

ADS7042 Ultra-Low Power, Ultra-Small Size, 12-Bit, 1-MSPS, SAR ADC

1 Features

- Industry's First SAR ADC with Nanowatt Power Consumption:
 - 234 μ W at 1 MSPS with 1.8-V AVDD
 - 690 μ W at 1 MSPS with 3-V AVDD
 - 69 μ W at 100 kSPS with 3-V AVDD
 - Less than 1 μ W at 1 kSPS with 3-V AVDD
- Industry's Smallest SAR ADC:
 - X2QFN-8 Package with 2.25-mm² Footprint
- 1-MSPS Throughput with Zero Data Latency
- Wide Operating Range:
 - AVDD: 1.65 V to 3.6 V
 - DVDD: 1.65 V to 3.6 V (Independent of AVDD)
 - Temperature Range: –40°C to 125°C
- Excellent Performance:
 - 12-Bit Resolution with NMC
 - ± 1 -LSB (Max) DNL and INL
 - 70-dB SNR with 3-V AVDD
 - 80-dB THD with 3-V AVDD
- Unipolar Input Range: 0 V to AVDD
- Integrated Offset Calibration
- SPI™-Compatible Serial Interface: 16 MHz
- JESD8-7A Compliant Digital I/O

2 Applications

- Low-Power Data Acquisition
- Battery-Powered Handheld Equipment
- Level Sensors
- Ultrasonic Flow Meters
- Motor Control
- Wearable Fitness
- Portable Medical Equipment
- Hard Drives
- Glucose Meters

3 Description

The ADS7042 is a 12-bit, 1-MSPS, analog-to-digital converter (ADC). The device supports a wide analog input voltage range (1.65 V to 3.6 V) and includes a capacitor-based, successive-approximation register (SAR) ADC with an inherent sample-and-hold circuit. The SPI-compatible serial interface is controlled by the $\overline{\text{CS}}$ and $\overline{\text{SCLK}}$ signals. The input signal is sampled with the $\overline{\text{CS}}$ falling edge and SCLK is used for conversion and serial data output. The device supports a wide digital supply range (1.65 V to 3.6 V), enabling direct interface to a variety of host controllers. The ADS7042 complies with the JESD8-7A standard for a normal DVDD range (1.65 V to 1.95 V).

The ADS7042 is available in 8-pin, miniature, leaded, and X2QFN packages and is specified for operation from –40°C to 125°C. Miniature form-factor and extremely low-power consumption make this device suitable for space-constrained, battery-powered applications.

Device Information⁽¹⁾

PART NAME	PACKAGE	BODY SIZE (NOM)
ADS7042	X2QFN (8)	1.50 mm × 1.50 mm
	VSSOP (8)	2.30 mm × 2.00 mm

(1) For all available packages, see the orderable addendum at the end of the datasheet.

Typical Application

NOTE: The ADS7042 is smaller than a 0805 (2012 metric) SMD component.

4 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision B (February 2015) to Revision C	Page
• Added <i>Companion Products</i> and <i>Device Comparison</i> sections	4
• Updated Figure 1	10
• Changed <i>Serial Interface</i> section: changed last half of first paragraph, changed Figure 34	21
• Changed Figure 37	24
• Added <i>Community Resources</i> section	35

Changes from Revision A (August 2014) to Revision B	Page
• Added TI Design.....	1
• Changed <i>Wide Operating Range</i> Features bullet: changed the value of AVDD from 1.8 V to 1.65 V	1
• Changed the wide analog input voltage range value to 1.65 V in first paragraph of <i>Description</i> section.....	1
• Changed <i>ESD Ratings</i> table to latest standards	7
• Changed AVDD parameter minimum specification in <i>Recommended Operating Conditions</i> table to 1.65 V	7
• Changed E _O parameter uncalibrated test conditions in <i>Electrical Characteristics</i> table	8
• Changed Maximum throughput rate parameter test conditions in <i>Electrical Characteristics</i> table	8
• Changed AVDD parameter minimum specification in <i>Electrical Characteristics</i> table.....	9
• Changed conditions for <i>Timing Characteristics</i> table: changed range of AVDD and added C _{LOAD} condition.....	10
• Changed t _{D_CKDO} parameter in <i>Timing Characteristics</i> table	10
• Added f _{SCLK} minimum specification to <i>Timing Characteristics</i> table	10
• Changed titles of Figure 26 to Figure 29	14
• Changed <i>Reference</i> sub-section in <i>Feature Description</i> section	18
• Changed range of second f _{CLK-CAL} parameter description in Table 2	23
• Changed range of second f _{CLK-CAL} parameter description in Table 3	24

-
- Changed *Reference Circuit* section in *Application Information* [27](#)
 - Added last two sentences to *AVDD and DVDD Supply Recommendations* section [33](#)
-

Changes from Original (June 2014) to Revision A

5 Companion Products

PART NUMBER	NAME
ADS1298	8-Channel, 24-Bit Analog-To-Digital Converter With Integrated ECG Front End
OPA835	Ultra Low Power, Rail to Rail Out, Negative Rail In, VFB Amplifier
OPA314	3MHz, Low-Power, Low-Noise, RRI/O, 1.8V CMOS Operational Amplifier
ADS1294	4-Channel, 24-Bit Analog-To-Digital Converter With Integrated ECG Front End
ADS1298R	8-Channel, 24-Bit Analog-To-Digital Converter w/Integrated Respiration Impedance and ECG Front End

6 Device Comparison

DEVICE	RESOLUTION (Bits)	ANALOG INPUT	THROUGHPUT (MSPS)
ADS7040	8	Single-ended	1
ADS7041	10	Single-ended	1
ADS7042	12	Single-ended	1
ADS7043	12	Pseudo-differential	1
ADS7044	12	Fully differential	1

7 Pin Configuration and Functions

Pin Functions

NAME	PIN NO.		I/O	DESCRIPTION
	RUG	DCU		
AINM	8	5	Analog input	Analog signal input, negative
AINP	7	6	Analog input	Analog signal input, positive
AVDD	6	7	Supply	Analog power-supply input, also provides the reference voltage to the ADC
$\overline{\text{CS}}$	1	4	Digital input	Chip-select signal, active low
DVDD	4	1	Supply	Digital I/O supply voltage
GND	5	8	Supply	Ground for power supply, all analog and digital signals are referred to this pin
SCLK	3	2	Digital input	Serial clock
SDO	2	3	Digital output	Serial data out

8 Specifications

8.1 Absolute Maximum Ratings⁽¹⁾

	MIN	MAX	UNIT
AVDD to GND	–0.3	3.9	V
DVDD to GND	–0.3	3.9	V
AINP to GND	–0.3	AVDD + 0.3	V
AINM to GND	–0.3	0.3	V
Digital input voltage to GND	–0.3	DVDD + 0.3	V
Storage temperature, T _{stg}	–60	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

8.2 ESD Ratings

		VALUE	UNIT
V _(ESD) Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
	Charged device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±1000	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

8.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

	MIN	MAX	UNIT
AVDD Analog supply voltage range	1.65	3.6	V
DVDD Digital supply voltage range	1.65	3.6	V
T _A Operating free-air temperature	–40	125	°C

8.4 Thermal Information

THERMAL METRIC ⁽¹⁾		ADS7042		UNIT
		RUG (X2QFN)	DCU (VSSOP)	
		8 PINS	8 PINS	
R _{θJA}	Junction-to-ambient thermal resistance	177.5	235.8	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	51.5	79.8	°C/W
R _{θJB}	Junction-to-board thermal resistance	76.7	117.6	°C/W
ψ _{JT}	Junction-to-top characterization parameter	1.0	8.9	°C/W
ψ _{JB}	Junction-to-board characterization parameter	76.7	116.5	°C/W
R _{θJC(bot)}	Junction-to-case (bottom) thermal resistance	N/A	N/A	°C/W

- (1) For more information about traditional and new thermal metrics, see the *IC Package Thermal Metrics* application report, [SPRA953](#).

8.5 Electrical Characteristics

At $T_A = -40^{\circ}\text{C}$ to 125°C , $\text{AVDD} = 3\text{ V}$, $\text{DVDD} = 1.65\text{ V}$ to 3.6 V , $f_{\text{SAMPLE}} = 1\text{ MSPS}$, and $V_{\text{AINM}} = 0\text{ V}$, unless otherwise noted.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
ANALOG INPUT

9 Parameter Measurement Information

9.1 Digital Voltage Levels

The device complies with the JESD8-7A standard for DVDD from 1.65 V to 1.95 V. [Figure 30](#) shows voltage levels for the digital input and output pins.

Figure 30. Digital Voltage Levels as per the JESD8-7A Standard

10 Detailed Description

10.1 Overview

The ADS7042 is an ultralow-power, ultra-small analog-to-digital converter (ADC) that supports a wide analog input range. The analog input range for the device is defined by the AVDD supply voltage. The device samples the input voltage across the AINP and AINM pins on the $\overline{CS}$ falling edge and starts the conversion. The clock provided on the SCLK pin is used for conversion and data transfer. During conversions, both the AINP and AINM pins are disconnected from the sampling circuit. After the conversion completes, the sampling capacitors are reconnected across the AINP and AINM pins and the ADS7042 enters acquisition phase.

The device has an internal offset calibration. The offset calibration can be initiated by the user either on power-up or during normal operation; see the [Offset Calibration](#) section for more details.

The device also provides a simple serial interface to the host controller and operates over a wide range of digital power supplies. The ADS7042 requires only a 16-MHz SCLK for supporting a throughput of 1 MSPS. The digital interface also complies with the JESD8-7A (normal range) standard. The [Functional Block Diagram](#) section provides a block diagram of the device.

10.2 Functional Block Diagram

10.3 Feature Description

10.3.1 Reference

The device uses the analog supply voltage (AVDD) as a reference, as shown in [Figure 31](#). TI recommends decoupling the AVDD pin with a 1- μ F, low equivalent series resistance (ESR) ceramic capacitor. The minimum capacitor value required for AVDD is 200 nF. The AVDD pin functions as a switched capacitor load to the source powering AVDD. The decoupling capacitor provides the instantaneous charge required by the internal circuit and helps in maintaining a stable dc voltage on the AVDD pin. TI recommends powering the AVDD pin with a low output impedance and low-noise regulator (such as the [TPS79101](#)).

Figure 31. Reference for the Device

Feature Description (continued)

10.3.2 Analog Input

The device supports single-ended analog inputs. The ADC samples the difference between AINP and AINM and converts for this voltage. The device is capable of accepting a signal from –100 mV to 100 mV on the AINM input and is useful in systems where the sensor or signal-conditioning block is far from the ADC. In such a scenario, there can be a difference between the ground potential of the sensor or signal conditioner and the ADC ground. In such cases, use separate wires to connect the ground of the sensor or signal conditioner to the AINM pin. The AINP input is capable of accepting signals from 0 V to AVDD. Figure 32 represents the equivalent analog input circuits for the sampling stage. The device has a low-pass filter followed by the sampling switch and sampling capacitor. The sampling switch is represented by an R_s (typically 50 Ω) resistor in series with an ideal switch and C_s (typically 15 pF) is the sampling capacitor. The ESD diodes are connected from both analog inputs to AVDD and ground.

Figure 32. Equivalent Input Circuit for the Sampling Stage

The analog input full-scale range (FSR) is equal to the reference voltage of the ADC. The reference voltage for the device is equal to the analog supply voltage (AVDD). Thus, the device FSR can be determined by Equation 1:

$$\text{FSR} = V_{\text{REF}} = \text{AVDD} \quad (1)$$

10.3.3 ADC Transfer Function

The device output is in straight binary format. The device resolution for a single-ended input can be computed by Equation 2:

$$1 \text{ LSB} = V_{\text{REF}} / 2^N$$

where:

- $V_{\text{REF}} = \text{AVDD}$ and
- $N = 12$

(2)

Feature Description (continued)

Figure 33 and Table 1 show the ideal transfer characteristics for the device.

Figure 33. Ideal Transfer Characteristics

Table 1. Transfer Characteristics

INPUT VOLTAGE (AINP – AINM)	CODE	DESCRIPTION	IDEAL OUTPUT CODE
$\leq 1 \text{ LSB}$	NFSC	Negative full-scale code	000
1 LSB to 2 LSBs	NFSC + 1	—	001
$(V_{REF}/2)$ to $(V_{REF}/2) + 1 \text{ LSB}$	MC	Mid code	800
$(V_{REF}/2) + 1 \text{ LSB}$ to $(V_{REF}/2) + 2 \text{ LSBs}$	MC + 1	—	801
$\geq V_{REF} - 1 \text{ LSB}$	PFSC	Positive full-scale code	FFF

10.3.4 Serial Interface

The device supports a simple, SPI-compatible interface to the external host. The $\overline{\text{CS}}$ signal defines one conversion and serial transfer frame. A frame starts with a $\overline{\text{CS}}$ falling edge and ends with a $\overline{\text{CS}}$ rising edge. The SDO pin outputs the ADC conversion results. Figure 34 shows a detailed timing diagram for the serial interface. A minimum delay of $t_{\text{SU_CSCK}}$ must elapse between the $\overline{\text{CS}}$ falling edge and the first SCLK falling edge. The device uses the clock provided on the SCLK pin for conversion and data transfer. The conversion result is available on the SDO pin with the first two bits set to 0, followed by 12 bits of the conversion result. The first zero is launched on the SDO pin on the $\overline{\text{CS}}$ falling edge. Subsequent bits (starting with another 0 followed by the conversion result) are launched on the SDO pin on subsequent SCLK falling edges. The SDO output remains low after 14 SCLKs. A $\overline{\text{CS}}$ rising edge ends the frame and brings the serial data bus to 3-state. For acquisition of the next sample, a minimum time of t_{ACQ} must be provided after the conversion of the current sample is completed. For details on timing specifications, see the [Timing Characteristics](#) table.

The device initiates an offset calibration on the first $\overline{\text{CS}}$ falling edge after power-up and the SDO output remains low during the first serial transfer frame after power-up. For further details, refer to the [Offset Calibration](#) section.

Figure 34. Serial Interface Timing Diagram

10.4 Device Functional Modes

10.4.1 Offset Calibration

The ADS7042 includes a feature to calibrate the device internal offset. During offset calibration, the analog input pins (AINP and AINM) are disconnected from the sampling stage. The device includes an internal offset calibration register (OCR) that stores the offset calibration result. The OCR is an internal register and cannot be accessed by the user through the serial interface. The OCR is reset to zero on power-up. Therefore, TI recommends calibrating the offset on power-up to bring the offset within the specified limits. If the operating temperature or analog supply voltage reflect a significant change, the offset can be recalibrated during normal operation. Figure 35 shows the offset calibration process.

- (1) See the [Timing Characteristics](#) section for timing specifications.
- (2) See the [Offset Calibration During Normal Operation](#) section for details.
- (3) See the [Offset Calibration on Power-Up](#) section for details.
- (4) The power recycle on the AVDD supply is required to reset the offset calibration and to bring the device to a power-up state.

Figure 35. Offset Calibration

Device Functional Modes (continued)

10.4.1.1 Offset Calibration on Power-Up

The device initiates offset calibration on the first $\overline{\text{CS}}$ falling edge after power-up and calibration completes if the $\overline{\text{CS}}$ pin remains low for at least 16 SCLK falling edges after the first $\overline{\text{CS}}$ falling edge. The SDO output remains low during calibration. The minimum acquisition time must be provided after calibration for acquiring the first sample. If the device is not provided with at least 16 SCLKs during the first serial transfer frame after power-up, the OCR is not updated. Table 2 provides the timing parameters for offset calibration on power-up.

For subsequent samples, the device adjusts the conversion results with the value stored in the OCR. The conversion result adjusted with the value stored in OCR is provided by the device on the SDO output. Figure 36 shows the timing diagram for offset calibration on power-up.

Table 2. Offset Calibration on Power-Up

		MIN	TYP	MAX	UNIT
$f_{\text{CLK-CAL}}$	SCLK frequency for calibration for 2.25 V < AVDD < 3.6 V			16	MHz
$f_{\text{CLK-CAL}}$	SCLK frequency for calibration for 1.65 V < AVDD < 2.25 V			12	MHz
$t_{\text{POWERUP-CAL}}$	Calibration time at power-up	15 t_{SCLK}			ns
t_{ACQ}	Acquisition time	200			ns
$t_{\text{PH-CS}}$	$\overline{\text{CS}}$ high time	t_{ACQ}			ns

$t_{\text{D-CKCS}}$	Delay time: last SCLK falling to $\overline{\text{CS}}$ rising	10			ns

Figure 36. Offset Calibration on Power-Up Timing Diagram

10.4.1.2 Offset Calibration During Normal Operation

Offset calibration can be done during normal device operation if at least 32 SCLK falling edges are provided in one serial transfer frame. During the first 14 SCLKs, the device converts the sample acquired on the CS falling edge and provides data on the SDO output. The device initiates the offset calibration on the 17th SCLK falling edge and calibration completes on the 32nd SCLK falling edge. The SDO output remains low after the 14th SCLK falling edge and SDO goes to 3-state after $\overline{CS}$ goes high. If the device is provided with less than 32 SCLKs during a serial transfer frame, the OCR is not updated. Table 3 provides the timing parameters for offset calibration during normal operation.

For subsequent samples, the device adjusts the conversion results with the value stored in the OCR. The conversion result adjusted with the value stored in the OCR is provided by the device on the SDO output. Figure 37 shows the timing diagram for offset calibration during normal operation.

Table 3. Offset Calibration During Normal Operation

		MIN	TYP	MAX	UNIT
$f_{CLK-CAL}$	SCLK frequency for calibration for $2.25\text{ V} < AVDD < 3.6\text{ V}$			16	MHz
$f_{CLK-CAL}$	SCLK frequency for calibration for $1.65\text{ V} < AVDD < 2.25\text{ V}$			12	MHz
t_{CAL}	Calibration time during normal operation	15 t_{SCLK}			ns
t_{ACQ}	Acquisition time	200			ns
t_{PH_CS}	$\overline{CS}$ high time	t_{ACQ}			ns
t_{SU_CSCK}	Setup time: $\overline{CS}$ falling to SCLK falling	15			ns
t_{D_CKCS}	Delay time: last SCLK falling to $\overline{CS}$ rising	10			ns

Figure 37. Offset Calibration During Normal Operation Timing Diagram

11 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

11.1 Application Information

The two primary circuits required to maximize the performance of a high-precision, successive approximation register (SAR), analog-to-digital converter (ADC) are the input driver and the reference driver circuits. This section details some general principles for designing the input driver circuit, reference driver circuit, and provides some application circuits designed for the ADS7042.

11.2 Typical Applications

11.2.1 Single-Supply DAQ with the ADS7042

Figure 38. DAQ Circuit: Single-Supply DAQ

11.2.1.1 Design Requirements

The goal of this application is to design a single-supply digital acquisition (DAQ) circuit based on the ADS7042 with SNR greater than 68 dB and THD less than –80 dB for input frequencies of 2.5 kHz at a throughput of 1 MSPS.

11.2.1.2 Detailed Design Procedure

The input driver circuit for a high-precision ADC mainly consists of two parts: a driving amplifier and an antialiasing filter. Careful design of the front-end circuit is critical to meet the linearity and noise performance of a high-precision ADC.

Typical Applications (continued)

11.2.1.2.1 Antialiasing Filter

Converting analog-to-digital signals requires sampling an input signal at a rate greater than or equal to the Nyquist rate. Any higher frequency content in the input signal beyond half the sampling frequency is digitized and folded back into the low-frequency spectrum. This process is called *aliasing*. Therefore, an external, antialiasing filter must be used to remove the harmonic content from the input signal before being sampled by the ADC. An antialiasing filter is designed as a low-pass RC filter, for which the 3-dB bandwidth is optimized for noise, response time, and throughput. For dc signals with fast transients (including multiplexed input signals), a high-bandwidth filter is designed to allow accurately settling the signal at the ADC inputs during the small acquisition time window. Figure 39 provides the equation for determining the bandwidth of the antialiasing filter.

Figure 39. Antialiasing Filter

For ac signals, the filter bandwidth must be kept low to band limit the noise fed into the ADC input, thereby increasing the signal-to-noise ratio (SNR) of the system. Besides filtering the noise from the front-end drive circuitry, the RC filter also helps attenuate the sampling charge injection from the switched-capacitor input stage of the ADC. A filter capacitor, C_{FLT} , is connected across the ADC inputs. This capacitor helps reduce the sampling charge injection and provides a charge bucket to quickly charge the internal sample-and-hold capacitors during the acquisition process. As a rule of thumb, the value of this capacitor is at least 20 times the specified value of the ADC sampling capacitance. For this device, the input sampling capacitance is equal to 15 pF. Thus, the value of C_{FLT} is greater than 300 pF. Select a COG- or NPO-type capacitor because these capacitor types have a high-Q, low-temperature coefficient, and stable electrical characteristics under varying voltages, frequency, and time.

Note that driving capacitive loads can degrade the phase margin of the input amplifiers, thus making the amplifier marginally unstable. To avoid amplifier stability issues, series isolation resistors (R_{FLT}) are used at the output of the amplifiers. A higher value of R_{FLT} is helpful from the amplifier stability perspective, but adds distortion as a result of interactions with the nonlinear input impedance of the ADC. Distortion increases with source impedance, input signal frequency, and input signal amplitude. Therefore, the selection of R_{FLT} requires balancing the stability and distortion of the design.

The input amplifier bandwidth is typically much higher than the cutoff frequency of the antialiasing filter. Thus, TI strongly recommends performing a SPICE simulation to confirm that the amplifier has more than 40° phase margin with the selected filter. Simulation is critical because even with high-bandwidth amplifiers, some amplifiers can require more bandwidth than others to drive similar filters.

Typical Applications (continued)

11.2.1.2.2 Input Amplifier Selection

Selection criteria for the input amplifiers is highly dependent on the input signal type and the performance goals of the data acquisition system. Some key amplifier specifications to consider when selecting an appropriate amplifier to drive the inputs of the ADC are:

- **Small-signal bandwidth:** Select the small-signal bandwidth of the input amplifiers to be high enough to settle the input signal in the acquisition time of the ADC. Higher bandwidth reduces the closed-loop output impedance of the amplifier, thus allowing the amplifier to more easily drive the low cutoff frequency RC filter at the ADC inputs. Higher bandwidth also minimizes the harmonic distortion at higher input frequencies. In order to maintain the overall stability of the input driver circuit, the select the amplifier bandwidth as described in [Equation 3](#).

$$GBW \geq 4 \times \frac{1}{2\pi \times R_{FLT} \times C_{FLT}}$$

where:

- GBW = unity gain bandwidth (3)
- **Noise:** Noise contribution of the front-end amplifiers must be low enough to prevent any degradation in SNR performance of the system. As a rule of thumb, to ensure that the noise performance of the data acquisition system is not limited by the front-end circuit, keep the total noise contribution from the front-end circuit below 20% of the input-referred noise of the ADC. Noise from the input driver circuit is band limited by designing a low cutoff frequency RC filter, as explained in [Equation 4](#).

$$N_G \times \sqrt{\left(\frac{V_{1/f_AMP_PP}}{6.6}\right)^2 + e_{n_RMS}^2 \times \frac{\pi}{2} \times f_{-3dB}} \leq \frac{1}{5} \times \frac{V_{REF}}{2\sqrt{2}} \times 10^{-\left(\frac{SNR(dB)}{20}\right)}$$

where:

- V_{1/f_AMP_PP} is the peak-to-peak flicker noise in $\mu VRMS$,
- e_{n_RMS} is the amplifier broadband noise,
- f_{-3dB} is the -3 -dB bandwidth of the RC filter, and
- N_G is the noise gain of the front-end circuit, which is equal to 1 in the buffer configuration. (4)
- **Settling time:** For dc signals with fast transients that are common in a multiplexed application, the input signal must settle to the desired accuracy at the inputs of the ADC during the acquisition time window. This condition is critical to maintain the overall linearity performance of the ADC. Typically, the amplifier data sheets specify the output settling performance only up to 0.1% to 0.001%, which may not be sufficient for the desired accuracy. Therefore, always verify the settling behavior of the input driver with TINA™-SPICE simulations before selecting the amplifier.

The OPA314 is selected for this application for its rail-to-rail input and output swing, low-noise (14 nV/ $\sqrt{Hz}$), and low-power (150 μA) performance to support a single-supply data acquisition circuit.

11.2.1.2.3 Reference Circuit

The analog supply voltage of the device is also used as a voltage reference for conversion. TI recommends decoupling the AVDD pin with a 1- μF , low-ESR ceramic capacitor. The minimum capacitor value required for AVDD is 200 nF.

Typical Applications (continued)

11.2.1.3 Application Curve

Figure 40 shows the FFT plot for the ADS7042 with a 2.5-kHz input frequency used for the circuit in Figure 38.

SNR = 69 dB

THD = -80 dB

SINAD = 68.6 dB

Number of samples = 32768

Figure 40. Test Results for the ADS7042 and OPA314 for a 2.5-kHz Input

Typical Applications (continued)

11.2.2 DAQ Circuit with the ADS7042 for Maximum SINAD

Figure 41. ADS7042 DAQ Circuit: Maximum SINAD for Input Frequencies up to 250 kHz

11.2.2.1 Design Requirements

The goal of this application is to design a data acquisition circuit based on the ADS7042 with SINAD greater than 69.5 dB for input frequencies up to 250 kHz.

11.2.2.2 Detailed Design Procedure

To achieve a SINAD of 69.5 dB, the operational amplifier must have high bandwidth in order to settle the input signal within the acquisition time of the ADC. The operational amplifier must have low noise to keep the total system noise below 20% of the input-referred noise of the ADC. For the application circuit shown in [Figure 41](#), the [OPA835](#) is selected for its high bandwidth (56 MHz) and low noise (9.3 nV/√Hz).

For a step-by-step design procedure, circuit schematics, bill of materials, PCB files, simulation results, and test results, refer to [TI Precision Design TIPD168, Three 12-Bit Data Acquisition Reference Designs Optimized for Low Power and Ultra-Small Form Factor \(TIDU390\)](#).

11.2.2.3 Application Curves

Figure 42 shows the FFT plot for the ADS7042 with a 2-kHz input frequency used for the circuit in Figure 41. Figure 43 shows the FFT plot for the ADS7042 with a 250-kHz input frequency used for the circuit in Figure 41.

11.2.3 12-Bit, 10-kSPS DAQ Circuit Optimized for DC Sensor Measurements

Figure 44. Interfacing the Device Directly with Sensors

In applications where the input is very slow moving and the overall system ENOB is not a critical parameter, a DAQ circuit can be designed without the input driver for the ADC. This type of a use case is of particular interest for applications in which the primary goal is to achieve the absolute lowest power possible. Typical applications that fall into this category are low-power sensor applications (such as temperature, pressure, humidity, gas, and chemical).

11.2.3.1 Design Requirements

For this design example, use the parameters listed in [Table 4](#) as the input parameters.

Table 4. Design Parameters

DESIGN PARAMETER	GOAL VALUE
Throughput	10 kSPS
SNR at 100 Hz	70 dB
THD at 100 Hz	75dB
SINAD at 100 Hz	69 dB
ENOB	11
Power	10 μ W

11.2.3.2 Detailed Design Procedure

The ADS7042 can be directly interfaced with sensors at lower throughputs without the need of an amplifier buffer. The analog input source drive must be capable of driving the switched capacitor load of a SAR ADC and settling the analog input signal within the acquisition time of the SAR ADC. However, the output impedance of the sensor must be taken into account when interfacing a SAR ADC directly with sensors. Drive the analog input of the SAR ADC with a low impedance source. The input signal requires more acquisition time to settle to the desired accuracy because of the higher output impedance of the sensor. The simplified circuit for a sensor as a voltage source with output impedance (R_{OUT}) is shown in [Figure 44](#).

The acquisition time of a SAR ADC (such as the ADS7042) can be increased by reducing throughput in the following ways:

1. Reducing the SCLK frequency to reduce the throughput, or
2. Keeping the SCLK fixed at the highest permissible value (that is, 16 MHz for the device) and increasing the CS high time.

Table 5 lists the acquisition time for the above two cases for a throughput of 100 kSPS. Clearly, case 2 provides more acquisition time for the input signal to settle.

Table 5. Acquisition Time with Different SCLK Frequencies

CASE	SCLK	t _{cycle}	CONVERSION TIME (= 12.5 × t _{SCLK} + t _{SU_CSCk})	ACQUISITION TIME (= t _{cycle} – t _{conv})
1	1.6 MHz	10 μs	7.8125 μs	2.1875 μs
2	16 MHz	10 μs	0.78125 μs	9.21875 μs

For a step-by-step design procedure, circuit schematics, bill of materials, PCB files, simulation results, and test results, refer to [TI Precision Design TIPD168, Three 12-Bit Data Acquisition Reference Designs Optimized for Low Power and Ultra-Small Form Factor \(TIDU390\)](#).

11.2.3.3 Application Curve

When the output impedance of the sensor increases, the time required for the input signal to settle increases and the performance of the SAR ADC starts degrading if the input signal does not settle within the acquisition time of the ADC. The performance of the SAR ADC can be improved by reducing the throughput to provide enough time for the input signal to settle. Figure 45 provides the results for ENOB achieved from the ADS7042 for case 2 at different throughputs with different input impedances at the device input.

Figure 45. ENOB (Effective Number of Bits) Achieved from the ADS7042 at Different Throughputs

Table 6 shows the results and performance summary for this 12-bit, 10-kSPS DAQ circuit application.

Table 6. Results and Performance Summary for 12-Bit, 10-kSPS DAQ Circuit for DC Sensor Measurements

DESIGN PARAMETER	GOAL VALUE	ACHIEVED RESULT
Throughput	10 kSPS	10 kSPS
SNR at 100 Hz	70 dB	70.6 dB
THD at 100 Hz	75dB	83.5 dB
SINAD at 100 Hz	69dB	70.4 dB
ENOB	11	11.4
Power	10 μW	7 μW

12 Power-Supply Recommendations

12.1 AVDD and DVDD Supply Recommendations

The ADS7042 has two separate power supplies: AVDD and DVDD. The device operates on AVDD; DVDD is used for the interface circuits. AVDD and DVDD can be independently set to any value within the permissible ranges. The AVDD supply also defines the full-scale input range of the device. Always set the AVDD supply to be greater than or equal to the maximum input signal to avoid saturation of codes. Decouple the AVDD and DVDD pins individually with 1-μF ceramic decoupling capacitors, as shown in Figure 46. The minimum capacitor value required for AVDD and DVDD is 200 nF and 20 nF, respectively. If both supplies are powered from the same source, a minimum capacitor value of 220 nF is required for decoupling.

Figure 46. Power-Supply Decoupling

12.2 Estimating Digital Power Consumption

The current consumption from the DVDD supply depends on the DVDD voltage, load capacitance on the SDO line, and the output code. The load capacitance on the SDO line is charged by the current from the SDO pin on every rising edge of the data output and is discharged on every falling edge of the data output. The current consumed by the device from the DVDD supply can be calculated by Equation 5:

$$I_{DVDD} = C \times V \times f$$

where:

- C = Load capacitance on the SDO line,
- V = DVDD supply voltage, and
- f = Number of transitions on the SDO output. (5)

The number of transitions on the SDO output depends on the output code, and thus changes with the analog input. The maximum value of f occurs when data output on the SDO change on every SCLK. SDO changing on every SCLK results in an output code of AAAh or 555h. For an output code of AAAh or 555h at a 1-MSPS throughput, the frequency of transitions on the SDO output is 6MHz.

For the current consumption to remain at the lowest possible value, keep the DVDD supply at the lowest permissible value and keep the capacitance on the SDO line as low as possible.

12.3 Optimizing Power Consumed by the Device

- Keep the analog supply voltage (AVDD) as close as possible to the analog input voltage. Set AVDD to be greater than or equal to the analog input voltage of the device.
- Keep the digital supply voltage (DVDD) at the lowest permissible value.
- Reduce the load capacitance on the SDO output.
- Run the device at the optimum throughput. Power consumption reduces with throughput.

13 Layout

13.1 Layout Guidelines

Figure 47 shows a board layout example for the ADS7042. Use a ground plane underneath the device and partition the PCB into analog and digital sections. Avoid crossing digital lines with the analog signal path and keep the analog input signals and the reference input signals away from noise sources. In Figure 47, the analog input and reference signals are routed on the top and left side of the device and the digital connections are routed on the bottom and right side of the device.

The power sources to the device must be clean and well-bypassed. Use 1- μ F ceramic bypass capacitors in close proximity to the analog (AVDD) and digital (DVDD) power-supply pins. Avoid placing vias between the AVDD and DVDD pins and the bypass capacitors. Connect all ground pins to the ground plane using short, low-impedance paths. The AVDD supply voltage for the ADS7042 also functions as a reference for the device. Place the decoupling capacitor (C_{REF}) for AVDD close to the device AVDD and GND pins and connect C_{REF} to the device pins with thick copper tracks, as shown in Figure 47.

The fly-wheel RC filters are placed close to the device. Among ceramic surface-mount capacitors, COG (NPO) ceramic capacitors provide the best capacitance precision. The type of dielectric used in COG (NPO) ceramic capacitors provides the most stable electrical properties over voltage, frequency, and temperature changes.

14.4 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "-" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
