

ADC3561, ADC3562, ADC3563 SBAS990B - FEBRUARY 2021 - REVISED OCTOBER 2022

# ADC356x 16-Bit, 0.5-MSPS to 65-MSPS, Low-Noise, Low Power ADC

#### 1 Features

16-Bit 10-MSPS to 65-MSPS ADC

Noise floor: -158 dBFS/Hz

Low power consumption:

77 mW (10 MSPS) to 122 mW (65 MSPS)

Latency: 1 clock cycle (1-wire SLVDS)

Specified 16-bit, no missing codes

INL: ± 3 LSB; DNL: ± 0.7 LSB

Reference: external or internal

Input bandwidth: 900 MHz (3 dB)

Industrial temperature range: -40°C to +105°C

On-chip dual band digital filter (optional)

Decimation by 2, 4, 8, 16, 32

32-bit NCO

Serial LVDS digital interface (2-, 1- and 1/2-wire)

Small footprint: 40-WQFN (5 mm × 5 mm) package

Spectral performance ( $f_{IN} = 10 \text{ MHz}$ ):

SNR: 81.9 dBFS

SFDR: 95-dBc HD2, HD3 SFDR: 100-dBFS worst spur

### 2 Applications

**High-Speed Data Acquisition** 

**Industrial Monitoring** 

Software Defined Radio

Power Quality Analyzer

Source Measurement Unit (SMU)

Communications Infrastructure

Spectrum Analyzer

Control Loops

Instrumentation

**Imaging** 

Spectroscopy

Radar

Sonar

### 3 Description

The ADC3561, ADC3562, ADC3563 (ADC356x) family of devices are a low-noise, ultra-low power, 16-bit, 10-MSPS to 65-MSPS, high-speed analog-todigital converters (ADCs). Designed for low power consumption, these devices deliver a noise spectral density of -158 dBFS/Hz combined with excellent linearity and dynamic range. The ADC356x offers good DC precision together with IF sampling support making the device suitable for a wide range of applications. High-speed control loops benefit from the short latency of only one clock cycle. The ADC consumes only 122 mW at 65 MSPS and power consumption that scales well with lower sampling rates.

The ADC356x uses a serial LVDS (SLVDS) interface to output the data which minimizes the number of digital interconnects. The device supports two-, oneand half-lane options. The ADC356x and ADC358x are a pin-to-pin compatible family with 16 and 18-bit resolution and different speed grades. The devices come in a 40-pin QFN package (5 x 5 mm), and supports the extended industrial temperature range from -40 to +105°C.

#### **Package Information**

| PART NUMBER | PACKAGE <sup>(1)</sup> | BODY SIZE (NOM)   |  |  |
|-------------|------------------------|-------------------|--|--|
| ADC356x     | WQFN (40)              | 5.00 mm × 5.00 mm |  |  |

For all available packages, see the orderable addendum at the end of the data sheet.

Table 3-1. Device Comparison

| PART NUMBER | RESOLUTION     | SAMPLING RATE |  |  |  |
|-------------|----------------|---------------|--|--|--|
| ADC3563     | 16 BIT 65 MSPS |               |  |  |  |
| ADC3562     | 16 BIT         | 25 MSPS       |  |  |  |
| ADC3561     | 16 BIT         | 10 MSPS       |  |  |  |

# **4 Revision History**

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

# Changes from Revision A (October 2022) to Revision B (October 2022) Page Added mission TVP reliable of 0.42 % FOR for Onio Employed and ARCOSSA (40 MCRS)

| • | Added missing I | YP value of 0.43 % | FSR for Gain Err | or under ADC356 | 1 (10 MSPS) |  |
|---|-----------------|--------------------|------------------|-----------------|-------------|--|
|   |                 |                    |                  |                 |             |  |
|   |                 |                    |                  |                 |             |  |

| С | hanges from Revision * (February 2021) to Revision A (October 2022)  | Page |
|---|--|------|
| • | Removed the Product Preview note from part numbers ADC3561 and ADC3562 in the <i>Device Comparis</i> table |      |
| • | Corrected pin numbers for DB0P/M, DB1P/M, IOVDD and IOGND  |      |
|   | Added the Typical Characteristics - ADC3561 graphs   |      |
|   | Added the Typical Characteristics - ADC3562 graphs   |      |
|   | Added GND symbol to REFGND pin for all voltage reference option diagrams                                   |      |
|   | Added the section Output Bit Mapper  |      |

### **6 Specifications**

### 6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)(1)

| PARAMETER                     | TEST CONDITIONS                     | MIN  | MAX   | UNIT |
|-------------------------------|-------------------------------------|------|---|------|
| Supply voltage range          | e, AVDD, IOVDD                      | -0.3 | .3 2.1 V<br>.3 0.3 V<br>.3 MIN(2.1, AVDD+0.3) |      |
| Supply voltage range          | e, GND, IOGND, REFGND               | -0.3 | 0.3   | V    |
|                               | AINP/M, CLKP/M, VREF, REFBUF        | -0.3 | MIN(2.1, AVDD+0.3)                            |      |
| Voltage applied to input pins | PDN/SYNC, RESET, SCLK, SEN, SDIO    | -0.3 | MIN(2.1, AVDD+0.3)                            | V    |
| par pe                        | DCLKINP/M                           | -0.3 | MIN(2.1, IOVDD+0.3)                           |      |
| Junction temperature          | unction temperature, T <sub>J</sub> |      | °C  |      |
| Storage temperature           | e, T <sub>stg</sub>                 | -65  | 150   | °C   |

<sup>(1)</sup> Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

### 6.2 ESD Ratings

|                    |                         |  | VALUE | UNIT |
|--------------------|-------------------------|--|-------|------|
|                    |                         | Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins <sup>(1)</sup>              | 2500  |      |
| V <sub>(ESD)</sub> | Electrostatic discharge | Charged device model (CDM), per JEDEC specification JESD22-C101, all pins <sup>(2)</sup> | 1000  | V    |

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### **6.3 Recommended Operating Conditions**

over operating free-air temperature range (unless otherwise noted)

|                |                                | MIN  | NOM | MAX                | UNIT |
|----------------|--------------------------------|------|-----|--------------------|------|
| Supply         | AVDD <sup>(1)</sup>            | 1.75 | 1.8 | 1.85               | V    |
| voltage range  | IOVDD <sup>(1)</sup>           | 1.75 | 1.8 | 1.85               | V    |
| T <sub>A</sub> | Operating free-air temperature | -40  |     | 105                | °C   |
| T <sub>J</sub> | Operating junction temperature |      |     | 105 <sup>(2)</sup> | °C   |

- Measured to GND.
- (2) Prolonged use above this junction temperature may increase the device failure-in-time (FIT) rate.

#### 6.4 Thermal Information

|                       |   | ADC356x |      |
|-----------------------|---|---------|------|

### **8 Detailed Description**

#### 8.1 Overview

The ADC356x is a low noise, ultra-low power 16-bit high-speed single channel ADC supporting sampling rates up to 65 Msps. It offers very good DC precision together with IF sampling support which makes it ideally suited for a wide range of applications. The ADC356x is equipped with an on-chip internal reference option but it also supports the use of an external, high precision 1.6 V voltage reference or an external 1.2V reference which is buffered and gained up internally. Because of the inherent low latency architecture, the digital output result is available after only one to two clock cycles. Single ended as well as differential input signaling is supported.

An optional programmable digital down converter enables external anti-alias filter relaxation as well as output data rate reduction. An internal mux enables dual band complex decimation with independent NCO frequency tuning. The digital filter provides a 32-bit programmable NCO and supports both real or complex decimation.

The ADC356x family uses a serial LVDS (SLVDS) interface to output the data which minimizes the number of digital interconnects. The device supports a two-lane (2-wire), a one-lane (1-wire) and a half-lane (1/2-wire) option. The ADC356x includes a digital output formatter which supports output resolutions from 14 to 20-bit.

The device features and control options can be set up either through pin configurations or via SPI register writes.

### 8.2 Functional Block Diagram

#### 8.3 Feature Description

#### 8.3.1 Analog Input

The analog inputs of ADC356x are intended to be driven differentially. Both AC coupling and DC coupling of the analog inputs is supported. The analog inputs are designed for an input common mode voltage of 0.95 V which must be provided externally on each input pin. DC-coupled input signals must have a common mode voltage that meets the device input common mode voltage range.

The equivalent input network diagram is shown in Figure 8-1. All four sampling switches, on-resistance shown in red are in same position (open or closed) simultaneously.

Figure 8-1. Equivalent Input Network

### 8.3.1.1 Analog Input Bandwidth

Figure 8-2 shows the analog full power input bandwidth of the ADC356x with a 50  $\Omega$  differential termination. The -3 dB bandwidth is approximately 900 MHz and the useful input bandwidth with good AC performance is approximately 120 MHz.

The equivalent differential input resistance R<sub>IN</sub> and input capacitance C<sub>IN</sub> vs frequency are shown in Figure 8-3.

#### 8.3.1.2 Analog Front End Design

The ADC356x is an unbuffered ADC and thus a passive kick-back filter is recommended to absorb the glitch from the sampling operation. Depending on if the input is driven by a balun or a differential amplifier with low output impedance, a termination network may be needed. Additionally a passive DC bias circuit is needed in AC-coupled applications which can be combined with the termination network.

#### 8.3.1.2.1 Sampling Glitch Filter Design

The front end sampling glitch filter is designed to optimize the SNR and HD3 performance of the ADC. The filter performance is dependent on input frequency and therefore the following filter designs are recommended for different input frequency ranges as shown in Figure 8-4 and Figure 8-5.

Figure 8-4. Sampling glitch filter example for input frequencies from DC to 30 MHz

Figure 8-5. Sampling glitch filter example for input frequencies from 30 to 70 MHz

#### 8.3.1.2.2 Analog Input Termination and DC Bias

Depending on the input drive circuitry, a termination network and/or DC biasing needs to be provided.

#### 8.3.1.2.2.1 AC-Coupling

The ADC356x requires external DC bias using the common mode output voltage (VCM) of the ADC together with the termination network as shown in Figure 8-6. The termination is located within the glitch filter network. When using a balun on the input, the termination impedance has to be adjusted to account for the turns ratio of the transformer. When using an amplifier, the termination impedance can be adjusted to optimize the amplifier performance.

Figure 8-6. AC-Coupling: termination network provides DC bias (glitch filter example for DC - 30 MHz)

#### 8.3.1.2.2.2 DC-Coupling

In DC coupled applications the DC bias needs to be provided from the fully differential amplifier (FDA) using VCM output of the ADC as shown in Figure 8-7. The glitch filter in this case is located between the anti-alias filter and the ADC. No termination may be needed if amplifier is located close to the ADC or if the termination is part of the anti-alias filter.

Figure 8-7. DC-Coupling: DC bias provided by FDA (glitch filter example for DC - 30 MHz)

#### 8.3.1.3 Auto-Zero Feature

The ADC356x includes an internal auto-zero front end amplifier circuit which improves the 1/f flicker noise. This auto-zero feature is enabled by default for the ADC3561/2 and can be enabled using SPI register writes for the ADC3563 (register 0x11, D0). The 4M point FFTs below show the autozero feature enabled vs disabled.

#### 8.3.2 Clock Input

In order to maximize the ADC SNR performance, the external sampling clock should be low jitter and differential signaling with a high slew rate. This is especially important in IF sampling applications (Figure 8-14 and Figure 8-15). For less jitter sensitive applications, the ADC356x provides the option to operate with single ended signaling which saves additional power consumption.

#### 8.3.2.1 Single Ended vs Differential Clock Input

The ADC356x can be operated using a differential or a single ended clock input where the single ended clock consumes less power consumption. However clock amplitude impacts the ADC aperture jitter and consequently the SNR. For maximum SNR performance, a large clock signal with fast slew rates needs to be provided.

- Differential Clock Input: The clock input can be AC coupled externally. The ADC356x provides internal bias.
- Single Ended Clock Input: This mode needs to be configured using SPI register (0x0E, D2 and D0) or with the REFBUF pin. In this mode there is no internal clock biasing and thus the clock input needs to be DC coupled around a 0.9V center. The unused input needs to be AC coupled to ground.

Figure 8-16. External and internal connection using differential (left) and single ended (right) clock input

#### 8.3.2.2 Signal Acquisition Time Adjust

The ADC356x includes a register (DLL PDN (0x11, D2) which increases the signal acquisition time window for clock rates below 40 MSPS from 25% to 50% of the clock period. Increasing the sampling time provides a longer time for the driving amplifier to settle out the signal which can improve the SNR performance of the system. This register should only be used for the 65 MSPS speed grade (ADC3563) For the 10 and 25 MSPS device speed grades the sampling time is already set to TS/2. When powering down the DLL, the acquisition time will track the clock duty cycle (50% is recommended).

Table 8-1. Acquisition time vs DLL PDN setting

|                                      | · · · · · · · · · · · · · · · · · · · |                                      |
|--------------------------------------|---------------------------------------|--------------------------------------|
| SAMPLING CLOCK F <sub>S</sub> (MSPS) | DLL PDN (0x11, D2)                    | ACQUISITION TIME (t <sub>ACQ</sub> ) |
| 65                                   | 0                                     | T <sub>S</sub> / 4                   |
| ≤ 40                                 | 1                                     | T <sub>S</sub> / 2                   |

#### 8.3.3 Voltage Reference

The ADC356x provides three different options for supplying the voltage reference to the ADC. An external 1.6V reference can be directly connected to the VREF input; a voltage 1.2V reference can be connected to the REFBUF input using the internal gain buffer or the internal 1.2V reference can be enabled to generate a 1.6V reference voltage. For best performance, the reference noise should be filtered by connecting a 10 uF and a 0.1 uF ceramic bypass capacitor to the VREF pin. The internal reference circuitry of the ADC356x is shown in Figure 8-17.

#### Note

The voltage reference mode can be selected using SPI writes or by using the REFBUF pin (default) as a control pin (Configuration using PINs only). If the REFBUF pin is not used for configuration, the REFBUF pin should be connected to AVDD (even though the REFBUF pin has a weak internal pullup to AVDD) and the voltage reference option has to be selected using the SPI interface.

Figure 8-17. Different voltage reference options for ADC356x

#### 8.3.3.1 Internal voltage reference

The 1.6V reference for the ADC can be generated internal using the on-chip 1.2V reference along with the internal gain buffer. A 10 uF and a 0.1 uF ceramic bypass capacitor ( $C_{VREF}$ ) should be connected between the VREF and REFGND pins as close to the pins as possible.

Figure 8-18. Internal reference

#### 8.3.3.2 External voltage reference (VREF)

For highest accuracy and lowest temperature drift, the VREF input can be directly connected to an external 1.6V reference. A 10 uF and a 0.1 uF ceramic bypass capacitor ( $C_{VREF}$ ) connected between the VREF and REFGND pins and placed as close to the pins as possible is recommended. The load current from the external reference is about 1mA.

Note: The internal reference is also used for other functions inside the device, therefore the reference amplifier should only be powered down in power down state but not during normal operation.

Figure 8-19. External 1.6V reference

#### 8.3.3.3 External voltage reference with internal buffer (REFBUF)

The ADC356x is equipped with an on-chip reference buffer that also includes gain to generate the 1.6V reference voltage from an external 1.2V reference. A 10 uF and a 0.1 uF ceramic bypass capacitor ( $C_{VREF}$ ) between the VREF and REFGND pins and a 10 uF and a 0.1 uF ceramic bypass capacitor between the REFBUF and REFGND pins are recommended. Both capacitors should be placed as close to the pins as possible. The load current from the external reference is less than 100uA.

Figure 8-20. External 1.2V reference using internal reference buffer

#### 8.3.4 Digital Down Converter

The ADC356x includes an optional on-chip digital down conversion (DDC) decimation filter that can be enabled via SPI register settings. It supports complex decimation by 2, 4, 8, 16 and 32 using a digital mixer and a 32-bit numerically controlled oscillator (NCO) as shown in Figure 8-21. Furthermore it supports a mode with real decimation where the complex mixer is bypassed (NCO should be set to 0 for lowest power consumption) and the digital filter acts as a low pass filter.

Internally the decimation filter calculations are performed with a 20-bit resolution in order to avoid any SNR degradation due to quantization noise. The Output Formatter truncates to the selected resolution prior to outputting the data on the digital interface.

Figure 8-21. Internal Digital Decimation Filter

#### 8.3.4.1 DDC MUX for Dual Band Decimation

The ADC356x contains a MUX in front of the digital decimation filter which allows the ADC to be connected to two digital down converters (see Figure 8-22). This enables dual band complex decimation. The NCO of each digital down converter can be tuned to an independent frequency across the Nyquist zone as illustrated in the example in Figure 8-23. The second DDC is output using the DB0/1 SLVDS interface.

Figure 8-22. DDC MUX

Figure 8-23. Complex Decimation (by 8) with dual band illustration

#### 8.3.4.2 Digital Filter Operation

The complex decimation operation is illustrated with an example in Figure 8-24. First the input signal (and the negative image) are frequency shifted by the NCO frequency as shown on the left. Next a digital filter is applied (centered around 0 Hz) and the output data rate is decimated - in this example the output data rate  $F_{S,OUT} = F_S/8$  with a Nyquist zone of  $F_S/16$ . During the complex mixing the spectrum (signal and noise) is split into real and complex parts and thus the amplitude is reduced by 6-dB. In order to compensate this loss, there is a 6-dB digital gain option in the decimation filter block that can be enabled via SPI write.

Figure 8-24. Complex decimation illustration

The real decimation operation is illustrated with an example in Figure 8-25. There is no frequency shift happening and only the real portion of the complex digital filter is exercised. The output data rate is decimated a decimation of 8 would result in an output data rate  $F_{S,OUT} = F_S/8$  with a Nyquist zone of  $F_S/16$ .

During the real mixing the spectrum (signal and noise) amplitude is reduced by 3-dB. In order to compensate this loss, there is a 3-dB digital gain option in the decimation filter block that can be enabled via SPI write.

Figure 8-25. Real decimation illustration

#### 8.3.4.3 FS/4 Mixing with Real Output

In this mode, the output after complex decimation gets mixed with FS/4 (FS = output data rate in this case). Instead of a complex output with the input signal centered around 0 Hz, the output is transmitted as a real output at twice the data rate and the signal is centered around FS/4 (Fout/4) as illustrated in Figure 8-26.

In this example, complex decimation by 8 is used. The output data is transmitted as a real output with an output rate of Fout = FS'/4 (FS' = ADC sampling rate). The input signal is now centered around FS/4 (Fout/4) or FS'/16.

Figure 8-26. FS/4 Mixing with real output

### 8.3.4.4 Numerically Controlled Oscillator (NCO) and Digital Mixer

The decimation block is equipped with a 32-bit NCO and a digital mixer to fine tune the frequency placement prior to the digital filtering. The oscillator generates a complex exponential sequence of:

$$e^{j\omega n}$$
 (default) or  $e^{-j\omega n}$  (1)

where: frequency ( $\omega$ ) is specified as a signed number by the 32-bit register setting

The complex exponential sequence is multiplied with the real input from the ADC to mix the desired carrier to a frequency equal to  $f_{\text{IN}}$  +  $f_{\text{NCO}}$ . The NCO frequency can be tuned from  $-F_{\text{S}}/2$  to  $+F_{\text{S}}/2$  and is processed as a signed, 2s complement number. After programming a new NCO frequency, the MIXER RESTART register bit or SYNC pin has to be toggled for the new frequency to get active. Additionally the ADC356x provides the option via SPI to invert the mixer phase.

The NCO frequency setting is set by the 32-bit register value given and calculated as:

NCO frequency = 0 to + 
$$F_S/2$$
: NCO =  $f_{NCO} \times 2^{32} / F_S$ 

NCO frequency = 
$$-F_S/2$$
 to 0: NCO =  $(f_{NCO} + F_S) \times 2^{32} / F_S$ 

#### where:

- NCO = NCO register setting (decimal value)
- f<sub>NCO</sub> = Desired NCO frequency (MHz)
- F<sub>S</sub> = ADC sampling rate (MSPS)

The NCO programming is further illustrated with this example:

- ADC sampling rate F<sub>S</sub> = 65 MSPS
- Input signal f<sub>IN</sub> = 10 MHz
- Desired output frequency f<sub>OUT</sub> = 0 MHz

For this example there are actually four ways to program the NCO and achieve the desired output frequency as shown in Table 8-2.

Table 8-2. NCO value calculations example

Alias or negative image  $f_{NCO}$  NCO Value Mixer Phase Frequency translation for  $f_{OUT}$   $f_{IN} = -10 \text{ MHz}$   $f_{NCO} = 10 \text{ MHz}$  660764199  $f_{OUT} = f_{IN} + f_{NCO} = -10 \text{ MHz} + 10 \text{ MHz} = 0$

#### 8.3.4.5 Decimation Filter

The ADC356x supports complex decimation by 2, 4, 8, 16 and 32 with a pass-band bandwidth of  $\sim$  80% and a stopband rejection of at least 85 dB. Table 8-3 gives an overview of the pass-band bandwidth of the different decimation settings with respect to ADC sampling rate  $F_S$ . In real decimation mode the output bandwidth is half of the complex bandwidth.

| REAL/COMPLEX DECIMATION SETTING N |    | OUTPUT RATE                 | OUTPUT<br>BANDWIDTH       | OUTPUT RATE<br>(F <sub>S</sub> = 65 MSPS) | OUTPUT BANDWIDTH<br>(F <sub>S</sub> = 65 MSPS) |
|-----------------------------------|----|-----------------------------|---------------------------|---|--|
|                                   | 2  | F <sub>S</sub> / 2 complex  | 0.8 × F <sub>S</sub> / 2  | 32.5 MSPS complex                         | 26 MHz   |
|                                   | 4  | F <sub>S</sub> / 4 complex  | 0.8 × F <sub>S</sub> / 4  | 16.25 MSPS complex                        | 13 MHz   |

|                                   | 32 | F <sub>S</sub> / 32 complex | 0.8 × F <sub>S</sub> / 32 | 2.03125 MSPS complex                      | 1.625 MHz                                      |
|                                   | 2  | F <sub>S</sub> / 2 real     | 0.4 × F <sub>S</sub> / 2  | 32.5 MSPS                                 | 13 MHz   |
|                                   | 4  | F <sub>S</sub> / 4 real     | 0.4 × F <sub>S</sub> / 4  | 16.25 MSPS                                | 6.5 MHz  |
| Real                              | 8  | F <sub>S</sub> / 8 real     | 0.4 × F <sub>S</sub> / 8  | 8.125 MSPS                                | 3.25 MHz                                       |
|                                   | 16 | F <sub>S</sub> / 16 real    | 0.4 × F <sub>S</sub> / 16 | 4.0625 MSPS                               | 1.625 MHz                                      |
|                                   | 32 | F <sub>S</sub> / 32 real    | 0.4 × F <sub>S</sub> / 32 | 2.03125 MSPS                              | 0.8125 MHz                                     |

The decimation filter responses are normalized to the ADC sampling clock frequency F<sub>S</sub> and illustrated in Figure 8-28 to Figure 8-37. They are interpreted as follows:

Each figure contains the filter pass-band, transition band(s) and alias or stop-band(s) as shown in Figure 8-27. The x-axis shows the offset frequency (after the NCO frequency shift) normalized to the ADC sampling rate F<sub>S</sub>.

For example, in the divide-by-4 complex setup, the output data rate is  $F_S$  / 4 complex with a Nyquist zone of  $F_S$  / 8 or 0.125 ×  $F_S$ . The transition band (colored in blue) is centered around 0.125 ×  $F_S$  and the alias transition band is centered at 0.375 ×  $F_S$ . The stop-bands (colored in red), which alias on top of the pass-band, are centered at 0.25 ×  $F_S$  and 0.5 ×  $F_S$ . The stop-band attenuation is greater than 85 dB.

Figure 8-27. Interpretation of the Decimation Filter Plots

#### 8.3.4.6 SYNC

The PDN/SYNC pin can be used to synchronize multiple devices using an external SYNC signal. The PDN/SYNC pin can be configured via SPI (SYNC EN bit) from power down to synchronization functionality and is latched in by the rising edge of the sampling clock as shown in Figure 8-38.

Figure 8-38. External SYNC timing diagram

The synchronization signal is only required when using the decimation filter - either using the SPI SYNC register or the PDN/SYNC pin. It resets internal clock dividers used in the decimation filter and aligns the internal clocks as well as I and Q data within the same sample. If no SYNC signal is given the internal clock dividers will not be synchronized, which can lead to a fractional delay across different devices. The SYNC signal also resets the NCO phase and loads the new NCO frequency (same as the MIXER RESTART bit).

When trying to resynchronize during operation, the SYNC toggle should occur at 64\*K clock cycles, where K is an integer. This ensures phase continuity of the clock divider.

## 8.3.4.7 Output Formatting with Decimation

When using decimation, the output data is formatted as shown in Figure 8-39 (complex decimation) and Figure 8-40 (real decimation).

Figure 8-39. Output Data Format in Complex Decimation

Table 8-4 illustrates the output interface data rate along with the corresponding DCLK/DCLKIN and FCLK frequencies based on output resolution (R), number of SLVDS lanes (L) and complex decimation setting (N).

Furthermore the table shows an actual lane rate example for the 2-, 1- and 1/2-wire interface, 16-bit output resolution and complex decimation by 4.

Table 8-4. Serial LVDS Lane Rate Examples with Complex Decimation and 16-bit Output Resolution

|  | DECIMATION SETTING | ADC SAMPLING<br>RATE | OUTPUT<br>RESOLUTION | # of WIRES | FCLK              | DCLKIN, DCLK  | DA/B0,1                    |
|--|--------------------|----------------------|----------------------|------------|-------------------|---------------|----------------------------|
|  | N                  | F <sub>S</sub>       | R                    | L          | F <sub>S</sub> /N | [DA/B0,1] / 2 | F <sub>S</sub> x 2 x R/L/N |

#### 8.3.5 Digital Interface

The serial LVDS interface supports the data output with 2-wire, 1-wire and 1/2-wire operation. The actual data output rate depends on the output resolution and number of lanes used.

The ADC356x requires an external serial LVDS clock input (DCLKIN), which is used to transmit the data out of the ADC along with the data clock (DCLK). The phase relationship between DCLKIN and the sampling clock is irrelevant but both clocks need to be frequency locked. The SLVDS interface is configured using SPI register writes.

#### 8.3.5.1 Output Formatter

The digital output interface utilizes a flexible output bit mapper as shown in Figure 8-41. The bit mapper takes the 16bit output directly from the ADC or from digital filter block and reformats it to a resolution of 14, 16, 18 or 20-bit. With parallel output format the maximum output resolution supported is 16-bit. With serial LVDS output the output serialization factor gets adjusted accordingly for 2-, 1- and 1/2-wire interface mode. The maximum output data rate can not be exceeded independently of output resolution and serialization factor.

With 14-bit output resolution the 2 LSBs are truncated.

Figure 8-41. Interface output bit mapper

Table 8-6 provides an overview for the resulting serialization factor depending on output resolution and output modes. Note that the DCLKIN frequency needs to be adjusted accordingly as well. Changing the output resolution to 14-bit, 2-wire mode for example would result in DCLKIN =  $F_S$  \* 3.5 instead of \* 4.

The output bit mapper can be used for bypass and decimation filter.

Table 8-6. Serialization Factor vs Output Resolution for Different Output Modes

The programming sequence to change the output interface and/or resolution from default settings is shown in Output Interface/Mode Configuration.

## 8.3.5.2 Output Bit Mapper

The output bit mapper allows change to the output bit order for any selected interface mode.

Figure 8-42. Output Bit Mapper

There is a two step process to change the output bit mapping and assemble the output data bus:

- 1. Both channel A and B can have up to 20-bit output. Each output bit of either channel has a unique identifier bit as shown in Table 8-7. The MSB starts with bit D19 depending on output resolution chosen the LSB would be D6 (14-bit) to D0 (20-bit). The 'previous sample' is only needed in 2-w mode.
- 2. The bit mapper is then used to assemble the output sample. The following sections detail how to remap the serial output format.

| Table 8-7. Unique identifier of each data bit |                           |                |                           |                |  |  |  |  |  |
|---|---------------------------|----------------|---------------------------|----------------|--|--|--|--|--|
| Bit   | Chan                      | nel A          | Chan                      | nel B          |  |  |  |  |  |
|   | Previous sample (2w only) | Current sample | Previous sample (2w only) | Current sample |  |  |  |  |  |
| D19 (MSB)                                     | D19 (MSB) 0x2D 0x6D       |                | 0x29                      | 0x69           |  |  |  |  |  |

Table 8-7. Unique identifier of each data bit

In the serial output mode, a data bit (with unique identifier) needs to be assigned to each location within the serial output stream. There are a total of 40 addresses available per channel. Channel A spans from address 0x39 to 0x60 and channel B from address 0x61 to 0x88. When using complex decimation, the output bit mapper is applied to both the "I" and the "Q" sample.

**2-wire mode**: in this mode both the current and the previous sample have to be used in the address space as shown in Figure 8-43. The address order is different for 14/18-bit and 16/20-bit. Note: there are unused addresses between samples for resolution less than 20-bit (gray back ground), which can be ignored if not used.

Figure 8-43. 2-wire output bit mapper

In the following example (Figure 8-44), the 16-bit 2-wire serial output is reordered to where lane DA1/DB1 carries the 8 MSB and lane DA0/DB0 carries 8 LSBs.

|     | Previous Sample                    |                                    |                                   |                                   |                                   |                                   |                                   | Current Sample                    |                                    |                                    |                                   |                                   |                                   |                                   |                                   |                  |

Figure 8-44. Example: 2-wire output bit mapping

**1-wire mode**: Only the 'current' sample needs to programmed in the address space. If desired, it can be duplicated on DA1/DB1 as well (using addresses shown below) in order to have a redundant output. Lane DA1/DB1 needs to be powered up in that case.

Figure 8-45. 1-wire output bit mapping

1/2-wire mode: The output is only lane DA0 and the sample order is programmed into the 40 addresses of chA (from 0x39 to 0x60). It covers 2 samples (one for chA, one for chB) as shown below. If desired, it can be duplicated on DB0 as well (using addresses shown Figure 8-46) in order to have a redundant output. Lane DB0 needs to be powered up in that case.

Figure 8-46. 1/2-wire output bit mapping

### 8.3.5.3 Output Scrambler

The device includes an optional output scrambler feature. Scrambling is performed on each serial output lane independently. When enabled, the serial output bit stream is scrambled where each output bit is XOR-ed with 2 previous bits (k-14 and k-15) as shown in Figure 8-47. For descrambling, note that the output bit mapper is located after the scrambler.

On the external receiver, the incoming serial data stream can be descrambled by XOR-ing each incoming bit with 2 previous bits (k-14 and k-15).

Figure 8-47. Output scrambling per lane

Figure 8-48. Output scrambler and descrambler operation

Scrambling is enabled by disabling digital bypass (register 0x24, D2) and enabling scrambling (register 0x22, D6).

## 8.3.5.4 Output Interface/Mode Configuration

The following sequence summarizes all the relevant registers for changing the output interface and/or enabling the decimation filter. Steps 1 and 2 must come first since the E-Fuse load reset the SPI writes, the remaining steps can come in any order.

Table 8-8. Configuration steps for changing interface or decimation

| OTED | FEATURE              |                          | Configuration s   | steps for change                                 |                        | aecimation            |                    |  |  |

#### 8.3.5.4.1 Configuration Example

The following is a step by step programming example to configure the ADC356x to complex decimation by 8 with 1-wire SLVDS and 16-bit output.

- 1. 0x07 (address) 0x6C (load bit mapper configuration for 16-bit output with 1-wire SLVDS)
- 2. 0x13 0x01, wait 1 ms, 0x13 0x00 (load e-fuse)
- 3. 0x19 0x80 (configure FCLK)
- 4. 0x1B 0x88 (select 16-bit output resolution)
- 5. 0x20 0xFF, 0x21 0xFF, 0x22 0x0F (configure FCLK pattern)
- 6. 0x24 0x06 (enable decimation filter)
- 7. 0x25 0x30 (configure complex decimation by 8)
- 8. 0x2A/B/C/D and 0x31/32/33/34 (program NCO frequency)
- 9. 0x27/0x2E 0x08 (configure Q-delay register bit)
- 10. 0x26 0xAA, 0x26 0x88 (set digital mixer gain to 6-dB and toggle the mixer update)

#### 8.3.5.5 Output Data Format

The output data can be configured to two's complement (default) or offset binary formatting using SPI register writes (register 0x8F and 0x92). Table 8-9 provides an overview for minimum and maximum output codes for the two formatting options. The actual output resolution is set by the output bit mapper.

Table 8-9. Overview of minimum and maximum output codes vs output resolution for different formatting

|                     | ٦                                 | īwo's Comple | ment (default   | t)      | Offset Binary |        |         |         |  |

#### 8.3.6 Test Pattern

In order to enable in-circuit testing of the digital interface, the following test patterns are supported and enabled via SPI register writes (0x14/0x15/0x16). The test pattern generator is located after the decimation filter as shown in Figure 8-49. In decimation mode (real and complex), the test patterns replace the output data of the DDC - however channel A controls the test patterns for both channels.

Figure 8-49. Test Pattern Generator

- RAMP Pattern: The step size needs to be configured in the CUSTOM PAT register according to the native resolution of the ADC. When selecting a higher output resolution then the additional LSBs will still be 0 in RAMP pattern mode.
  - 00001: 18-bit output resolution
  - 00100: 16-bit output resolution
  - 10000: 14-bit output resolution
- Custom Pattern: Configured in the CUSTOM PAT register

#### 8.4 Device Functional Modes

#### 8.4.1 Normal operation

In normal operating mode, the entire ADC full scale range gets converted to a digital output with 16-bit resolution. The output is available in as little as 1 clock cycle on the digital SLVDS outputs.

#### 8.4.2 Power Down Options

A global power down mode can be enabled via SPI as well as using the power down pin (PDN/SYNC). There is an internal pull-down  $21k\Omega$  resistor on the PDN/SYNC input pin and the pin is active high - so the pin needs to be pulled high externally to enter global power down mode.

The SPI register map provides the capability to enable/disable individual blocks directly or via PDN pin mask in order to trade off power consumption vs wake up time.

Figure 8-50. Power Down Configurations

**Table 8-10. Overview of Power Down Options** 

| Function/ Register       | PDN<br>via SPI | Mask for<br>Global PDN | Feature -<br>Default | Power<br>Impact      | Wake-up time | Comment   |

#### 8.5 Programming

The device is primarily configured and controlled using the serial programming interface (SPI) however it can operate in a default configuration without requiring the SPI interface. Furthermore the power down function as well as internal/external reference configuration is possible via pin control (PDN/SYNC and REFBUF pin).

Note

The power down command (via PIN or SPI) only goes in effect with the ADC sampling clock present.

After initial power up, the default operating configuration for each device is shown in Table 8-11.

Table 8-11. Default device configuration after power up

| FEATURE       | ADC3561                | ADC3562    | ADC3563  |  |  |  |  |
|---------------|------------------------|------------|----------|--|--|--|--|
| Signal Input  | Differential           |            |          |  |  |  |  |
| Auto-Zero     | Enabled                | Enabled    | Disabled |  |  |  |  |
| Clock Input   | Differential  External |            |          |  |  |  |  |

| Output Format | 2s complement          |            |          |  |  |  |  |

### 8.5.1 Configuration using PINs only

The ADC voltage reference can be selected using the REFBUF pin. Even though there is an internal 100 k $\Omega$  pull-up resistor to AVDD, the REFBUF pin should be set to a voltage externally and not left floating. When using a voltage divider to set the REFBUF voltage (R1 and R2 in Figure 8-51), resistor values < 5 k $\Omega$  should be used.

Figure 8-51. Configuration of external voltage on REFBUF pin

Table 8-12. REFBUF voltage levels control voltage reference selection

| REFBUF VOLTAGE     | VOLTAGE REFERENCE OPTION                                     | CLOCKING OPTION   |  |  |  |  |  |  |
|--------------------|--|---|--|--|--|--|--|--|
| > 1.7 V (Default)  | External reference   | Differential clock input  |  |  |  |  |  |  |

## 8.5.2 Configuration using the SPI interface

The device has a set of internal registers that can be accessed by the serial interface formed by the SEN (serial interface enable), SCLK (serial interface clock) and SDIO (serial interface data input/output) pins. Serially shifting bits into the device is enabled when SEN is low. Serial data input are latched at every SCLK rising edge when SEN is active (low). The serial data are loaded into the register at every 24th SCLK rising edge when SEN is low. When the word length exceeds a multiple of 24 bits, the excess bits are ignored. Data can be loaded in multiples of 24-bit words within a single active SEN pulse. The interface can function with SCLK frequencies from 12 MHz down to very low speeds (of a few hertz) and also with a non-50% SCLK duty cycle.

### 8.5.2.1 Register Write

The internal registers can be programmed following these steps:

- 1. Drive the SEN pin low
- 2. Set the R/W bit to 0 (bit A15 of the 16-bit address) and bits A[14:12] in address field to 0.
- 3. Initiate a serial interface cycle by specifying the address of the register (A[11:0]) whose content is written and
- 4. Write the 8-bit data that are latched in on the SCLK rising edges

Figure 8-52 show the timing requirements for the serial register write operation.

Figure 8-52. Serial Register Write Timing Diagram

### 8.5.2.2 Register Read

The device includes a mode where the contents of the internal registers can be read back using the SDIO pin. This readback mode can be useful as a diagnostic check to verify the serial interface communication between the external controller and the ADC. The procedure to read the contents of the serial registers is as follows:

- 1. Drive the SEN pin low
- 2. Set the R/W bit (A15) to 1. This setting disables any further writes to the registers. Set A[14:12] in address field to 0.
- 3. Initiate a serial interface cycle specifying the address of the register (A[11:0]) whose content must be read
- 4. The device launches the contents (D[7:0]) of the selected register on the SDIO pin on SCLK falling edge
- 5. The external controller can capture the contents on the SCLK rising edge

Figure 8-53. Serial Register Read Timing Diagram

# 8.6 Register Maps

Table 8-13. Register Map Summary

### Table 8-15. Register 0x07 Field Descriptions

|     | Tubic o      | rieid Descriptions |       |   |
|-----|--------------|--------------------|-------|---|
| Bit | Field        | Туре               | Reset | Description   |
| 7-5 | OP IF MAPPER | R/W                | 000   | Output interface mapper. This register contains the proper output interface bit mapping for the different interfaces. The interface bit mapping is internally loaded from e-fuses and also requires a fuse load command to go into effect (0x13, D0). Register 0x07 along with the E-Fuse Load (0x13, D0) needs to be loaded first in the programming sequence since the E-Fuse load resets the SPI writes.  After initial reset the default output interface variant is loaded automatically from fuse internally. However when reading back this register reads 000 until a value is written using SPI. 001: 2-wire, 18 and 14-bit 010: 2-wire, 16-bit 011: 1-wire 100: 0.5-wire others: not used |
| 4   | 0            | R/W                | 0     | Must write 0  |
| 3   | OP IF EN     | R/W                | 0     | Enables changing the default output interface mode (D2-D0).   |
| 2-0 | OP IF SEL    | R/W                | 000   | Selection of the output interface mode. OP IF EN (D3) needs to be enabled also.  After initial reset the default output interface is loaded automatically from fuse internally. However when reading back this register reads 000 until a value is written using SPI.  011: 2-wire 100: 1-wire 101: 0.5-wire others: not used   |

# Table 8-23. Register 0x19 Field Descriptions

| Bit | Field          | Туре               | Reset | Description   |
|-----|----------------|--------------------|-------|---|
| 7   | FCLK SRC       | R/W                | 0     | User has to select if FCLK signal comes from ADC or from DDC block. Here real decimation is treated same as bypass mode 0: FCLK generated from ADC. FCLK SRC set to 0 for DDC bypass, real decimation mode and 1/2-w complex decimation mode.  1: FCLK generated from DDC block. In complex decimation mode only this bit needs to be set for 2-w and 1-w output interface mode but NOT for 1/2-w mode. |
| 6-5 | 0              | R/W 0 Must write 0 |       | Must write 0  |
| 4   | FCLK DIV       | R/W                | 0     | This bit needs to be set to 1 for 2-w output mode in bypass mode only (non decimation).  0: All output interface modes except 2-w bypass mode.  1: 2-w output interface mode.   |
| 3-1 | 0              | R/W                | 0     | Must write 0  |
| 0   | TOG FCLK R/W 0 |                    | 0     | This bit adjusts the FCLK signal appropriately for 1/2-wire mode where FCLK is stretched to cover channel A and channel B. This bit ONLY needs to be set in 1/2-wire mode with complex decimation mode.  0: all other modes.  1: FCLK for 1/2-wire complex decimation mode.   |

# Table 8-24. Configuration of FCLK SRC and FCLK DIV Register Bits vs Serial Interface

# 9 Application Information Disclaimer

#### Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

### 9.1 Typical Application

A spectrum analyzer is a typical frequency domain application for the ADC356x and its front end circuitry is very similar to several other systems such as software defined radio (SDR), sonar, radar or communications. Some applications require frequency coverage including DC or near DC (such as. sonar), so it is included in this example.

Figure 9-1. Typical configuration for a spectrum analyzer with DC support

### 9.1.1 Design Requirements

Frequency domain applications cover a wide range of frequencies from low input frequencies at or near DC in the 1st Nyquist zone to under sampling in higher Nyquist zones. If very low input frequency is supported then the input has to be DC coupled and the ADC driven by a fully differential amplifier (FDA). If low frequency support is not needed, then AC coupling and use of a balun may be more suitable.

The internal reference is used since DC precision is not needed. However the ADC AC performance is highly dependent on the quality of the external clock source. If in-band interferes can be present, then the ADC SFDR performance will be a key care about as well. A higher ADC sampling rate is desirable in order to relax the external anti-aliasing filter – an internal decimation filter can be used to reduce the digital output rate afterwards.

Table 9-1. Design key care-abouts

| FEATURE          | DESCRIPTION  |  |
|------------------|--|--|
| Signal Bandwidth | DC to 20 MHz   |  |
| Input Driver     | Single ended to differential signal conversion and DC coupling |  |
| Clock Source     | External clock with low jitter                                 |  |

When designing the amplifier/filter driving circuit, the ADC input full-scale voltage needs to be taken into consideration. For example, the ADC356x input full-scale is 3.2 Vpp. When factoring in ~ 1 dB for insertion loss of the filter, then the amplifier needs to deliver close to 3.6 Vpp. The amplifier distortion performance will degrade

with a larger output swing and considering the ADC common mode input voltage the amplifier may not be able to deliver the full swing. The ADC356x provides an output common mode voltage of 0.95 V and the THS4541 for example can only swing within 250 mV of its negative supply. A unipolar 3.3 V amplifier power supply will thus limit the maximum voltage swing to ~ 2.8 Vpp. Hence if a larger output swing is required (factoring in filter insertion loss) then a negative supply for the amplifier is needed in order to eliminate that limitation. Additionally input voltage protection diodes may be needed to protect the ADC from over-voltage events.

Table 9-2. Output voltage swing of THS4541 vs power supply

| DEVICE  | MIN OUTPUT VOLTAGE | MAX SWING WITH 3.3 V/ 0 V SUPPLY | MAX SWING WITH 3.3 V/ -1 V SUPPLY |  |
|---------|--------------------|----------------------------------|-----------------------------------|--|
| THS4541 | VS- + 250 mV       | 2.8 Vpp                          | 6.8 Vpp                           |  |

## 9.1.2 Detailed Design Procedure

#### 9.1.2.1 Input Signal Path

Depending on desired input signal frequency range the THS4551 and THS4541 provide very good low power options to drive the ADC inputs. Table 9-3 provides a comparison between the THS4551 and THS4541 and the power consumption vs usable frequency trade off.

**Table 9-3. Fully Differential Amplifier Options** 

| DEVICE  | CURRENT (IQ) PER CHANNEL | USABLE FREQUENCY RANGE |  |
|---------|--------------------------|------------------------|--|
| THS4561 | 0.8 mA                   | < 3 MHz                |  |
| THS4551 | 1.4 mA                   | < 10 MHz               |  |
| THS4541 | 10 mA                    | < 70 MHz               |  |

The low pass filter design (topology, filter order) is driven by the application itself. However, when designing the low pass filter, the optimum load impedance for the amplifier should be taken into consideration as well. Between the low pass filter and the ADC input the sampling glitch filter needs to added as well as shown in Sampling Glitch Filter Design. In this example, the DC - 30 MHz glitch filter is selected.

## 9.1.2.2 Sampling Clock

Applications operating with low input frequencies (such as DC to 20 MHz) typically are less sensitive to performance degradation due to clock jitter. The internal ADC aperture jitter improves with faster rise and fall times (i.e. square wave vs sine wave). Table 9-4 provides an overview of the estimated SNR performance of the ADC356x based on different amounts of jitter of the external clock source. The SNR is estimated based on ADC356x thermal noise of 84.5dBFS and input signal at -1dBFS.

Table 9-4. ADC SNR performance across vs input frequency for different amounts of external clock jitter

| INPUT FREQUENCY | T <sub>J,EXT</sub> = 100 fs | T <sub>J,EXT</sub> = 250 fs | $T_{J,EXT}$ = 500 fs | T <sub>J,EXT</sub> = 1 ps |
|-----------------|-----------------------------|-----------------------------|----------------------|---------------------------|
| 5 MHz           | 82.0                        | 81.9                        | 81.8                 | 81.5                      |
| 10 MHz          | 81.9                        | 81.8                        | 81.4                 | 80.2                      |
| 20 MHz          | 81.6                        | 81.2                        | 80.1                 | 77.2                      |

Termination of the clock input should be considered for long clock traces.

#### 9.1.2.3 Voltage Reference

The ADC356x is configured to internal reference operation by applying 0.6 V to the REFBUF pin.

## 9.1.3 Application Curves

The following FFT plots show the performance of THS4541 driving the ADC3563 operated at 65 MSPS with a full-scale input at -1 dBFS and input frequencies of 5, 10 and 20 MHz.

## 9.2 Initialization Set Up

After power-up, the internal registers must be initialized to their default values through a hardware reset by applying a high pulse on the RESET pin, as shown in Figure 9-6.

- 1. Apply AVDD and IOVDD (no specific sequence required). After AVDD is applied the internal bandgap reference will power up and settle out in ~ 2ms.
- 2. Configure REFBUF pin (pull high or low even if configured via SPI later on) and apply the sampling clock.
- 3. Apply hardware reset. After hardware reset is released, the default registers are loaded from internal fuses and the internal power up capacitor calibration is initiated. The calibration takes approximately 200000 clock cycles.
- 4. Begin programming using SPI interface.

Figure 9-6. Initialization of serial registers after power up

MIN **TYP** MAX UNIT Power-on delay: delay from power up to logic level of REFBUF pin 2  $t_1$ ms Delay from REFBUF pin logic level to RESET rising edge 100  $t_2$ ns 1 RESET pulse width  $t_3$ Delay from RESET disable to SEN active ~ 200000 clock cycles

Table 9-5. Power-up timing

#### 9.2.1 Register Initialization During Operation

If required, the serial interface registers can be cleared and reset to default settings during operation either:

- through a hardware reset or
- by applying a software reset. When using the serial interface, set the RESET bit (D0 in register address 0x00) high. This setting initializes the internal registers to the default values and then self-resets the RESET bit low. In this case, the RESET pin is kept low.

After hardware or software reset the wait time is also  $\sim$  200000 clock cycles before the SPI registers can be programmed.

## 9.3 Power Supply Recommendations

The ADC356x requires two different power-supplies. The AVDD rail provides power for the internal analog circuits and the ADC itself while the IOVDD rail powers the digital interface and the internal digital circuits like decimation filter or output interface mapper. Power sequencing is not required.

The AVDD power supply must be low noise in order to achieve data sheet performance. In applications operating near DC, the 1/f noise contribution of the power supply needs to be considered as well. The ADC is designed for very good PSRR which aides with the power supply filter design.

Figure 9-7. Power supply rejection ratio (PSRR) vs frequency

There are two recommended power-supply architectures:

- 1. 1. Step down using high-efficiency switching converters, followed by a second stage of regulation using a low noise LDO to provide switching noise reduction and improved voltage accuracy.
- 2. Directly step down the final ADC supply voltage using high-efficiency switching converters. This approach provides the best efficiency, but care must be taken to ensure switching noise is minimized to prevent degraded ADC performance.

TI WEBENCH® Power Designer can be used to select and design the individual power-supply elements needed: see the WEBENCH® Power Designer

Recommended switching regulators for the first stage include the TPS62821, and similar devices.

Recommended low dropout (LDO) linear regulators include the TPS7A4701, TPS7A90, LP5901, and similar devices.

For the switch regulator only approach, the ripple filter must be designed with a notch frequency that aligns with the switching ripple frequency of the DC/DC converter. Note the switching frequency reported from WEBENCH® and design the EMI filter and capacitor combination to have the notch frequency centered as needed. Figure 9-8 and Figure 9-9 illustrate the two approaches.

AVDD and IOVDD supply voltages should not be shared in order to prevent digital switching noise from coupling into the analog signal chain.

Figure 9-8. Example: LDO Linear Regulator Approach

Figure 9-9. Example Switcher-Only Approach

# 9.4 Layout

# 9.4.1 Layout Guidelines

There are several critical signals which require specific care during board design:

- 1. Analog input and clock signals
  - Traces should be as short as possible and vias should be avoided where possible to minimize impedance discontinuities.
  - Traces should be routed using loosely coupled 100-Ω differential traces.
  - Differential trace lengths should be matched as close as possible to minimize phase imbalance and HD2 degradation.
- 2. Digital output interface
  - Traces should be routed using tightly coupled 100-Ω differential traces.
- 3. Voltage reference
  - The bypass capacitor should be placed as close to the device pins as possible and connected between VREF and REFGND – on top layer avoiding vias.
  - Depending on configuration an additional bypass capacitor between REFBUF and REFGND may be recommended and should also be placed as close to pins as possible on top layer.
- 4. Power and ground connections
  - Provide low resistance connection paths to all power and ground pins.
  - · Use power and ground planes instead of traces.
  - Avoid narrow, isolated paths which increase the connection resistance.
  - Use a signal/ground/power circuit board stackup to maximize coupling between the ground and power plane.

# 9.4.2 Layout Example

The following screen shot shows the top layer of the ADC356x/368x EVM.

- Signal and clock inputs are routed as differential signals on the top layer avoiding vias.
- SLVDS output interface lanes are routed differential and length matched
- · Bypass caps are close to the VREF pin on the top layer avoiding vias.

Figure 9-10. Layout example: top layer of ADC356x/368x EVM

# 10.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

<sup>(1)</sup> Status: For more details on status, see our product life cycle.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

<sup>(2)</sup> Material type: When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

<sup>(3)</sup> RoHS values: Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

<sup>(4)</sup> Lead finish/Ball material: Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

<sup>(5)</sup> MSL rating/Peak reflow: The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

<sup>(6)</sup> Part marking: There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

PLASTIC QUAD FLATPACK - NO LEAD

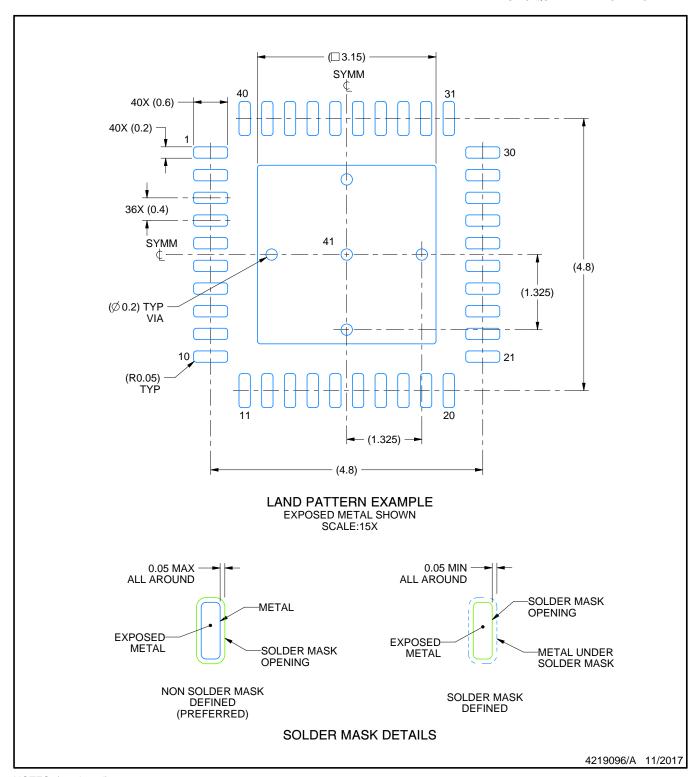

#### NOTES:

- 1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
  2. This drawing is subject to change without notice.
- 3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.

PLASTIC QUAD FLATPACK - NO LEAD

NOTES: (continued)

- 4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/slua271).
- 5. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.

PLASTIC QUAD FLATPACK - NO LEAD

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
