND, NAND, OR, NOR, XOR, XNOR).

When programmed for a LUT function, each macro-cell uses an 8-bit register to define their output function.

Table 7-11 shows truth tables for the 3-bit LUT.

Table 7-11. 3-bit LUT Truth Table

7.3.3.4.2 D Flip-Flop/Latch with Reset/Set

When used to implement a sequential logic element, the three input signals from the connection mux go to the data (D), clock (CLK), and reset/set (nRST/nSET) inputs for the flip-flop or latch, with the output going back to the connection mux. This macro-cell has user-configurable initial state, clock polarity, reset/set polarity, and output polarity parameters.

The operation of the D flip-flop/latch will follow the functional descriptions below:

- The clock polarity is configurable and can be set to non-inverted (CLK) or inverted (nCLK).
 - DFF with CLK: CLK is rising edge triggered, then Q = D; otherwise Q will not change.
 - DFF with nCLK: CLK is falling edge triggered, then Q = D; otherwise Q will not change.
 - Latch with CLK: when CLK is Low, then Q = D; otherwise Q remains its previous value (input D has no effect on the output, when CLK is High).
 - Latch with nCLK: when CLK is High, then Q = D; otherwise Q remains its previous value (input D has no effect on the output, when CLK is Low).
- These DFF/Latches have an option for both an active-low and active-high reset/set:
 - nRST: If High, then the DFF/Latch is in normal operation. If Low, then Q is reset to 0.
 - RST: If Low, then the DFF/Latch is in normal operation. If High, then Q is reset to 0.
 - nSET: If High, then the DFF/Latch is in normal operation. If Low, then Q is set to 1.
 - SET: If Low, then the DFF/Latch is in normal operation. If High, then Q is set to 1.
- If reset/set is not desired, users may set the polarity to active-low and connect this input to V_{CC} or a constant High source.
- The output polarity is configurable and can be set to non-inverted (Q) or inverted (nQ).

Table 7-12 and **Table 7-13** show the truth tables for the D flip-flop and D latch with an active-low reset/set, respectively.

Table 7-12. D Flip-Flop with nRST/nSET truth table

nRST	nSET	CLKPOL	CLK	D	Q	nQ

			0	0	Q_0	nQ_0	

7.3.3.4.3 8-Bit Shift Register

When used to implement a shift register, users can configure the initial state, reset/set polarity, output polarity, and register length. The register length can be set to a minimum of 2 and a maximum of 8.

Figure 7-8 shows an example of how the Shift register macro-cell operates.

Figure 7-8. Shift register output timing diagram example (INIT STATE = 00, REG LENGTH = 2, High level RST)

Figure 7-9. Shift register output timing diagram example (INIT STATE = 5Ah, High level RST)

Figure 7-10. Shift register output timing diagram example (INIT STATE = 5Ah, High level SET)

7.3.3.5 4-Bit LUT or D Flip-Flop/Latch with Reset/Set macro-cell

This configurable use logic block can serve as either a 4-bit LUT or as a D flip-flop or latch with a reset or set.

Figure 7-11. 4-bit LUT or DFF/Latch Block Diagram

7.3.3.5.1 4-Bit LUT

When used to implement LUT functions, the 4-bit LUT takes in four input signals from the connection mux and produces a single output, which goes back into the connection mux. This LUT can be configured to any 4-input user defined function, including the following standard digital logic functions (AND, NAND, OR, NOR, XOR, XNOR).

When programmed for a LUT function, this macro-cell uses a 16-bit register to define its output function.

[Table 7-14](#) shows truth tables for the 4-bit LUT.

Table 7-14. 4-bit LUT truth table

7.3.3.5.2 D Flip-Flop/Latch with Reset/Set

When used to implement a sequential logic element, the three input signals from the connection mux go to the data (D), clock (CLK), and reset/set (nRST/nSET) inputs for the flip-flop or latch, with the output going back to the connection mux. This macro-cell has user-configurable initial state, clock polarity, reset/set polarity, output select, and output polarity parameters.

The operation of the D flip-flop/latch will follow the functional descriptions below:

- The clock polarity is configurable and can be set to non-inverted (CLK) or inverted (nCLK).
 - DFF with CLK: CLK is rising edge triggered, then Q = D; otherwise Q will not change.
 - DFF with nCLK: CLK is falling edge triggered, then Q = D; otherwise Q will not change.
 - Latch with CLK: when CLK is Low, then Q = D; otherwise Q remains its previous value (input D has no effect on the output, when CLK is High).
 - Latch with nCLK: when CLK is High, then Q = D; otherwise Q remains its previous value (input D has no effect on the output, when CLK is Low).
- These DFF/Latches have an option for both an active-low and active-high reset/set:
 - nRST: If High, then the DFF/Latch is in normal operation. If Low, then Q is reset to 0.
 - RST: If Low, then the DFF/Latch is in normal operation. If High, then Q is reset to 0.
 - nSET: If High, then the DFF/Latch is in normal operation. If Low, then Q is set to 1.
 - SET: If Low, then the DFF/Latch is in normal operation. If High, then Q is set to 1.
- If reset/set is not desired, users may set the polarity to active-low and connect this input to V_{CC} or a constant High source.
- These DFF/Latches have the option to further isolate the output from the input with the use of a second DFF/Latch and sampling on the falling edge of CLK and enabling the "Dual Stage DFF" option.
- The output polarity is configurable and can be set to non-inverted (Q) or inverted (nQ).

[Table 7-15](#) and [Table 7-16](#) show the truth tables for the D flip-flop and D latch with an active-low reset/set, respectively.

7.3.4 Configurable Logic and Timing blocks

The TPLD2001 has eight configurable logic and timing blocks (macro-cells) that can serve as a combinational or sequential logic function. The configurable logic and timing blocks can serve as a 3-bit LUT, D flip-flop with nRST/nSET, an 8-bit Counter/Delay generator, or a 16-bit Counter/Delay generator. These macro-cells also have the option to combine the previous functions, with a LUT/DFF output connected to the CNT/DLY input or a CNT/DLY output connected to any LUT/DFF input.

ADVANCE INFORMATION

Figure 7-12. LUT/DFF + CNT/DLY Block Diagram

7.3.4.1 3-Bit LUT

When used to implement LUT functions, the 3-bit LUTs each take in three input signals from the connection mux and produce a single output, which goes back into the connection mux. These LUTs can be configured to any 3-input user defined function, including the following standard digital logic functions (AND, NAND, OR, NOR, XOR, XNOR).

When programmed for a LUT function, each macro-cell uses an 8-bit register to define their output function.

Table 7-17 shows truth tables for the 3-bit LUT.

Table 7-17. 3-bit LUT Truth Table

IN2	IN1	IN0	OUT

0	0	1	
0	1	0	
0	1	1	
1	0	0	
1	0	1	
1	1	0	
1	1	1	

7.3.4.2 D Flip-Flop/Latch with Reset/Set

When used to implement a sequential logic element, the three input signals from the connection mux go to the data (D), clock (CLK), and reset/set (nRST/nSET) inputs for the flip-flop or latch, with the output going back to the connection mux. This macro-cell has user-configurable initial state, clock polarity, reset/set polarity, and output polarity parameters.

The operation of the D flip-flop/latch will follow the functional descriptions below:

- The clock polarity is configurable and can be set to non-inverted (CLK) or inverted (nCLK).
 - DFF with CLK: CLK is rising edge triggered, then Q = D; otherwise Q will not change.
 - DFF with nCLK: CLK is falling edge triggered, then Q = D; otherwise Q will not change.
 - Latch with CLK: when CLK is Low, then Q = D; otherwise Q remains its previous value (input D has no effect on the output, when CLK is High).
 - Latch with nCLK: when CLK is High, then Q = D; otherwise Q remains its previous value (input D has no effect on the output, when CLK is Low).
- These DFF/Latches have an option for both an active-low and active-high reset/set:
 - nRST: If High, then the DFF/Latch is in normal operation. If Low, then Q is reset to 0.
 - RST: If Low, then the DFF/Latch is in normal operation. If High, then Q is reset to 0.
 - nSET: If High, then the DFF/Latch is in normal operation. If Low, then Q is set to 1.
 - SET: If Low, then the DFF/Latch is in normal operation. If High, then Q is set to 1.
- If reset/set is not desired, users may set the polarity to active-low and connect this input to V_{CC} or a constant High source.
- The output polarity is configurable and can be set to non-inverted (Q) or inverted (nQ).

Table 7-18 and **Table 7-19** show the truth tables for the D flip-flop and D latch with an active-low reset/set, respectively.

Table 7-18. D Flip-Flop with nRST/nSET truth table

nRST	nSET	CLKPOL	CLK	D	Q	nQ

			1	1	1	0	
			X	X	1	0	
			0	0	Q_0	nQ_0	

7.3.4.3 Counters/Delay Generators (CNT/DLY)

The TPLD2001 has six 8-bit and two 16-bit counters/delay generators, supporting a maximum DATA value of 255 and 65535, respectively. The counter count can be read and the data can be updated in-system using the User Registers. When reading the current count, two consecutive read transactions are required for accurate data read. It is recommended to put the counter in a reset state when updating the counter data registers to prevent glitches during loading of the data. Two clock pulses are required to release the counter from reset after writing new counter data.

For further flexibility, the clock source for each of these macro-cells can be configured as the internal oscillator (OSC0, OSC1, or OSC2), a divided clock derived from an oscillator (OSC0/8, /64, /512, /4096, /32768, /262144, or OSC1/8, /64, /512, or OSC2/4), or an external clock source coming from the connection mux. Note that the counter/delay macro-cell is rising edge triggered, that is the counter will decrement on the rising edge of the CLK input.

Note

For unused counter macro-cells, set the clock selection (CLK_SEL) to External CLK from CMX to reduce excess current draw.

Users may use the counter/delay generator macro-cell in the following modes: delay, one-shot, frequency comparator, counter, edge detector, delayed edge detector.

7.3.4.3.1 Delay Mode

When configured as a Delay generator (DLY), this macro-cell delays the input based on counter DATA and CLK input frequency and postpones rising and/or falling edges. The initial output value of this macro-cell after device startup can also be configured to Bypass Initial, Initial Low, or Initial High. The edge on which to delay is selected by the Edge select parameter and can be configured as:

- **Rising**: only delay on rising edges of IN.
- **Falling**: only delay on falling edges of IN.
- **Both**: delay on both rising and falling edges of IN.

For delay applications, it is recommended to use larger counter data values for less error. If an input pulse width is shorter than the specified delay time, the pulse will be filtered out. This feature can be useful for deglitching.

If the on-chip oscillator is used, a delay error or offset is introduced depending on whether the OSC is set to "forced power on" or "auto power on". An additional 2 clock cycles are included in the delay calculation for clock synchronization.

The delay time is calculated by $\text{DELAY} = (\text{DATA} + (t_{d_err} \text{ or } t_{d_os}) + 3)/f_{\text{CLK}}$.

When the OSC is set to "auto power on" and DLY macro-cells are triggered subsequently before the previous output is present, the OSC will continue to clock and the DLY will begin on the next rising edge. Thus, the subsequent delays can be calculated as if the OSC were set to "forced power on".

Figure 7-13 shows an example of the Delay macro-cell operation set to both edge delay and data = 1.

ADVANCE INFORMATION

Figure 7-13. Delay Output Timing Example (Both Edge Delay and DATA = 1)

Figure 7-14 shows an example timing of Delay macro-cells with respect to the edge selected and data = 3.

Figure 7-14. Delay Output Timing Example (DATA = 3)

7.3.4.3.2 Reset Counter Mode

When configured as a Counter (CNT) and a valid edge appears on the IN input, this macro-cells resets the internal counter to 0 and begins counting down from DATA on the next rising clock edge. Then, the macro-cell outputs a pulse for the duration of one CLK period when the count reaches 0 and wrap around to the value in DATA. The counter will continually operate until another reset is received. The edge on which the Counter is reset is determined by the Edge select parameter and can be configured as:

- **Rising:** only rising edges of IN reset the counter.
- **Falling:** only falling edges of IN reset the counter.
- **Both:** both rising and falling edges of IN reset the counter.
- **High Level Reset:** the counter is reset to 0 whenever IN is High; after reset, the counter output stays Low until the next rising CLK edge, then operates normally.

The counter time is calculated by COUNT = (DATA + 1)/f_{CLK}. After a reset, an additional 2 clock cycles is added for clock synchronization with an option to bypass. Note, bypassing the clock synchronization may result in the counter resetting to an unknown value.

Note

Counters are initialized with DATA = 0 after POR.

[Figure 7-15](#) and [Figure 7-16](#) show examples of Counter output timing diagrams with respect to the Edge select parameter with DATA = 1 and DATA = 3, respectively.

Figure 7-15. Counter Output Timing Example (DATA = 1)

Figure 7-16. Counter Output Timing Example (DATA = 3)

Figure 7-17 shows an example of how the Counter macro-cell operates when the IN signal is shorter than the counter length (shown when edge select parameter is set to "both").

Figure 7-17. Counter Output Timing Example with RST < DATA (DATA = 3)

7.3.4.3.3 One-Shot Mode

When configured as a One-shot, this macro-cell generates a pulse that begins when a valid edge appears on the IN input, which triggers the counter to begin counting down from DATA following two CLK cycles, and the pulse ends once the counter reaches 0 and DATA is subsequently reloaded into the counter and waiting for the next trigger. Triggers received while the counter is decrementing are ignored. The initial output value of this macro-cell after device startup can also be configured to Bypass Initial, Initial Low, or Initial High. The edge on which the One-shot is reset is determined by the Edge select parameter and can be configured as:

- **Rising**: only rising edges of IN reset the one-shot.
- **Falling**: only falling edges of IN reset the one-shot.
- **Both**: both rising and falling edges of IN reset the one-shot.

An additional 2 clock cycles are included in the one-shot pulse width calculation for clock synchronization.

The pulse width of the one-shot is calculated by $\text{ONESHOT} = (\text{DATA} + 3)/f_{\text{CLK}}$.

Figure 7-18 shows an example of how the One-shot macro-cell operates with respect to the Edge select parameter.

Figure 7-18. One-shot output timing example (DATA = 2)

7.3.4.3.4 Frequency Comparator Mode

When configured as a Frequency comparator (FCMP), this macro-cell will indicate whether the input signal is faster or slower than the period specified by DATA. The initial output value of this macro-cell after device startup can also be configured to Bypass Initial, Initial Low, or Initial High. The edge on which the Frequency comparator is reset is determined by the Edge select parameter and can be configured as:

- **Rising:** rising edges of IN trigger and reset the frequency comparator.
- **Falling:** falling edges of IN trigger and reset the frequency comparator.
- **Both:** rising edges of IN triggers the frequency comparator to begin counting and falling edges of IN reset the frequency comparator.

Upon receiving a trigger, an additional 2 clock cycles is used to synchronize IN and the counter with CLK, then the counter begins decrementing from DATA on the following rising edge of CLK.

If the internal counter reaches 0, the FCMP macro-cell will output a Low signal, indicating the input frequency is slower than DATA. Otherwise, if the counter is interrupted with a reset before reaching 0, the FCMP macro-cell will output a High signal, indicating a faster signal on IN.

Figure 7-19 shows an example of how the FCMP macro-cell operates with respect to the Edge select parameter.

Figure 7-19. Frequency comparator output timing example (DATA = 3)

7.3.4.3.5 Edge Detector Mode

When configured as an Edge detector (EDET), this macro-cell will generate a pulse of approximately 20ns width when a valid edge is detected. The edge on which the Edge detector generates a pulse is determined by the Edge select parameter and can be configured as:

- **Rising**: only rising edges of IN generate a pulse.
- **Falling**: only falling edges of IN generate a pulse.
- **Both**: both rising and falling edges of IN generate a pulse.

Figure 7-20 shows an example of how the EDET macro-cell operates with respect to the Edge select parameter.

Figure 7-20. Edge detector output timing example

7.3.4.3.6 Delayed Edge Detector Mode

When configured as a Delayed edge detector (Delayed EDET), this macro-cell will delay the input by the value in DATA and then generate a pulse of approximately 20ns width when the selected edge is detected on the delayed input. The initial output value of this macro-cell after device startup can also be configured to Bypass Initial, Initial Low, or Initial High. The edge on which to delay and then output an edge detect pulse is selected by the Edge select parameter and can be configured as:

- **Rising:** only delay on rising edges of IN.
- **Falling:** only delay on falling edges of IN.
- **Both:** delay on both rising and falling edges of IN.

Upon receiving a trigger, an additional 2 clock cycles is used to synchronize IN and the counter with CLK, then the counter begins decrementing from DATA on the following rising edge of CLK. If the counter is allowed to reach 0 and wrap around back to DATA, the Delayed EDET macro-cell will output a pulse. Otherwise, if the counter is interrupted with a reset before reaching 0, the Delayed EDET macro-cell "filter out" the previous edge.

Figure 7-21 shows an example of how the Delayed EDET macro-cell operates with respect to the Edge select parameter.

Figure 7-21. Delayed edge detector output timing example (DATA = 3)

7.3.4.4 LUT/DFF + CNT modes

In addition to the discrete LUT, DFF/latch, or counters described previously, the configurable logic and timing blocks can be configured in two other modes:

- Mode 1: LUT/DFF into counter. The three inputs from the connection mux go into the LUT/DFF/LAT and the output of the first stage feed into the input of the counter. The output of the counter goes back into the connection mux.
- Mode 2: Counter into LUT/DFF. One input from the connection mux goes to the counter input and the output feeds into any one input of the LUT or the DFF/LAT. The output of the second stage goes back into the connection mux.

This feature enables more LUTs, DFFs/latches, and counters to be used in a design. However, within a single block, only the LUT or only the DFF/latch may be used. Further, in these modes, the external clock source from the connection mux for the counter is disabled, thus, only a frequency derived from the internal oscillator can be used.

7.3.5 Programmable Deglitch Filter or Edge Detector

The TPLD2001 has two macro-cells that can be configured as a Programmable filter (PFLT) or Edge detector (EDET). The PFLT macro-cell can be used to generate a delay (t_{pflt_d}) characterized by t_{pflt_pw} and t_{pflt_pd} . t_{pflt_pw} can be set to 125ns, 250ns, 375ns, or 500ns and t_{pflt_pd} is a fixed value at ~15ns. Furthermore, the output of the macro-cell can be configured to one of four options: rising edge detection, falling edge detection, both edge detection, or both edge delay. Lastly, the filter operates as a short low-pass filter and its output can be set as non-inverted or inverted.

Figure 7-22. Programmable Filter/Edge Detector Block Diagram

Note

The input signal must be longer than the t_{pflt_d} , otherwise it will be filtered out.

Figure 7-23. Delayed edge detector output timing diagram

7.3.6 Deglitch Filter or Edge Detector

The TPLD2001 has one macro-cell that can be configured as a Deglitch filter or an Edge detector.

Figure 7-24. Deglitch Filter or Edge Detector Block Diagram

The Deglitch filter operates as short low-pass filter and the filter output can be set as non-inverted or inverted.

As an Edge detector, this macro-cell can be configured to output a short pulse that is triggered on the rising edge, the falling edge, both edges, or act as a filter and delay both edges. The edge detector output can be set as non-inverted or inverted.

7.3.7 State Machine (SM)

The TPLD2001 features a state machine macro-cell that can be operated synchronously or asynchronously with 24 state transition inputs, 1 clock input, 1 state machine reset input, and 8 outputs. This macro-cell can be configured to create a 2- to 8-state state machine, where the states, state transition conditions, state transition inputs, and state outputs are user-defined. Each state has a maximum of 3 transition conditions that can trigger a transition into that particular state, limited by the state transition inputs that are hardwired in the connection mux.

Figure 7-25. State Machine Block Diagram

7.3.7.1 State Machine Inputs

The state machine macro-cell has 26 inputs from the connection mux: 24 state transition inputs, 1 clock input, and 1 reset input.

Each of the 24 state transition inputs are active-high inputs, meaning a high-level input would trigger a state transition given the timing considerations are met. Further, these 24 inputs are grouped such that each set of 3 inputs drives a transition into a particular state. For example, there are 3 inputs that drives a transition from any state into State 2. Thus, this limits the maximum number of transitions into a particular state to 3.

When operating the state machine in synchronous mode and a state transition condition is met, the state transition will occur on the next rising edge of the clock input. In asynchronous mode, when a state transition condition is met, the state transition occurs asynchronously and the clock input is unavailable/ignored.

There is also an active-low, asynchronous reset input which, when asserted, puts the state machine into a reset state and, when released, will place the state machine in the user-selected initial state.

7.3.7.2 State Machine Outputs

The state machine macro-cell has 8 outputs into the connection mux. With an 8-byte RAM, users are able to set the behavior of the 8 outputs for each defined state, which could be seen as 8 parallel outputs that can be configured depending on the current state. Each of the 8 outputs are connection mux inputs that could be elsewhere in the design, such as an input into a LUT, D flip-flop, counter, or out to a GPO pin.

The state machine outputs can be updated in-system using the User Registers. For glitch-free operation, it is recommended to put the state machine in a reset while the state machine output bits are being modified.

7.3.7.3 Configuring the State Machine

The following can be configured for an operating state machine: states, initial state, state transitions, mode, clock polarity.

- **States:** Up to 8 states can be used.
- **Initial state:** One of the states used can be selected as the initial state in which the state machine macro-cell will reset to following an asynchronous reset.
- **State transition(s):** Users can set the transition from one state into another to enable a state transition condition input, with a maximum of 3 transitions into a particular state. The state transition conditions are inputs from the connection mux and can be configured to come from any GPI or other macro-cell outputs.
- **Mode:** The state machine can be selected to operate in synchronous mode, in which state transition conditions are synchronously latched in with respect to the clock input, or asynchronous mode.
- **Clock polarity:** In synchronous mode, this setting will determine whether the state machine is rising edge triggered, that is state transition inputs and state transitions are latched in on the rising edge of the clock, or falling edge triggered.

The serial communication interface, if enabled, can be used to read the current state of an active state machine and reconfigure the state outputs. Any changes made to the state machine configuration through the serial communication interface will only be reflected after the next state transition or a reset event. Thus, to guarantee the desired behavior, it is best practice to keep the state machine in reset while reconfiguring the macro-cell.

7.3.7.4 State Machine Timing Considerations

When the state machine macro-cell is in operation, especially when operating asynchronously, the state transition inputs timing requirement, delays in the I/O, other macro-cells used in the state transition input path, and the connection mux need to be taken into consideration to ensure inputs are properly processed and state transitions are deterministic.

In synchronous mode, state transition trigger input needs to be asserted for at least 2 clock cycles, otherwise the input will be ignored. In asynchronous mode, the state transition trigger input needs to be asserted for at least the state transition pulse width, t_{st_pw} . If a state transition condition is met, the transition will occur after the state transition delay, t_{st_dly} .

Figure 7-26. State transitions

Figure 7-27. State transition trigger requirements timing example

When two or more state transition input triggers exist within the state transition pulse width, t_{st_pw} , the next state is indeterminate. To avoid such cases, careful consideration must be taken in the timing of the state transition inputs.

Figure 7-28. State transitions with competing triggers

Figure 7-29. State transition with competing triggers considerations timing example

Figure 7-30. State transition considerations for deterministic transition timing example

For sequential state transitions or closed loop state transitions, where state transition input triggers are asserted that prompt the state machine to go into a next state, transitions into consecutive states will occur after the state transition delay, t_{st_dly} . Thus, the state machine will remain in the current state for at least t_{st_dly} .

Figure 7-31. Sequential state transition

Figure 7-32. Sequential state transition timing example

The closed loop state transition example shown only considers two states; however, the closed loop can be made with any number of states from two to the maximum of eight.

Figure 7-33. Closed loop state transition

Figure 7-34. Closed loop state transition timing example

7.3.8 8-Bit Counters/Delay Generators/Finite State Machines

The TPLD2001 has four 8-bit counters that can operate as a finite state machine (FSM) while in Reset counter mode in addition to the modes outlined in [Section 7.3.4.3](#). These 8-bit counter macro-cells have 4 inputs from the connection mux: counter input, FSM up/down, FSM keep, and external clock input; and 1 output into the connection mux: counter out. There is also an 8-bit parallel output of the current count value from this macro-cell that routes directly into the pulse-width modulation (PWM) generator macro-cells.

Figure 7-35. CNT/DLY/FSM block diagram

The following can be configured for an operating FSM: counter reset data and clock.

- Counter reset data: The value which the counter will load when a reset condition is met and can be set to any value between 1 and 255. The counter data can be updated in-system using the User Registers. It is recommended to put the counter in a reset state when updating the counter data registers to ensure glitch-free loading of the data.
- Edge select, the edge in which to asynchronously reset the counter to the initial counter data: Both, Rise, Fall, or High-level reset.
- Clock input: OSC0, a divided clock derived from OSC0 (/8, /64, /512, /4096, /32768, /262144), OSC1, a divided clock derived from OSC1 (/8, /64, /512), OSC2, a divided clock derived from OSC2 (/4), or an external clock.

Note

For unused counter macro-cells, set the clock selection (CLK_SEL) to External CLK from CMX to reduce excess current draw.

The FSM UP input determines the direction of the counter/FSM, whether the count will decrement or increment with respect to the rising edge of the clock input. While **FSM UP** = Low, the counter will decrement (count downward) and reset to the initial counter data once 0 is reached; and while **FSM UP** = High, the counter will increment (count upward) and reset to the initial counter data once 255 is reached.

The **FSM KEEP** input will pause, or latch, the current count and ignore any **FSM UP** or **clock** input. The **count reset** input will still reset the counter, but will neither decrement nor increment. While **FSM KEEP** = Low, the counter will count as configured; and while **FSM KEEP** = High, the counter will pause.

After a trigger of **UP** or **KEEP**, an additional 2 clock cycles is added for clock synchronization with an option to bypass. Note, bypassing the clock synchronization may result in the counter resetting to an unknown value.

ADVANCE INFORMATION

Figure 7-36. CNT/FSM timing example (DATA = 3)

Figure 7-37. CNT/FSM with UP/KEEP timing example (DATA = 3)

7.3.9 PWM Generators

The TPLD2001 has four pulse-width modulation (PWM) generators that outputs a square wave with a duty cycle proportional to the counter value from the selected FSM. These PWM generator macro-cells have 1 input from the connection mux to control the macro-cell power up; 1 input directly from FSM blocks; and 2 outputs into the connection mux.

Figure 7-38. PWM Generator Block Diagram

The following can be configured for an operating PWM generator: input source, deadband time, output polarity, clock.

- Data input source (IN): Any of the four FSMs can be selected to provide the counter value.
- Deadband time (t_{db}): 0 CLKs (no deadband), 1 CLK, 2 CLKs, or 5 CLKs.
- Output polarity: the polarity of each output (OUT+ and OUT-) can be configured to non-inverted or inverted.
- Clock: OSC0, a divided clock derived from OSC0 (/8, /64, /512, /4096, /32768, /262144), OSC1, a divided clock derived from OSC1 (/8, /64, /512), OSC2, or a divided clock derived from OSC2 (/4).

The PWM generator macro-cell reads the count value of the selected FSM once every 256 clock cycles. Thus, the PWM generator output frequency is determined by $f_{CLK}/256$. Further, the duty cycle of the PWM signal calculated by: Duty cycle (%) = $(IN / 256) * 100$, with a minimum duty cycle of 0% (or 0/256) and a maximum of 99.61% (or 255/256).

Note, upon startup of the PWM generator, the macro-cell requires 2 clock cycles for clock synchronization. If the selected deadband time is greater than the FSM counter data input, a constant low will appear on the non-inverted OUT- output. Additionally, the PWM generator macro-cell can be powered down by sending a LOW signal to the PWM PWR UP input to prevent outputting in an idle state.

Figure 7-39. PWM Generator Timing Example

7.3.10 Watchdog Timer

The watchdog timer (WDT) macro-cell monitors the input into the macro-cell for any edge (rising or falling) in the time frame defined by the t_{WD} time period. The WDT macro-cell has 2 inputs from the connection mux: 1 active-high enable and 1 watchdog input. There is also 1 clock input directly from the internal oscillators.

Figure 7-40. Watchdog Timer Block Diagram

The following can be configured for an operating WDT: the timeout period (t_{WD}), the output assert time (t_{WDO}), the clock source, an additional clock divider option, behavior of WDT while disabled.

- Timeout period (t_{WD}): The WDT operates on an 8-bit counter and supports count data values of 5 to 255.
- Output assert time (t_{WDO}): A separate 8-bit counter controls the output assertion time period, supporting count data values of 1 to 255.
- Clock source: OSC0, a divided clock derived from OSC0 (/8, /64, /512, /4096, /32768, /262144), OSC1, a divided clock derived from OSC1 (/8, /64, /512), OSC2, or a divided clock derived from OSC2 (/4).
- Additional clock division: An additional clock divide by 100 can be toggled to further extend the timeout period.
- Behavior while disabled: Users can set the counter to reset to the specified count data when the WDT is disabled or to pause the counter and resume once the WDT is re-enabled.

When a timeout condition is reached, the WDT macro-cell outputs a Low pulse for the specified amount of time.

Note

For unused watchdog timer macro-cell, set the clock selection (CLK_SEL) to External CLK from CMX to reduce excess current draw.

Figure 7-41. Watchdog timer output timing example (reset count when disabled)

Figure 7-42. Watchdog timer output timing example (pause count when disabled)

7.3.11 Analog Comparators

The TPLD2001 has four discrete analog comparators (ACMP) and one multi-channel sampling comparator (McACMP). The ACMP and McACMP compares two voltages (IN+ and IN-) and outputs a digital signal (OUT) indicating which is larger, a High signal for IN+ and a Low for IN-.

Figure 7-43. Analog Comparators Block Diagram

7.3.11.1 Discrete Analog Comparator (ACMP)

In order for the ACMP macro-cell to be used in a TPLD design, the power up (PWR UP) port needs to be connected to a logic High signal. By connecting to signals coming from the connection mux, it is possible to have the ACMP always on, always off, or switched on dynamically based on a digital signal coming from the connection mux.

- PWR UP = 1 => ACMP is powered up.
- PWR UP = 0 => ACMP is powered down.

When powered down, the output of the ACMP is a static logic Low. Upon power up, the output will remain Low, and then become valid 110 µs (max) after the PWR UP signal goes high, during which time, ensure OSC1 is not powered down.

The ACMP macro-cell has a positive input signal that can be provided by a variety of external sources with a selectable gain stage before going into the analog comparator. The negative input signal can either come from the internal VREF or an external source, which is shared between all comparator channels.

Table 7-20. ACMP Input Sources

Parameters	Source
IN+ source	ACMP IN0
	ACMP IN1
	ACMP IN2
	ACMP IN3

IN+ gain: The McACMP positive input can be provided by a variety of external sources, and can also have a selectable gain stage (1X, 0.5X, 0.33X, 0.25X) before connecting to the analog comparator.

IN- voltage range: 32 mV to 2.016 V through the internal VREF or up to 2.016 V external source.

The VREF selection per discrete analog comparator may be updated in-system using the User Registers. For glitch-free measurements, it is recommended to disable/power down all analog comparators when changing the VREF. If the analog comparator is not disabled while the VREF selection is being updated, it may take up to 10µs for valid data to be output from the analog comparators.

Hysteresis: If the internal VREF is used, corresponding ACMP channels have four selectable hysteresis options 0 mV, 32 mV, 64 mV and 192 mV.

- **0 mV:** will disable the input signal hysteresis.
- **64 mV:** is a +32 mV and -32 mV hysteresis. For VREF = 1.024 V, the trigger points will be 1.056 V and 0.992 V.
- **128 mV:** is a +64 mV and -64 mV hysteresis. For VREF = 1.024 V, the trigger points will be 1.088 V and 0.960 V.
- **192 mV:** is a +96 mV and -96 mV hysteresis. For VREF = 1.024 V, the trigger points will be 1.120 V and 0.928 V.

If hysteresis is desired, the internal VREF must be used. Further, hysteresis values that would otherwise extend beyond the range of the VREF will be limited to the minimum and maximum values available in the device. For example, if IN- = 1.984 V and VHYS = ±64 mV, the lower trigger point will be 1.920 V and the upper trigger point will be 2.016 V.

Low bandwidth: The ACMP cell has a selection for the bandwidth of the input signal, which can be used to save power and reduce noise impact when lower bandwidth signals are being compared.

7.3.11.2 Multi-channel Analog Comparator (McACMP)

In order for the McACMP macro-cell to be used in a TPLD design, the power up (PUP) port needs to be connected to a logic High signal. By connecting to signals coming from the connection mux, it is possible to have the McACMP always on, always off, or switched on dynamically based on a digital signal coming from the connection mux.

- PUP = 1 => McACMP is powered up.
- PUP = 0 => McACMP is powered down.

Upon power up, the output will remain static and then become valid t_{start} after the PUP signal goes high, during which time, ensure OSC1 is not powered down.

The McACMP macro-cell has a positive input signal that can be provided by a variety of external sources with a selectable gain stage before going into the analog comparator. The negative input signal can either come from the internal VREF or an external source, which is shared between all comparator channels. Each channel has the option to select up to four negative input points to compare against.

Table 7-21. McACMP Input Sources

Parameters	Primary source	Secondary source
IN+ source	McACMP IN0	
	McACMP IN1	
	McACMP IN2	V _{CC}
	McACMP IN3	Temp. sensor

IN+ gain: The McACMP positive input can be provided by a variety of external sources, and can also have a selectable gain stage (1X, 0.5X, 0.33X, 0.25X) before connecting to the analog comparator.

IN- voltage range: 32 mV to 2.016 V through the internal VREF or up to 2.016 V external source.

The VREF selection per channel of the multi-channel sampling analog comparator may be updated in-system using the User Registers. For glitch-free measurements, it is recommended to disable/power down all analog comparators when changing the VREF. If the analog comparator is not disabled while the VREF selection is being updated, it may take up to 10µs for valid data to be output from the analog comparators.

Hysteresis: If the internal VREF is used, corresponding McACMP channels have four selectable hysteresis options 0 mV, 32 mV, 64 mV and 192 mV.

- **0 mV:** will disable the input signal hysteresis.
- **64 mV:** is a +32 mV and -32 mV hysteresis. For VREF = 1.024 V, the trigger points will be 1.056 V and 0.992 V.
- **128 mV:** is a +64 mV and -64 mV hysteresis. For VREF = 1.024 V, the trigger points will be 1.088 V and 0.960 V.
- **192 mV:** is a +96 mV and -96 mV hysteresis. For VREF = 1.024 V, the trigger points will be 1.120 V and 0.928 V.

If hysteresis is desired, the internal VREF must be used. Further, hysteresis values that would otherwise extend beyond the range of the VREF will be limited to the minimum and maximum values available in the device. For example, if IN- = 1.984 V and VHYS = ±64 mV, the lower trigger point will be 1.920 V and the upper trigger point will be 2.016 V.

When only one channel and one VREF is selected, the McACMP will disable the sampling engine and operate as a discrete analog comparator.

In multi-channel sampling mode, the TPLD2001 can be configured to sample up to 4 channels, each with its own selectable gain, voltage reference, and hysteresis (if the internal VREF is used). The sampling clock can be selected from the output of OSC0 or OSC1 with a given pre-divider and an additional divider at the McACMP. Other configurations that can be set are the output synchronicity, the trigger to begin a sample sequence, a sequence restart and output latch reset/clear input, and the option to select up to 2 VREFs per channel.

When sampling in multi-channel mode, the McACMP will sample the set channels in sequential order (channel 0 through channel n) and the edge of the clock on which samples are captured can be selected.

Clock: The McACMP sampling clock can be selected to be OSC1 / 20, OSC1 / 40, OSC0, or OSC0 / 2.

Table 7-22. McACMP Clock Options

Base Frequency	Pre-dividers	Dividers
2kHz	1	1
	2	2
	4	
	8	
2MHz	1	20
	2	40
	4	
	8	

Enable trigger:

- **Edge sensitive PUP mode:** The McACMP will begin one sampling sequence when a rising edge is detected at the PUP input and then enter an idle state.
- **Level sensitive PUP mode:** The McACMP will begin the sampling sequence when a high signal is detected at the PUP input and continuously sample as long as PUP is high, and once PUP goes low, the McACMP will finish the sampling sequence before entering an idle state.

Output synchronicity:

- **Simultaneous:** Sampled outputs will be latched and then appear at their respective channel output after the last channel is sampled.
- **Staggered:** Sampled outputs will appear at their respective channel output as they are sampled.

Sampling edge select:

- **Negative edge:** samples are captured on the negative or falling edge of the clock.
- **Positive edge:** samples are captured on the positive or rising edge of the clock.

Sequence restart/output latch reset: while the McACMP is running, a restart/reset signal can be asserted to restart the sampling sequence from channel 0. Channels can also independently be selected to have the output latch data cleared when this signal is asserted.

There is also a data ready output that will assert a high signal for one clock of the base clock frequency once all channels configured have been sampled. For example, if the 1kHz (2kHz/2) sampling clock is selected, the data ready pulse width will be 500µs.

Figure 7-44 shows an example of a McACMP configured to sample channel 0 and channel 1 with 2 VREFs each and only channel 0 with the output latch reset enabled.

Figure 7-44. Multi-channel Sampling Comparator Timing Example

7.3.12 Voltage Reference (VREF)

The TPLD2001 has a voltage reference macro-cell to provide references to the analog comparators. This macro-cell provides a user selection of fixed voltage references from 32 mV to 2.016 V in 32 mV increments or an externally supplied voltage reference from the External VREF AIO can be provided. The External VREF option is shared between all comparators and all channels of the McACMP.

When operating on a V_{CC} less than 2.3 V, the maximum VREF option is reduced to $V_{CC} - 0.3$ V; thus, the maximum VREF when operating at 1.8 V supply is 1.504 V.

The VREF selection per discrete analog comparator or per channel of the multi-channel sampling analog comparator can be updated in-system using the User Registers. For glitch-free measurements, it is recommended to disable/power down all analog comparators when changing the VREF. If the analog comparator is not disabled while the VREF selection is being updated, it may take up to 10 μ s for valid data to be output from the analog comparators.

Table 7-23. VREF Selection Table

Bit Enumeration	VREF output
000000	32 mV
000001	64 mV
000010	96 mV
000011	128 mV
000100	160 mV
000101	192 mV
000110	224 mV
000111	256 mV
001000	288 mV
001001	320 mV
001010	352 mV
001011	384 mV
001100	416 mV
001101	448 mV
001110	480 mV
001111	512 mV
010000	544 mV

7.3.13 Analog Temperature Sensor (TS)

The TPLD2001 has an Analog temperature sensor (TS) macro-cell that operates from -40°C to +125°C. The linear transfer function has a slope of -0.00446 V/°C (typ.) and an output voltage of 1.0536 V (typ.) at 0°C. The TS macro-cell has a ±5°C accuracy across the specified temperature range.

Figure 7-45. Analog temperature sensor block diagram

The formula to convert from temperature (T, in celsius) to sensor output (V_{out} , in volts) is: $V_{out} = -0.00446 * T + 1.0536$.

7.3.14 Analog Multiplexer (AMUX)

The TPLD2001 has two Analog multiplexer (AMUX) macro-cells that operate as break-before-make, single-pole double-throw (SPDT) analog switches. This AMUX can handle both analog and digital signals and permits signals with amplitudes of up to V_{CC} (peak) to be transmitted in either direction.

Figure 7-46. Analog multiplexer block diagram

Either the A channel or the B channel is activated depending upon the control input from the connection mux. If the control input is Low, A channel is selected. If the control input is High, B channel is selected.

Table 7-25. AMUX Function Table

Control input (CMX_OUT)	On channel
Low	AMUX Y = AMUX A
High	AMUX Y = AMUX B

7.3.15 Oscillators

The TPLD2001 has three internal oscillators, OSC0 is fixed to 2kHz, OSC1 is fixed to 2MHz, and OSC2 is fixed to 25MHz. The user can also bypass in the internal oscillators and the operating frequency can come from an external clock input coming from an IO.

7.3.15.1 2kHz Fixed Frequency Oscillator

The TPLD2001 has one internal oscillator operating at 2kHz. The user can use the oscillator at this operating frequency for the OSC macro-cell, or the internal oscillator could be bypassed and the operating frequency can come from an external clock.

Figure 7-47. Fixed frequency oscillator block diagram

Following the operating clock input, there are two divider stages that allow users the flexibility of various clock frequencies for use throughout the device.

The first stage divider allows the selection of up to four options from the operating oscillator frequency as listed in [Table 7-27](#). The output of the first divider stage is routed directly to the counter/delay generator macro-cell CLK inputs, where a separate second divider stage is available.

The output of the first divider stage is also routed into a second divider stage within the oscillator macro-cell. The oscillator macro-cell has a separate second stage divider, with an output (OUT0) into the connection mux, see [Table 7-28](#).

7.3.15.2 2MHz Fixed Frequency Oscillator

The TPLD2001 has one internal oscillator operating at 2MHz. The user can use the oscillator at this operating frequency for the OSC macro-cell, or the internal oscillator could be bypassed and the operating frequency can come from an external clock.

**Figure 7-48. Fixed frequency oscillator block diagram**

Following the operating clock input, there are two divider stages that allow users the flexibility of various clock frequencies for use throughout the device.

The first stage divider allows the selection of up to four options from the operating oscillator frequency as listed in [Table 7-30](#). The output of the first divider stage is routed directly to the counter/delay generator macro-cell CLK inputs, where a separate second stage divider is available.

The output of the first divider stage is also routed into a second divider stage within the oscillator macro-cell. The oscillator macro-cell has a separate second stage divider, with an output (OUT0) into the connection mux, see [Table 7-31](#).

7.3.15.4 Oscillator Power Modes

When using any of the device's internal oscillator, there are three power modes available for each oscillator:

- **Auto power on (CTRL_SRC = 0 and PWR_MODE = 0):** the internal oscillator will be triggered when any macro-cell that requires the oscillator is running and then power off once the task is complete.
- **Force power on (CTRL_SRC = 0 and PWR_MODE = 1):** the internal oscillator will continuously run as long as the device is powered on.
- **External power on/off (CTRL_SRC = 1, CTRL_SEL = 0, and PWR_MODE = 1):** a High input into the PDWN input will power down the oscillator and a Low will power on the oscillator.

These power modes are only applicable when the internal oscillator is selected and is bypassed when an external clock (SRC_SEL = 1) is used.

7.3.16 Serial Communications

The TPLD2001 has a serial communications macro-cell for in-system updates to certain configuration registers. This macro-cell can configure the TPLD2001 as an I²C or SPI peripheral device.

7.3.16.1 I²C Mode

Figure 7-50. I²C Serial Communications GPIO Allocation

When configured to I²C, the following IOs are used by the macro-cell:

- IO6: SCL
- IO7: SDA
- IO5: HW defined ADDR 3, A3 (optional)
- IO4: HW defined ADDR 4, A4 (optional)
- IO3: HW defined ADDR 5, A5 (optional)
- IO2: HW defined ADDR 6, A6 (optional)

The TPLD2001 supports:

- Peripheral/Target mode only
- Standard mode, Fast mode, and Fast mode plus
- Configurable 4-bit hardware address by IO or by OTP memory

The bidirectional I²C bus consists of the serial clock (SCL) and serial data (SDA) lines. Both lines must be connected to a positive supply through a pull-up resistor when connected to the output stages of a device. Data transfer may be initiated only when the bus is not busy.

The target device address of the TPLD is derived from the OTP and the most significant byte have an option to come from IOs, which the TPLD will continuously sample while powered on. There is also an option to enable IO latching to sample the IO only at power up of the TPLD device, which will allow use of the respective GPIO as a digital input within a circuit design.

Figure 7-51. I²C Read/Write Timing Diagram

Figure 7-52. TPLD I²C Frame and Formatting

I²C communication with this device is initiated by a controller sending a START condition, a high-to-low transition on the SDA input/output, while the SCL input is high. After the START condition, the device hardware address byte is sent, most significant bit (MSB) first, including the data direction bit (R/W).

After receiving the valid address byte, this device responds with an acknowledge (ACK), a low on the SDA input/output during the high of the ACK-related clock pulse. The address input of the responder device must not be changed between the START and the STOP conditions.

On the I²C bus, only one data bit is transferred during each clock pulse. The data on the SDA line must remain stable during the high pulse of the clock period, as changes in the data line at this time are interpreted as control commands (START or STOP).

A STOP condition, a low-to-high transition on the SDA input/output while the SCL input is high, is sent by the controller.

Any number of data bytes can be transferred from the transmitter to receiver between the START and the STOP conditions. Each byte of eight bits is followed by one ACK bit. The transmitter must release the SDA line before the receiver can send an ACK bit. The device that acknowledges must pull down the SDA line during the ACK clock pulse, so that the SDA line is stable low during the high pulse of the ACK-related clock period. When a responder receiver is addressed, it must generate an ACK after each byte is received. Similarly, the controller must generate a NACK after each byte that it receives from the responder transmitter. Setup and hold times must be met for proper operation.

A controller receiver signals an end of data to the responder transmitter by not generating an acknowledge (NACK) after the last byte has been clocked out of the responder. This is done by the controller receiver by holding the SDA line high. In this event, the transmitter must release the data line to enable the controller to generate a STOP condition.

When writing or reading from the TPLD2001, there is an option to enable automatic address incrementing by writing a logic 0 to bit 0 of address 0x0FD. This can be disabled by writing a logic 1. Note, for I²C, the address auto-increment only works within a specific extended, or page, address. Thus, if burst read or write is used, keep in mind 0xFF will roll over to 0x000.

Figure 7-53. TPLD I²C Write Command Formatting

To transmit data or write to the TPLD2001, the bus controller must send the device hardware address and set the least significant bit (LSB) to a logic 0. The next two bytes set the register address and then the write data follows. There is no limitation on the number of data bytes sent in one write frame.

Figure 7-54. TPLD I²C Read Command Formatting

To read from the TPLD2001, the bus controller first must send the TPLD2001 hardware address with the LSB set to a logic 1. The byte that follows contains the data in the address previously written to, or the next address if address auto-increment is enabled.

Figure 7-55. TPLD I²C Software Reset Command

The Software Reset call is a command sent from the controller on the I²C bus that instructs all devices that support the command to be reset to the power-up default state. In order for it to function as expected, the I²C bus must be functional and no devices can be hanging the bus.

The software Reset call is defined as the following steps:

1. A START condition is sent by the I²C bus controller.
2. The address used is the reserved General Call I²C bus address '0000 000' with the R/W bit set to 0. The byte sent is 0x00.
3. Any devices supporting the General Call functionality will ACK. If the R/W bit is set to 1 (read), the device will NACK.
4. Once the General Call address is acknowledged, the controller sends only 1 byte of data equal to 0x06. If the data byte is any other value, the device will not acknowledge nor reset. If more than 1 byte is sent, no more bytes will be acknowledged and the device will ignore the I²C message considering it invalid.
5. After the 1 byte of data (0x06) is sent, the controller sends a STOP condition to end the Software Reset call sequence. A repeated START condition will be ignored by the device and no reset would be performed.

Once the above steps are completed successfully, the device will perform a reset, clearing all register values back to power-on defaults.

7.3.16.2 SPI Mode

Figure 7-56. SPI Serial Communications GPIO Allocation

When configured to SPI, the following IOs are used by the macro-cell:

- IO5: nCS
- IO6: SCLK
- IO7: SDI
- IO8: SDO

The TPLD2001 supports:

- Peripheral/Target mode only
- SPI mode 0, that is, SCLK is idle Low and SDI/SDO is valid on the rising edge of SCLK
- Up to 4MHz SCLK
- 8-bit data frame size

The SPI communication uses a standard SPI interface. Physically, the digital interface pins are nCS (Chip select not), SDI (Serial Data In), SDO (Serial Data Out), and SCLK (SPI Clock).

Figure 7-57. SPI Write Timing Diagram

Figure 7-58. SPI Read Timing Diagram

The SPI module in TPLD2001 supports mode 0, thus input data on the SDI line is sampled on the rising edge of SCLK. The SPI output data on the SDO line is changed on the falling edge of SCLK.

Figure 7-59. TPLD SPI Frame and Formatting

Each SPI transaction consists of a 1-bit command, a 7-bit extended address, an 8-bit target register address, and an 8-bit data field. The data shifted out on the SDO line contains the data that is stored in the set address with the READ command. Data bytes shifted out during a WRITE command is content of the registers prior to the new data being written.

When writing or reading from the TPLD2001, there is an option to enable automatic address incrementing by writing a logic 0 to bit 0 of address 0x0FD. This can be disabled by writing a logic 1.

7.3.16.3 Virtual I/Os

Within the TPLD, this macro-cell has 8 inputs and 8 outputs to allow for reading of up to 8 digital macro-cell outputs and provide up to 8 virtual inputs to be used within the device.

Figure 7-60. Serial Communications Block Diagram

The outputs of this macro-cell act as virtual inputs into the device. The routing of the signal into the Connection Mux is shared with the physical digital input pins, so if a virtual input is used, the digital input pin resource is no longer available and the Connection Mux input is sourced from the Virtual Input register. [Table 7-35](#) shows the shared resource between the digital input pin and the virtual input.

Table 7-35. Digital IO and Virtual In Shared Resources

Virtual input	VIR_IN0	VIR_IN1	VIR_IN2	VIR_IN3	VIR_IN4	VIR_IN5	VIR_IN6	VIR_IN7
Digital input pin	IO1	IO2	IO3	IO4	IO5	IO6	IO7	IO8

Using the virtual inputs and virtual outputs, the TPLD can be configured for 8-bit serial-to-parallel GPIO expansion or parallel-to-serial buffering.

Figure 7-61. Serial Communications for Serial-to-Parallel I/O Expander Block Diagram

Figure 7-62. Serial Communications for Serial-to-Parallel I/O Expander Timing Example

Figure 7-63. Serial Communications for Parallel-to-Serial Block Diagram

Figure 7-64. Serial Communications for Parallel-to-Serial Timing Example

7.4 Device Functional Modes

7.4.1 Power-On Reset

The TPLD2001 has a power-on reset (POR) macro-cell to ensure correct device initialization and operation of all macro-cells in the device. The purpose of the POR circuit is to have consistent behavior and predictable results when the V_{CC} power is first ramping to the device, and also while the V_{CC} is falling during power-down. To accomplish this goal, the POR drives a defined sequence of internal events that trigger changes to the states of different macro-cells inside the device, and finally to the state of the I/O pins.

The power-on Reset (POR) macro-cell will produce a logic HIGH signal as an output when the device power supply (V_{CC}) rises to approximately V_{PORR} and device completely starts up. All outputs are in high impedance state and chip starts loading data from OTP. The reset signal is released for internal macro-cells and all the registers are initialized to their default states. [Figure 7-65](#) shows POR system generates a sequence of signals that enable certain macro-cells.

Figure 7-65. POR Sequence

As can be seen from [Figure 7-65](#) after the V_{CC} has start ramping up and crosses the V_{PORR} threshold,

- First, the on-chip OTP memory is reset.
- Next the chip (TPLD2001) reads the data from OTP, and transfers this information to RAM (registers) that serve to configure each macro-cell, and the connection mux which routes signals between macro-cells.
- The third stage causes the reset of the input pins (GPIOs that are configured as Inputs), and then to enable them.
- After that, the LUTs are reset and become active. After LUTs the Delay cells, RC OSC, DFFs, Latches and Pipe Delay are initialized.
- After all macro-cells are initialized internal POR signal (POR macro-cell output) goes from LOW to HIGH.
- The last portion of the device to be initialized are the output PINs, which transition from high impedance to active at this point.

Delay blocks will pass their inputs through during the startup sequence without delaying the signal per the configuration, so a LUT added in front of the input of a DLY that ANDs the DLY input with POR will guarantee the input signal will not appear until the chip has fully powered up and will enforce delays.

Initialization: All internal macro-cells by default have initial low level. Starting from when $V_{CC} > V_{PORR}$, macro-cells in the TPLD2001 are powered on and forced into a reset state. All outputs are in Hi-Z and the chip starts loading data from OTP. Then the reset signal is released for internal macro-cells and they begin to initialize according to the following sequence:

- Input pins, analog comparators, pull up/pull down resistors
- LUTs
- DFFs, Delays/Counters, pipe delay
- POR output to matrix
- Output pin corresponds to the internal logic

The POR signal going high indicates the mentioned power-up sequence is complete.

7.4.2 Power Supply Control Modes

The TPLD2001 has the option to control the power mode of the Bandgap Voltage and the Prebias Voltage. It is recommended to keep these bits to 00 (auto power on/off); however, if analog macro-cells (i.e., oscillators, analog comparators) are not used, these settings can be used to power off the Bandgap and Prebias Voltages to further reduce the power consumption of the device.

Table 7-36. Power Control Modes

Control code	Bit description
00	Auto
01	Exclude DFFs & counters that use an external clock
10	Always ON
11	Always OFF

7.4.3 Protection Features

The TPLD2001 has some protection features including read/write protection for device configuration bits and CRC error detection on the internal OTP.

7.4.3.1 Device Read/Write Lock

The TPLD2001 implements lock features that enables device read-back protection for secure applications and prevents an accidental or unintended write to the TPLD2001 registers. There are three bits in the OTP that allows the user to define rules for reading and writing through the serial communications interface:

- **Configuration register (CFG) read lock:** the CFG read lock, if set, will block all read commands of the configuration registers through the serial communications interface and respond with 0's.
- **User register (USER) lock:** the USER lock consists of two bits and, depending on bit setting, will block write commands to the user register space through the serial communications interface to specific register addresses and any changes requested will be denied (no changes will be made to the configuration registers).

Registers & Access type	Lock bits				
	CFG RD lock = 0b0 USER lock = 0b00	CFG RD lock = 0b0 USER lock = 0b01	CFG RD lock = 0b0 USER lock = 0b10	CFG RD lock = 0b0 USER lock = 0b11	CFG RD lock = 0b1 USER lock = 0bXX
Device ID (0x000 - 0x003)	R	R	R	R	R
Program ID (0x004 - 0x007)	R	R	R	R	R

Registers & Access type	Lock bits				
Counter COUNT (0x010 - 0x01F)	R	R	R	R	—
Counter DATA (0x020 - 0x02F)	R/W	R/W	R	R	—
Watchdog Timer DATA (0x030 - 0x031)	R/W	R/W	R	R	—
Watchdog Timer Status (0x032)	R	R	R	R	R
Pattern Generator (0x040 - 0x041)	R/W	R/W	R	R	—
State Machine (0x050 - 0x05F)	R/W	R	R/W	R	—
Voltage Reference select for Analog Comparator (0x070 - 0x07F)	R/W	R	R	R/W	—
Virtual Input (0x0E0)	R/W	R/W	R/W	R/W	R/W
Virtual Output (0x0E1)	R	R	R	R	R
CRC Status (0x0FE)	R	R	R	R	R
Configuration Registers (0x200 - 0x3FF)	R	R	R	R	—

Any write commands that come to the device via the serial communications interface that are not blocked, based on the protection bits, will change the contents of the configuration register that mirror the OTP bits. These write commands will not change the OTP bits themselves, and a POR event will restore the register bits to original programmed contents of the OTP.

7.4.3.2 OTP Cyclic Redundancy Check (CRC)

Cyclic Redundancy Checks (CRCs) is a common method of performing error checking on areas of OTP and ensuring data integrity of this memory. OTP is used to configure the TPLD2001's macro-cells and connection mux routing. The OTP is one-time programmable and holds the device configuration data. OTP memory is loaded during device power up and transferred to TPLD2001 connection mux.

To ensure the bit integrity of the OTP memory before the stored configuration is loaded from OTP to device registers, as a safety measure, TPLD2001 implements a cyclic redundancy check (CRC) feature for the OTP to make sure that the data stored in the OTP is uncorrupted. At start-up, the OTP will be read internally and will check for a valid CRC. If the CRC is not valid, this process will be performed for a total of 7 more times. If still not valid after the 8th attempt, the device will proceed with loading the contents from OTP but set the following status bits:

CRC_ERR_CNT bits:

The CRC_ERR_CNT bits in register 0x0FEh [7:5] indicate the number of failed CRC attempts before loading the OTP contents into the configuration of the device. To reset the status bits to 0, issue a software reset command, or cycle power to the TPLD2001.

CRC_ERR_FLAG bit:

The CRC_ERR_FLAG bit in register 0x0FEh [0] indicates there were more than 8 CRC calculation failures in the loading of the OTP contents into the configuration of the device. To reset the status bits to 0, issue a software reset command, or cycle power to the TPLD2001.

7.4.4 Programming

The TPLD2001 is programmed through a I²C or SPI interface.

In the programmed case for the TPLD2001 device, the configuration choices made by the user are stored as bit settings in the OTP, and this information is transferred at startup time to connection mux registers that enable the configuration of the macro-cells and for setting the connections in the connection mux to route signals in the manner most appropriate for the user's application.

7.4.4.1 Selectable I²C/SPI Interface

In an unprogrammed TPLD2001 device, the Interface Select pin (IO1) is sampled at device power up to determine the interface the TPLD will boot up with after t_{SU} (max).

When the pin is tied to GND (logic low) or left floating, the TPLD2001 will be configured with a I²C interface with the first four bits of the target address determined by the respective HW Addr IO and the next three bits default to 001b, or ADDR = [A6][A5][A4][A3][0][0][1].

When the pin is tied to VCC (logic high), the TPLD2001 will be configured with a SPI interface.

In a programmed device (one in which the OTP has been burned), this setting will be overwritten by the selection stored in the OTP memory.

I ² C_EN	SPI_EN	Interface enabled
0	0	Device is unprogrammed (blank)
0	1	SPI
1	0	I ² C
1	1	Neither I ² C nor SPI, pins are GPIOs

7.4.4.2 One-Time Programmable Memory (OTP)

The TPLD2001 contains one-time programmable (OTP) memory bits. These memory bits retain the set values in the absence of a power supply, are used to configure the TPLD device, and can be programmed a maximum of one time. The default values for all the configuration registers in the TPLD2001 are loaded from OTP after a POR event is issued.

Procedure to temporarily set up configuration registers:

1. After starting up the device with the desired serial communications protocol, read the DEVICE_ID from registers 0x000 and 0x001 to ensure communication with the device has been established
2. Then:
 - a. For SPI, send the following four frames with at least 200µs between frames: 0x9000B9, 0x90003E, 0x9000AF, 0x900058
 - b. For I²C, in four write transactions, send the following with at least 500µs between transactions:
 - i. Transaction 1: BYTE0 = ADDR, BYTE1 = 0x01, BYTE2 = 0xB9
 - ii. Transaction 2: BYTE0 = ADDR, BYTE1 = 0x01, BYTE2 = 0x3E
 - iii. Transaction 3: BYTE0 = ADDR, BYTE1 = 0x01, BYTE2 = 0xAF
 - iv. Transaction 4: BYTE0 = ADDR, BYTE1 = 0x01, BYTE2 = 0x58
3. After the final frame is sent, wait 1ms.
4. Ensure you have entered configuration mode correctly by reading 0x10 from register 0x400.
5. Write 0x02 to register 0x400.

6. Send configuration bits to 0x200 - 0x3FF.
7. Optionally, after sending configuration bits, read commands can be used to verify the correct data was written to the device.
8. Then:
 - a. For SPI, send the following frame: 0x90004B
 - b. For I²C, send the following write transaction: BYTE0 = ADDR, BYTE1 = 01, BYTE2 = 0x4B
9. Lastly, write 0x00 to register 0x400 for the configuration to take effect.
10. Device is now temporarily configured.

Note

When temporarily configuring the TPLD with the I²C macro-cell enabled, the first four bits of the target address is set to 0000b and the next three bits will come from the configuration bits, or ADDR = [0][0][0][0][A2][A1][A0]. An OTP burn is necessary in order to change the first four bits, or MSB, of the target address.

To change the temporary configuration, it is recommended to power cycle the device and repeating the procedure to temporarily set up the configuration registers.

If the device is already temporarily configured with the I²C macro-cell enabled, writes to the I²C_ADDR register (SER_COMM_CFG1) will take immediate effect. Thus, subsequent I²C transactions need to be addressed to the updated target address.

Procedure to burn the OTP:

1. If the device has been temporarily configured, power cycle the device to clear configuration registers before continuing.
2. Follow steps 1 - 7 from the procedure to temporarily set up configuration registers.
3. Apply VPP to the GPI pin.
4. Write 0x01 to register 0x401 to start the OTP programming.
5. Wait 50ms for the programming to be complete.
6. Remove VPP from the GPI pin.
7. Device OTP is now burned.

7.4.4.3 Intel HEX File Format

InterConnect Studio generates the configuration bits in Intel HEX format. The .hex file can be parsed to extract the datastream to configure the TPLD device. The Intel HEX record, or line of text, structure is shown below.

Table 7-37. Record structure example

:	10	0200	00	000102030405060708090A0B0C0D0E0F	76
Start code	Byte count	Address	Record type	Data	Checksum

- **Start code:** one character, an ASCII colon (:).
- **Byte count:** two hex digits to indicate the number of bytes in the Data field.
- **Address:** four hex digits to represent the starting address offset of the first Data byte.
- **Record type:** two hex digits defining the meaning of the Data field. While Intel HEX has six standard record types, only two are used in the .hex file generation.
 - **Hex code 00:** indicates Data record type; the example record structure above results in a Byte count of 0x10 (16 bytes), starting Address of 0x0200, and Data (0x00, 0x01, 0x02, 0x03, 0x04, 0x05, 0x06, 0x07, 0x08, 0x09, 0x0A, 0x0B, 0x0C, 0x0D, 0x0E, and 0x0F).
 - **Hex code 01:** indicates an End of File record type; the Byte count is 0x00, the Address is typically 0x0000, and the Data field is omitted.
- **Data:** contains the sequence of *Byte count* bytes of data.

- **Checksum:** two hex digits computed by taking the summation of each byte preceding the Checksum and computing the two's complement of the sum's least significant byte. This value can be used to verify the record has no errors.

7.4.4.4 TPLD2001 Registers

The following section provides the registers accessible in the TPLD2001.

Note

Reads from and writes to the device may be asynchronous; thus current counter data may change by the time the read occurs depending on the speed of the clock used for the counter and of the serial communications interface.

7.4.4.4.1 TPLD2001_User Registers

Table 7-38 lists the memory-mapped registers for the TPLD2001_User registers. All register offset addresses not listed in Table 7-38 should be considered as reserved locations and the register contents should not be modified.

Table 7-38. TPLD2001_USER Registers

Offset	Acronym	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0h	DEVICE_ID0					DEVICE_ID_MSB

8 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The configurable logic and timing blocks of TPLD2001 allow for the device to provide symmetric power-up and power-down signals for numerous components. In this application the device is configured to output the maximum amount of power- up and power-down sequencing signals based on a counter/delay macro-cell.

8.2 Typical Application

Figure 8-1. Typical Application Block Diagram

8.2.1 Design Requirements

8.2.1.1 Power Considerations

Ensure the desired supply voltage is within the range specified in the *Recommended Operating Conditions*. The supply voltage sets the device's electrical characteristics of the device as described in the *Electrical Characteristics* section.

The positive voltage supply must be capable of sourcing current equal to the maximum static supply current, I_{CC} , listed in the *Electrical Characteristics*, and any transient current required for switching.

The ground must be capable of sinking current equal to the total current to be sunk by all outputs of the TPLD2001 plus the maximum supply current, I_{CC} , listed in the *Electrical Characteristics*, and any transient current required for switching. The logic device can only sink as much current that can be sunk into its ground connection. Ensure the maximum total current through GND listed in the *Absolute Maximum Ratings* is not exceeded.

The TPLD2001 can drive a load with a total capacitance less than or equal to 15pF while still meeting all of the data sheet specifications. Larger capacitive loads can be applied; however, it is not recommended to exceed 15pF.

The TPLD2001 can drive a load with total resistance described by $R_L \geq V_O / I_O$, with the output voltage and current defined in the *Electrical Characteristics* table with V_{OL} . When outputting in the HIGH state, the output voltage in the equation is defined as the difference between the measured output voltage and the supply voltage at the V_{CC} pin.

Total power consumption can be calculated using the information provided in [CMOS Power Consumption and Cpd Calculation](#).

Thermal increase can be calculated using the information provided in [Thermal Characteristics of Standard Linear and Logic \(SLL\) Packages and Devices](#).

CAUTION

The maximum junction temperature, $T_{J(max)}$ listed in the *Absolute Maximum Ratings*, is an additional limitation to prevent damage to the device. Do not violate any values listed in the *Absolute Maximum Ratings*. These limits are provided to prevent damage to the device.

8.2.1.2 Input Considerations

Input signals must cross to be considered a logic LOW, and to be considered a logic HIGH. Do not exceed the maximum input voltage range found in the *Absolute Maximum Ratings*.

Unused inputs must be terminated to either V_{CC} or ground. The unused inputs can be directly terminated if the input is completely unused, or they can be connected with a pull-up or pull-down resistor if the input will be used sometimes, but not always. A pull-up resistor is used for a default state of HIGH, and a pull-down resistor is used for a default state of LOW. The drive current of the controller, leakage current into the TPLD2001 (as specified in the *Electrical Characteristics*), and the desired input transition rate limits the resistor size. A $10k\Omega$ resistor value is often used due to these factors.

Refer to the *Feature Description* section for additional information regarding the inputs for this device.

8.2.1.3 Output Considerations

The ground voltage is used to produce the output LOW voltage. Sinking current into the output will increase the output voltage as specified by the V_{OL} specification in the *Electrical Characteristics*.

Unused outputs can be left floating. Do not connect outputs directly to V_{CC} or ground.

Refer to the *Feature Description* section for additional information regarding the outputs for this device.

8.2.2 Detailed Design Procedure

1. Add a decoupling capacitor from V_{CC} to GND. The capacitor needs to be placed physically close to the device and electrically close to both the V_{CC} and GND pins. An example layout is shown in the [Layout](#) section.
2. Verify that the capacitive load at the output is $\leq 50\text{pF}$. This is not a hard limit; by design, however, it will optimize performance. This can be accomplished by providing short, appropriately sized traces from the TPLD2001 to one or more of the receiving devices.
3. Verify that the resistive load at the output is larger than $(V_{CC} / I_{O(\text{max})})\Omega$. Doing this prevents the maximum output current from the [Absolute Maximum Ratings](#) from being violated. Most CMOS inputs have a resistive load measured in $M\Omega$; much larger than the minimum calculated previously.
4. Thermal issues are rarely a concern for logic gates; the power consumption and thermal increase, however, can be calculated using the steps provided in the [CMOS Power Consumption and Cpd Calculation](#) application note.

8.2.3 Application Curves

Figure 8-2. Application Timing Diagram

8.3 Power Supply Recommendations

The power supply can be any voltage between the minimum and maximum supply voltage rating located in the *Recommended Operating Conditions*. Each V_{CC} terminal should have a good bypass capacitor to prevent power disturbance.

A 0.1μF capacitor is recommended for this device. It is acceptable to parallel multiple bypass capacitors to reject different frequencies of noise. The 0.1μF and 1μF capacitors are commonly used in parallel. The bypass capacitor should be installed as close to the power terminal as possible for best results.

8.4 Layout

8.4.1 Layout Guidelines

When using multiple-input and multiple-channel logic devices, inputs must never be left floating. In many cases, functions or parts of functions of digital logic devices are unused; for example, when only two inputs of a triple-input AND gate are used or only 3 of the 4 buffer gates are used. Such unused input pins must not be left unconnected because the undefined voltages at the outside connections result in undefined operational states. All unused inputs of digital logic devices must be connected to a logic high or logic low voltage, as defined by the input voltage specifications, to prevent them from floating. The logic level that must be applied to any particular unused input depends on the function of the device. Generally, the inputs are tied to GND or V_{CC}, whichever makes more sense for the logic function or is more convenient.

8.4.2 Layout Example

9 Device and Documentation Support

9.1 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on [ti.com](#). Click on *Notifications* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

9.2 Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

9.3 Trademarks

TI E2E™ is a trademark of Texas Instruments.

All trademarks are the property of their respective owners.

9.4 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

9.5 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

10 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Date	Revision	Notes

PACKAGE OUTLINE

DGS0020A

VSSOP - 1.1 mm max height

SMALL OUTLINE PACKAGE

4226367/A 10/2020

NOTES:

PowerPAD is a trademark of Texas Instruments.

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm per side.
4. No JEDEC registration as of September 2020.
5. Features may differ or may not be present.

EXAMPLE BOARD LAYOUT

DGS0020A

VSSOP - 1.1 mm max height

SMALL OUTLINE PACKAGE

NOTES: (continued)

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature numbers SLMA002 (www.ti.com/lit/slma002) and SLMA004 (www.ti.com/lit/slma004).
9. Size of metal pad may vary due to creepage requirement.
10. Vias are optional depending on application, refer to device data sheet. It is recommended that vias under paste be filled, plugged or tented.

EXAMPLE STENCIL DESIGN

DGS0020A

PACKAGING INFORMATION

Orderable part number	Status (1)	Material type (2)	Package Pins	Package qty Carrier	RoHS (3)	Lead finish/ Ball material (4)	MSL rating/ Peak reflow (5)	Op temp (°C)	Part marking (6)
PTPLD2001DGSR	Active	Preproduction	VSSOP (DGS) 20	3000 LARGE T&R	-	Call TI	Call TI	-40 to 125	
PTPLD2001RJYR	Active	Preproduction	UQFN (RJY) 20	3000 LARGE T&R	-	Call TI	Call TI	-40 to 125	

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

8. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature numbers SLMA002 (www.ti.com/lit/slma002) and SLMA004 (www.ti.com/lit/slma004).
9. Size of metal pad may vary due to creepage requirement.
10. Vias are optional depending on application, refer to device data sheet. It is recommended that vias under paste be filled, plugged or tented.

EXAMPLE STENCIL DESIGN

DGS0020A

VSSOP - 1.1 mm max height

SMALL OUTLINE PACKAGE

SOLDER PASTE EXAMPLE
BASED ON 0.125 mm THICK STENCIL
SCALE: 16X

4226367/A 10/2020

NOTES: (continued)

11. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
12. Board assembly site may have different recommendations for stencil design.

IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATA SHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you will fully indemnify TI and its representatives against, any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to [TI's Terms of Sale](#) or other applicable terms available either on [ti.com](#) or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products.

TI objects to and rejects any additional or different terms you may have proposed.
