

LM15851 SLAS990E - JANUARY 2014-REVISED OCTOBER 2017

LM15851 Ultra-Wideband RF Sampling Subsystem

Features

- Excellent Noise and Linearity up to and beyond $F_{IN} = 3 GHz$
- Configurable DDC
- Decimation Factors from 4 to 32 (Complex Baseband Out)
- Usable Output Bandwidth of 800 MHz at 4x Decimation and 4000 MSPS
- Usable Output Bandwidth of 100 MHz at 32x Decimation and 4000 MSPS
- Low Pin-Count JESD204B Subclass 1 Interface
- Automatically Optimized Output Lane Count
- **Embedded Low Latency Signal Range Indication**
- Low Power Consumption

Key Specifications:

Max Sampling Rate: 4000 MSPS

Min Sampling Rate: 1000 MSPS

- DDC Output Word Size: 15-Bit Complex (30 bits total)
- IMD3: -64 dBc (F_{IN} = 2140 MHz ± 30 MHz at -13 dBFS)
- FPBW (-3 dB): 3.2 GHz
- Supply Voltages: 1.9 V and 1.2 V
- Power Consumption
 - Decimate by 10 (4000 MSPS): 2 W
 - Power Down Mode: <50 mW

2 Applications

- Wireless Infrastructure
- RF-Sampling Software Defined Radio
- Wideband Microwave Backhaul
- DOCSIS / Cable Infrastructure

3 Description

The LM15851 device is a wideband sampling and digital tuning device. Texas Instruments' giga-sample analog-to-digital converter (ADC) technology enables a large block of frequency spectrum to be sampled directly at RF. An integrated DDC (Digital Down Converter) provides digital filtering and downconversion. The selected frequency block is made available on a JESD204B serial interface. Data is output as baseband 15-bit complex information for ease of downstream processing. Based on the digital down-converter (DDC) decimation and link output rate settings, this data is output on 1 to 5 lanes of the serial interface.

The LM15851 device is available in a 68-pin VQFN package. The device operates over the Industrial $(-40^{\circ}\text{C} \le \text{T}_{\text{A}} \le 85^{\circ}\text{C})$ ambient temperature range.

Device Information⁽¹⁾

PART NUMBER	PACKAGE	BODY SIZE (NOM)
LM15851	VQFN (68)	10.00 mm × 10.00 mm

(1) For all available packages, see the orderable addendum at the end of the datasheet.

Decimate by 16 — Spectral Response $f_S = 4 \text{ GHz}, F_{IN} = 1897 \text{ MHz at } -1 \text{ dBFS}, f_{(NCO x)} = 1827 \text{ MHz}$

4 Revision History

C	nanges from Revision D (July 2015) to Revision E		
•	Changed reset value of address 0x006 from 0x03 to 0x13 in Memory Map table	48	
•	Changed reset value of address 0x006 from 0x03 to 0x13 in Standard SPI-3.0 Registers table	5	
•	Changed 0x03 to 0x13 in reset value and description of bits 7-0 and changed 0000 0011 to 0001 0011 in Chip Version Register section	52	
_	hanges from Revision C (Sentember 2014) to Revision D	Dogg	

CI	hanges from Revision C (September 2014) to Revision D	Page
•	Deleted references to time stamp including pin names (TMST+, TMST-).	
•	Added additional voltage difference parameters to the Absolute Maximum Ratings table	!
•	Added junction temperature to the Absolute Maximum Ratings table	!
•	Added common mode voltage parameter to the Recommended Operating Conditions table. Changed CLK to SYSREF, and ~SYNC	10
•	Deleted the Differential Analog Input Connection image in The Analog Inputs section	2
•	Added note about offset adjust in Background Calibration Mode to the Offset Adjust section and I/O offset register tables	
•	Added the Calibration Cycle Timing for Different Calibration Modes and Options table in the Timing Calibration Mode section	4
•	Changed 0x004-0x005 to RESERVED in the Standard SPI-3.0 Registers summary table	5
•	Changed the name of bit 0 in the Clock Generator Control 0 Register from DC_LVPECL_TS_EN to DC_LVPECL_SYNC_en	50

•	Changed the device status from Product Preview to Production Data

Product Folder Links: LM15851

Changes from Revision B (February 2014) to Revision C

Page

Cł	nanges from Original (January 2014) to Revision A	Page
•	Moved the Key Specifications list into the Features list	1
•	Replaced the Other Spurs: -81 dBFS bullet item with FPBW (-3 dB): 3.3 GHz bullet item in the Key Specifications Features list	1
•	Deleted the <i>under development</i> statement from the <i>Description</i>	1
•	Added Table of Contents (Description (continued) section now follows the Revision History)	1
•	Added Device Information table	1
•	Moved the pin configuration illustration and pin functions table into a new <i>Pin and Configurations</i> section. Changed Symbol column name to NAME column name	
•	Added the <i>Device and Documentation Support</i> section which now contains the trademarks and electrostatic discharge caution	82
•	Added the Mechanical, Packaging, and Orderable Information section	82

5 Pin Configuration and Functions

DNC = Make no external connection

Pin Functions

PIN				
NAME	NO.	EQUIVALENT CIRCUIT	TYPE	DESCRIPTION
ANALOG	+			
RBIAS+	1	VA19		
RBIAS-	2	V _{BIAS}	I/O	External Bias Resistor Connections External bias resistor terminals. A 3.3 k Ω ($\pm 0.1\%$) resistor should be connected between RBIAS+ and RBIAS—. The RBIAS resistor is used as a reference for internal circuits which affect the linearity of the converter. The value and precision of this resistor should not be compromised. These pins must be isolated from all other signals and grounds.
TDIODE-	63	Tdiode+ O		
TDIODE+	64	Tdiode-	Passive	Temperature Diode These pins are the positive (anode) and negative (cathode) diode connections for die temperature measurements. Leave these pins unconnected if they are not used. See the Built-In Temperature Monitor Diode section for more details.
VBG	68	VA19	0	Bandgap Output Voltage This pin is capable of sourcing or sinking 100 μA and can drive a load up to 80 pF. Leave this pin unconnected if it is not used in the application. See the <i>The Reference Voltage</i> section for more details.
VCMO	3	VCM	0	Common Mode Voltage The voltage at this pin must be the common-mode input voltage at the VIN+ and VIN- pins when DC coupling is used. This pin is capable of sourcing or sinking 100 μ A and can drive a load up to 80 pF. Leave this pin unconnected if it is not used in the application.
VIN+	8	VA19		
VIN-	9	VIN+ To T&H+ SO Ω 20 kΩ	ı	Signal Input The differential full-scale input range is determined by the full-scale voltage adjust register. An internal peaking inductor (L _{PEAK}) of 5 nH is included for parasitic compensation.

Pin Functions (continued)

		-		ions (continued)
PIN	EQUIVALENT CIRCUIT		TYPE	DESCRIPTION
NAME	NO.			
DATA				
DS0-	32			
DS0+	33	VD12 VA19		
DS1-	35			
DS1+	36	50 Ω Τ Τ +		Data
DS2-	38	- W - O	0	CML These pins are the high-speed serialized-data outputs with user-configurable pre-emphasis. These outputs must always be terminated with a $100-\Omega$ differential
DS2+	39	50 Ω		resistor at the receiver.
DS3-	41	† † †		
DS3+	42	GND		
DS4-	44	GND		
DS4+	45			
GROUND, RESE	RVED, D	NC		
DNC	67		_	Do Not Connect Do not connect DNC to any circuitry, power, or ground signals.
RSV	66	VA19	_	Reserved Connect to Ground or Leave Unconnected: This reserved pin is a logic input for possible future device versions. It is recommended to connect this pin to ground. Floating this pin is also permissible.
RSV2	61	GND	_	Reserved Connect to Ground Connect this reserved input pin to ground for proper operation.
Thermal Pad			_	Ground (GND) The exposed pad on the bottom of the package is the ground return for all supplies. This pad must be connected with multiple vias to the printed circuit board (PCB) ground planes to ensure proper electrical and thermal performance. The exposed center pad on the bottom of the package must be thermally and electrically connected (soldered) to a ground plane to ensure rated performance.
LVCMOS				
NCO_0	47, 48	VA19		
NCO_1	50, 51	50 Ω		NCO ConfigSelect
NCO_2	53, 54	SO Q SND	I	These three pin pairs allow the host device to select the specific NCO frequency or phase accumulator that is active. Each pair must be connected together and driven with a common 1.8-V LVCMOS signal. Connect these inputs to GND if they are not used in the application.
OR_T0	25	VA19		
OR_T1	26	GND	0	Over-Range Over-range detection status for T0 and T1 thresholds. Leave these pins unconnected if they are not used in the application.

Pin Functions (continued)

PIN		FOUNTAL FUT CIDCUIT	TVDE	DESCRIPTION	
NAME	NO.	EQUIVALENT CIRCUIT	TYPE	DESCRIPTION	
SCLK	58	VA19 Υ	I	Serial Interface Clock This pin functions as the serial-interface clock input which clocks the serial data in and out. The Using the Serial Interface section describes the serial interface in more detail.	
SDI	57		1	Serial Data In This pin functions as the serial-interface data input. The Using the Serial Interface section describes the serial interface in more detail.	
SYNC~	30		I	SYNC~ This pin provides the JESD204B-required synchronizing request input. A logic-low applied to this input initiates a lane alignment sequence. The choice of LVCMOS or differential SYNC~ is selected through bit 6 of the configuration register 0x202h. Connect this input to GND or VA19 if differential SYNC~ input is used.	
SCS	59	GND	I	Serial Chip Select (active low) This pin functions as the serial-interface chip select. The Using the Serial Interface section describes the serial interface in more detail.	
SDO	56	VA19 GND	0	Serial Data Out This pin functions as the serial-interface data output. The Using the Serial Interface section describes the serial interface in more detail.	
DIFFERENTIAL II	NPUT				
DEVCLK+	15 16	VA19	I	Device Clock Input The differential device clock signal must be AC coupled to these pins. The input signal is sampled on the rising edge of CLK.	
SYSREF+	19			SYSREF	
SYSREF-	20	AGND 1 kΩ VA19 VA19	I	The differential periodic waveform on these pins synchronizes the device per JESD204B. If JESD204B subclass 1 synchronization is not required and these inputs are not utilized they may be left unconnected. In that case ensure SysRef_Rcvr_En=0 and SysRef_Pr_En=0.	
SYNC~+	22	$\frac{1}{4}$ $\geq 50 \Omega$		SYNC~ This differential input provides the JESD204B-required synchronizing request input. A differential logic-low applied to these inputs initiates a lane alignment sequence. For differential SYNC~ usage, leave unconnected if SYNC_DIFFSEL = 0. These inputs may be left unconnected if they are not used for the SYNC-function.	
SYNC~-	23	AGND	I

	55				
	5			VNEG	
VNEG	12		I	These pins must be decoupled to ground with a 0.1-µF ceramic capacitor near each pin. These power input pins must be connected to the VNEG_OUT pin with a low resistance path. The connections must be isolated from any noisy digital signals and must also be isolated from the analog input and clock input pins.	
VNEG_OUT	29		0	VNEG_OUT The voltage on this output can range from -1V to +1V. This pin must be decoupled to ground with a 4.7-µF, low ESL, low ESR multi-layer ceramic chip capacitor and connected to the VNEG input pins. This voltage must be isolated from any noisy digital signals, clocks, and the analog input.

Storage temperature	, T _{stg}	·	-65	150	°C

- (1) Reflow temperature profiles are different for lead-free and non-lead-free packages.
- (2) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (3) If Military/Aerospace specified devices are required, please contact the Texas Instruments Sales Office/Distributors for availability and specifications.
- (4) The analog inputs are protected as in the following circuit. Input-voltage magnitudes beyond the *Absolute Maximum Ratings* may damage this device.

(5) When the input voltage at any pin (other than VIN+ or VIN-) exceeds the power supply limits (that is, less than GND or greater than VA19), the current at that pin must be limited to 25 mA. The 100-mA maximum package input current rating limits the number of pins that can safely exceed the power supplies. This limit is not placed upon the power pins or thermal pad (GND).

6.2 ESD Ratings

			VALUE	UNIT
		Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins (1)	±2000	
V _(ESD)	Electrostatic discharge	Charged device model (CDM), per JEDEC specification JESD22-C101, all pins (2)	±500	V

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

All voltages are measured with respect to GND = 0 V, unless otherwise specified.

			MIN	MAX	UNIT
V	Cumply voltogo	1.2-V supply: VA12, VD12	1.14	1.26	V
V_{DD}	Supply voltage	1.9-V supply: VA19	1.8	2	V
	Supply sequence (power-up and	d power-down)		1.9 supply ≥ 1.2 supply	V
V_{CMI}	Analog input common mode vol	tage	V _(VCMO) - 0.15	V _(VCMO) + 0.15	V
	VIN+, VIN- voltage (maintaining	common mode)	0	V _(VA19)	V
	DEVCLK±, SYSREF±, ~SYNC±	pin voltage range	0	V _(VA19)	V
V _{ID(CLK)}	Differential DEVCLK±, SYSREF	±, ~SYNC± amplitude	0.4	2	V_{PP}
V _{CM(CLK)}	SYSREF±, ~SYNC± Common N	Node	0.64	1.1	V
T _A	Ambient temperature		-40	85	°C

6.4 Thermal Information

		LM15851	
	THERMAL METRIC ⁽¹⁾	NKE (VQFN)	UNIT
		68 PINS	
$R_{\theta JA}$	Thermal resistance, junction-to-ambient	19.8	°C/W
R _θ JCbot	Thermal resistance, junction-to-case (bottom)	2.7	°C/W
ΨЈВ	Characterization parameter, junction-to-board	9.1	°C/W

For more information about traditional and new thermal metrics, see the Semiconductor and IC Package Thermal Metrics application report.

6.5 Electrical Characteristics

Unless otherwise noted, these specifications apply for $V_{(VA12)} = V_{(VD12)} = 1.2 \text{ V}$, $V_{(VA19)} = 1.9 \text{ V}$, VIN full scale range at default setting (725 mV_{PP}), VIN = -1 dBFS, differential AC-coupled sinewave input clock, $f_{(DEVCLK)} = 4 \text{ GHz}$ at 0.5 V_{PP} with 50% duty cycle, $R_{(RBIAS)} = 3.3 \text{ k}\Omega$ ±0.1%, after a foreground (FG) mode calibration with timing calibration enabled. Typical values are at $T_A = 25^{\circ}\text{C}$. (1)(2)

	PARAMETER	TEST CON	DITIONS	MIN	TYP	MAX	UNIT
DYNAMIC P	PERFORMANCE CHARACTERISTIC	cs care					
IMD ₃	Third-order intermodulation distortion	F1 = 2110 MHz at -13 dBFS F2 = 2170 MHz at -13 dBFS			-64		dBc
DECIMATE-	BY-4 MODE						
			T _A = 25°C		59.9		
SNR1	Signal-to-noise ratio, integrated across DDC alias protected output bandwidth	F_{IN} = 600 MHz, -1 dBFS, decimate-by-4 mode	$T_A = T_{MIN}$ to T_{MAX}	56.2			
			T _A = 25°C, calibration = BG		59.2		dBFS
	Input frequency-dependent interleaving spurs included		$T_A = T_{MIN}$ to T_{MAX} , calibration = BG	53.3			
	3.4.	F _{IN} = 2400 MHz, -1 dBFS, decimate-by-4 n	node		56.4		
			T _A = 25°C ⁽³⁾		60.1		
	Signal-to-noise ratio, integrated across DDC alias	F _{IN} = 600 MHz, -1 dBFS, decimate-by-4	$T_A = T_{MIN} \text{ to } T_{MAX}^{(3)}$	56.7			
SNR2	protected output bandwidth	mode	T _A = 25°C, calibration = BG ⁽³⁾		60.2		dBFS
	Input frequency-dependent interleaving spurs excluded		T _A = T _{MIN} to T _{MAX} , calibration = BG ⁽³⁾	56.7			
	moneuving opure exercises	F _{IN} = 2400 MHz, -1 dBFS, decimate-by-4 n	node ⁽³⁾		57		

⁽¹⁾ To ensure accuracy, the VA19, VA12, and VD12 pins are required to be well bypassed. Each supply pin must be decoupled with one or more bypass capacitors.

⁽²⁾ Interleave related fixed frequency spurs at f_S / 4 and f_S / 2 are excluded from all SNR, SINAD, ENOB and SFDR specifications. The magnitude of these spurs is provided separately.

⁽³⁾ Interleave related spurs at f_S/2 - F_{IN}, f_S/4 + F_{IN} and f_S/4 - F_{IN} are excluded from these performance calculations. The magnitude of these spurs is provided separately.

Unless otherwise noted, these specifications apply for $V_{(VA12)} = V_{(VD12)} = 1.2 \text{ V}$, $V_{(VA19)} = 1.9 \text{ V}$, VIN full scale range at default setting (725 mV_{PP}), VIN = -1 dBFS, differential AC-coupled sinewave input clock, $f_{(DEVCLK)} = 4 \text{ GHz}$ at 0.5 V_{PP} with 50% duty cycle, $R_{(RBIAS)} = 3.3 \text{ k}\Omega$ ±0.1%, after a foreground (FG) mode calibration with timing calibration enabled. Typical values are at $T_A = 25^{\circ}\text{C}$.

7 Detailed Description

7.1 Overview

The LM15851 device is an ultra-wideband sampling and digital tuning subsystem. The device combines a very-wideband and high sampling-rate ADC front-end with a configurable digital-down conversion block. This combination provides the necessary features to facilitate the development of flexible software-defined radio products for a wide range of communications applications.

The LM15851 device is based on an ultra high-speed ADC core. The core uses an interleaved calibrated folding and interpolating architecture that results in very high sampling rate, very good dynamic performance, and relatively low-power consumption. This ADC core is followed by a configurable DDC block which is implemented on a small geometry CMOS. The DDC block provides a range of decimation settings that allow the product to work in ultra-wideband, wideband, and more-narrow-band receive systems. The output data from the DDC block is transmitted through a JESD204B-compatible multi-lane serial-output system. This system minimizes the number of data pairs required to convey the output data to the downstream processing circuitry.

Functional Block Diagram (continued)

Figure 31. DDC Details Block Diagram

7.3 Feature Description

7.3.1 Signal Acquisition

The analog input is sampled on the rising edge of CLK and the digital equivalent of that data is available in the serialized datastream $t_{(LAT)}$ or $t_{(LAT)}$ input clock cycles later.

The LM15851 device converts as long as the input clock signal is present. The fully-differential comparator design and the innovative design of the sample-and-hold amplifier, together with calibration, enables very good performance at input frequencies beyond 3 GHz. The LM15851 data is output on a high-speed serial JESD204B interface.

7.3.2 The Analog Inputs

A differential input signal must be used to drive the LM15851 device. Operation with a single-ended signal is not recommended as performance suffers. The input signals can be either be AC coupled or DC coupled. The analog inputs are internally connected to the V_{CMO} bias voltage. When DC-coupled input signals are used, the common mode voltage of the applied signal must meet the device Input common mode requirements. See V_{CMI} in the *Recommended Operating Conditions* table.

The full-scale input range for each converter can be adjusted through the serial interface. See the *Full Scale Range Adjust* section.

The buffered analog inputs simplify the task of driving these inputs and the RC pole that is generally used at sampling ADC inputs is not required. If an amplifier circuit before the ADC is desired, use care when selecting an amplifier with adequate noise and distortion performance and adequate gain at the frequencies used for the application. If gain is not required, a balun (balanced-to-unbalanced transformer) is generally used to provide single ended (SE) to differential conversion.

The input impedance of VIN± consists of two $50-\Omega$ resistors in series between the inputs and a capacitance from each of these inputs to ground. A resistance of approximately $20~k\Omega$ exists from the center point of the $50-\Omega$ resistors to the on-chip V_{CMO} providing self-biasing for AC-coupled applications.

Performance is good in both DC-coupled mode and AC coupled mode, provided the common-mode voltage at the analog input is within specifications.

Feature Description (continued)

7.3.2.1 Input Clamp

The LM15851 maximum DC input voltage is limited to the range 0 to 2 V to prevent damage to the device. To help maintain these limits, an active input clamping circuit is incorporated which sources or sinks input currents up to ±50 mA. The clamping circuit is enabled by default and is controlled via the Input_Clamp_EN bit (register 0x034, bit 5). The protection provided by this circuit is limited as follows:

- Shunt current-clamping is only effective for non-zero source impedances.
- At frequencies above 3 GHz the clamping is ineffective because of the finite turn-on and turn-off time of the switch.

With these limitations in mind, analysis has been done to determine the allowable input signal levels as a function of input frequency when the Input Clamp is enabled, assuming the source impedance matches the input impedance of the device (100- Ω differential). This information is incorporated in the *Absolute Maximum Ratings* table.

7.3.2.2 AC Coupled Input Usage

The easiest way to accomplish SE-to-differential conversion for AC-coupled signals is with an appropriate balun.

Figure 32. Single-Ended-to-Differential Signal Conversion With a Balun

Figure 32 shows a generic depiction of a SE-to-differential signal conversion using a balun. The circuitry specific to the balun depends on the type of balun selected and the overall board layout. TI recommends that the system designer contact the manufacturer of the selected balun to aid in designing the best performing single-ended to differential conversion circuit using that particular balun.

When selecting a balun, understanding the input architecture of the ADC is important. Specific balun parameters must be considered. The balun must match the impedance of the analog source to the on-chip $100-\Omega$ differential input termination of the LM15851 device. The range of this input termination resistor is described in the *Electrical Characteristics* table as the specification R_{ID} .

Also, as a result of the ADC architecture, the phase and amplitude balance are important. The lowest possible phase and amplitude imbalance is desired when selecting a balun. The phase imbalance must be no more than ±2.5° and the amplitude imbalance must be limited to less than 1 dB at the desired input frequency range.

Finally, when selecting a balun, the voltage standing-wave ratio (VSWR), bandwidth, and insertion loss of the balun must also be considered. The VSWR aids in determining the overall transmission line termination capability of the balun when interfacing to the ADC input. The insertion loss must be considered so that the signal at the balun output is within the specified input range of the ADC as described in the *Electrical Characteristics* table as the specification $V_{\rm ID}$.

Table 1 lists the recommended baluns for specific signal frequency ranges.

Table 1. Balun Recommendations

MINIMUM FREQUENCY (MHz)	MAXIMUM FREQUENCY (MHz)	IMPEDANCE RATIO	PART NUMBER	MANUFACTURER
4.5	3000	1:1	TC1-1-13MA+	Mini-Circuits
400	3000	1:2	B0430J50100AHF	Anaren
30	1800	1:2	ADTL2-18+	Mini-Circuits
10	4000	1:2	TCM2-43X+	Mini-Circuits

7.3.2.3 DC Coupled Input Usage

When a DC-coupled signal source is used, the common mode voltage of the applied signal must be within a specified range (V_{CMI}). To achieve this range, the common mode of the driver should be based on the VCMO output provided for this purpose.

Full-scale distortion performance degrades as the input common-mode voltage deviates from VCMO. Therefore, maintaining the input common-mode voltage within the V_{CMI} range is important.

Table 2 lists the recommended amplifiers for DC-coupled usage or if AC-coupling with gain is required.

		•		
-3-dB BANDWIDTH (MHz)	MIN GAIN (dB)	MAX GAIN (dB)	GAIN TYPE	PART NUMBER
7000	16	16	Fixed	LMH3401
2800	0	17	Resistor set	LMH6554
2400	6	26	Digital programmable	LMH6881
900	-1.16	38.8	Digital programmable	LMH6518

Table 2. Amplifier Recommendations

7.3.2.4 Handling Single-Ended Input Signals

The LM15851 device has no provision to adequately process single-ended input signals. The best way to handle single-ended signals is to convert these signals to balanced differential signals before presenting the signals to the ADC.

7.3.3 Clocking

The LM15851 device has a differential clock input, DEVCLK+ and DEVCLK-, that must be driven with an AC-coupled differential clock-signal. The clock inputs are internally terminated and biased. The input clock signal must be capacitively coupled to the clock pins as shown in Figure 33.

Figure 33. Differential Sample-Clock Connection

The differential sample-clock line pair must have a characteristic impedance of 100 Ω and must be terminated at the clock source of that 100- Ω characteristic impedance. The input clock line must be as short and direct as possible. The LM15851 clock input is internally terminated with an untrimmed 100- Ω resistance.

Insufficient input clock levels results in poor dynamic performance. Excessively-high input-clock levels can cause a change in the analog-input offset voltage. To avoid these issues, maintain the input clock level within the range specified in the *Electrical Characteristics* table.

The low times and high times of the input clock signal can affect the performance of any ADC. The LM15851 device features a duty-cycle clock-correction circuit which maintains performance over temperature. The ADC meets the performance specification when the input clock high times and low times are maintained as specified in the *Electrical Characteristics* table.

High-speed high-performance ADCs such as the LM15851 device require a very-stable input clock-signal with minimum phase noise or jitter. ADC jitter requirements are defined by the ADC resolution or ENOB (effective number of bits), maximum ADC input frequency, and the input signal amplitude relative to the ADC input full-scale range. Use Equation 1 to calculate the maximum jitter (the sum of the jitter from all sources) allowed to prevent a jitter-induced reduction in SNR.

$$RMS_{tot(J)} = \frac{V_{FSR}}{V_{I(PP)}} \times \frac{1}{\left(2^{(n+1)} \times \pi \times F_{IN}\right)}$$

where

- RMS_{tot(J)} is the RMS total of all jitter sources in seconds
- V_{I(PP)} is the peak-to-peak analog input signal
- V_{FSR} is the full-scale range of the ADC
- · n is the ADC resolution in bits
- F_{IN} is the maximum input frequency, in Hertz, at the ADC analog input

(1)

Note that the maximum jitter previously described is the root sum square (RSS) of the jitter from all sources, including that from the clock source, the jitter added by noise coupling at board level and that added internally by the ADC clock circuitry, in addition to any jitter added to the input signal. Because the effective jitter added by the ADC is beyond user control, the best option is to minimize the jitter from the clock source, the sum of the externally-added input clock jitter and the jitter added by any circuitry to the analog signal.

Input clock amplitudes above those specified in the *Recommended Operating Conditions* table can result in increased input-offset voltage. Increased input-offset voltage causes the converter to produce an output code other than the expected 2048 when both input pins are at the same potential.

7.3.4 Over-Range Function

To ensure that system-gain management has the quickest-possible response time, a low-latency configurable over-range function is included. The over-range function works by monitoring the raw 12-bit samples exiting the ADC module. The upper 8 bits of the magnitude of the ADC data are checked against two programmable thresholds, OVR_T0 and OVR_T1. The following table lists how a raw ADC value is converted to an absolute value for a comparison of the thresholds.

ADC SAMPLE (OFFSET BINARY)	ADC SAMPLE (2's COMPLEMENT)	ABSOLUTE VALUE	UPPER 8 BITS USED FOR COMPARISON
1111 1111 1111 (4095)	0111 1111 1111 (+2047)	111 1111 1111 (2047)	1111 1111 (255)
1111 1111 0000 (4080)	0111 1111 0000 (+2032)	111 1111 0000 (2032)	1111 1110 (254)
1000 0000 0000 (2048)	0000 0000 0000 (0)	000 0000 0000 (0)	0000 0000 (0)
0000 0001 0000 (16)	1000 0001 0000 (-2032)	111 1111 0000 (2032)	1111 1110 (254)
0000 0000 0000 (0)	1000 0000 0000 (-2048)	111 1111 1111 (2047)	1111 1111 (255)

If the upper 8 bits of the absolute value equal or exceed the OVR_T0 or OVR_T1 threshold during the monitoring period, then the over-range bit associated with the threshold is set to 1, otherwise the over-range bit is 0. The resulting over-range bits are embedded into the complex output data samples and output on OR_T0 and OR_T1. Table 3 lists the outputs, related data samples, threshold settings and the monitoring period equation.

Table 3. Threshold and Monitor Period for Embedded OR Bits

EMBEDDED OVER-RANGE OUTPUTS	ASSOCIATED THRESHOLD	ASSOCIATED SAMPLES	MONITORING PERIOD (ADC SAMPLES)
OR_T0	OVR_T0	In-Phase (I) samples	20VR_N(1)
OR_T1	OVR_T1	Quadrature (Q) samples	2

(1) OVR_N is the monitoring period register setting.

Table 4. Over-Range Monitoring Period

OVR_N	MONITORING PERIOD
0	1
1	2
2	4
3	8
4	16
5	32
6	64
7	128

Typically, the OVR_T0 threshold can be set near the full-scale value (228 for example). When the threshold is triggered, a typical system can turn down the system gain to avoid clipping. The OVR_T1 threshold can be set much lower. For example, the OVR_T1 threshold can be set to 64 (-12 dBFS). If the input signal is strong, the OVR_T1 threshold is tripped occasionally. If the input is quite weak, the threshold is never tripped. The downstream logic device monitors the OVR_T1 bit. If OVR_T1 stays low for an extended period of time, then the system gain can be increased until the threshold is occasionally tripped (meaning the peak level of the signal is above -12 dBFS).

The OR_T0 threshold is embedded as the LSB along with the upper 15 bits of every complex I sample. The OR_T1 threshold is embedded as the LSB along with the upper 15 bits of every complex Q sample.

7.3.5 ADC Core Features

7.3.5.1 The Reference Voltage

The reference voltage for the LM15851 device is derived from an internal bandgap reference. A buffered version of the reference voltage is available at the VBG pin for user convenience. This output has an output-current capability of $\pm 100~\mu A$. The VBG output must be buffered if more current is required. No provision exists for the use of an external reference voltage, but the full-scale input voltage can be adjusted through the full-scale-range register settings.

7.3.5.2 Common-Mode Voltage Generation

The internal reference voltage is used to generate a stable common-mode voltage reference for the analog Inputs and the DEVCLK and SYSREF differential-clock inputs.

7.3.5.3 Bias Current Generation

An external bias resistor, in combination with the on-chip voltage reference is used to provide an accurate and stable source of bias currents for internal circuitry. Using an external accurate resistor minimizes variation in device power consumption and performance.

7.3.5.4 Full Scale Range Adjust

The ADC input full-scale range can be adjusted through the GAIN_FS register setting (registers 0x022 and 0x023). The adjustment range is approximately 500 mV_{PP} to 950 mV_{PP}. The full-scale range adjustment is useful for matching the input-signal amplitude to the ADC full scale, or to match the full-scale range of multiple ADCs when developing a multi-converter system.

7.3.5.5 Offset Adjust

The ADC-input offset voltage can be adjusted through the OFFSET_FS register setting (registers 0x025 and 0x026). The adjustment range is approximately 28 mV to -28 mV differential.

NOTE

Offset adjust has no effect when background calibration mode is enabled.

7.3.5.6 Power-Down

The power-down bit (PD) allows the LM15851 device to be entirely powered down. The serial data output drivers are disabled when PD is high. When the device returns to normal operation, the JESD204 link must be reestablished, and the ADC pipeline and decimation filters contain meaningless information and must be flushed.

7.3.5.7 Built-In Temperature Monitor Diode

A built-in thermal monitoring diode junction is made available on the TDIODE+ and TDIODE- pins. This diode facilitates temperature monitoring and characterization of the device in higher ambient temperature environments. While the on-chip diode is not highly characterized, the diode can be used effectively by performing a baseline measurement at a known ambient or board temperature with the device in power-down (PD) mode. Recommended monitoring ICs include the LM95233 device and similar remote-diode temperature monitoring products from Texas Instruments.

7.3.6 Digital Down Converter (DDC)

The digitized data is the input to the digital down-converter block. This block provides frequency conversion and decimation filtering to allow a specific range of frequencies to be selected and output in the digital data stream.

7.3.6.1 NCO/Mixer

The DDC contains a complex numerically-controlled oscillator and a complex mixer. The oscillator generates a complex exponential sequence shown in Equation 2.

$$x[n] = e^{j \cdot o n} \tag{2}$$

The frequency (ω) is specified by the a 32-bit register setting. The complex exponential sequence is multiplied by the real input from the ADC to mix the desired carrier down to 0 Hz.

7.3.6.2 NCO Settings

7.3.6.2.1 NCO Frequency Phase Selection

Within the DDC, eight different frequency and phase settings are always available for use. Each of the eight settings uses a different phase accumulator within the NCO. Because all eight phase accumulators are continuously running independently, rapid switching between different NCO frequencies is possible allowing rapid tuning of different signals.

The specific frequency-phase pair in use is selected through either the NCO_x input pins, or the NCO_SEL configuration bits (register 0x20D, bits 2:0). The CFG_MODE bit (register 0x20C, bit 0) is used to choose whether the input pins or selection bits are used. When the CFG_MODE bit is set to 0, the NCO_x input pins select the active NCO frequency and phase setting. When the CFG_MODE bit is set to 1, the NCO_SEL register settings select the active NCO frequency and phase setting.

The frequency for each phase accumulator is programmed independently through the NCO_FREQn (and optionally NCO_RDIV) settings. The phase offset for each accumulator is programmed independently through the NCO_PHASEn register settings.

7.3.6.2.2 NCO_0, NCO_1, and NCO_2 (NCO_x)

When the CFG_MODE bit is set to 0, the state of these three inputs determines the active NCO frequency and phase accumulator settings.

7.3.6.2.3 NCO_SEL Bits (2:0)

When the CFG_MODE bit is set to 1, the state of these register bits determines the active NCO frequency and phase accumulator settings.

7.3.6.2.4 NCO Frequency Setting (Eight Total)

7.3.6.2.4.1 Basic NCO Frequency-Setting Mode

In basic NCO frequency-setting mode, the NCO frequency setting is set by the 32-bit register value, NCO_FREQn (n = preset 0 trough 7, see the NCO Frequency (Preset x) Register section).

$$(n = 0 - 7) f_{(NCO)} = NCO_FREQn \times 2^{-32} \times f_{(DEVCLK)}$$
(3)

NOTE

Changing the register setting after the JESD204B interface is running results in nondeterministic NCO phase. If deterministic phase is required, the JESD204B link must be re-initialized after changing the register setting. See the Multiple ADC Synchronization section.

7.3.6.2.4.2 Rational NCO Frequency Setting Mode

In basic NCO frequency mode, the frequency step size is very small and many frequencies can be synthesized, but sometimes an application requires very specific frequencies that fall between two frequency steps. For example with $f_{\rm S}$ equal to 2457.6 MHz and a desired $f_{\rm (NCO)}$ equal to 5.02 MHz the value for NCO_FREQ is 8773085.867. Truncating the fractional portion results in an $f_{\rm (NCO)}$ equal to 5.0199995 MHz, which is not the desired frequency.

To produce the desired frequency, the NCO_RDIV parameter is used to force the phase accumulator to arrive at specific frequencies without error. First, select a frequency step size $(f_{(STEP)})$ that is appropriate for the NCO frequency steps required. The typical value of $f_{(STEP)}$ is 10 kHz. Next, program the NCO_RDIV value according to Equation 4.

$$NCO_RDIV = \frac{\left(\frac{f_{(DEVCLK)}}{f_{(STEP)}}\right)}{128}$$
(4)

The result of Equation 4 must be an integer value. If the value is not an integer, adjust either of the parameters until the result in an integer value.

For example, select a value of 1920 for NCO_RDIV.

NOTE

NCO_RDIV values larger than 8192 can degrade the NCO SFDR performance and are not recommended.

Now use Equation 5 to calculate the NCO_FREQ register value.

NCO_FREQ = round ×
$$\left(\frac{2^{25} \times N}{NCO_RDIV}\right)$$
 (5)

Alternatively, the following equations can be used:

Copyright © 2014-2017, Texas Instruments Incorporated

$$N = \frac{f_{(NCO)}}{f_{(STEP)}}$$

$$NCO_FREQ = round \times \left(\frac{2^{25} \times N}{NCO_RDIV}\right)$$
(6)

$$NCO_FREQ = round \times \left(\frac{2^{23} \times N}{NCO_RDIV}\right)$$
(7)

(8)

Table 5. Common NCO RDIV Values (For 10-kHz Frequency Steps)

$f_{(DEVCLK)}$ (MHz)	NCO_RDIV
3686.4	2880
3072	2400
2949.12	2304
2457.6	1920
1966.08	1536
1474.56	1152
1228.8	960

7.3.6.2.5 NCO Phase-Offset Setting (Eight Total)

The NCO phase-offset setting is set by the 16-bit register value NCO_PHASEn (n = preset 0 trough 7, see the NCO Phase (Preset x) Register section). The value is left-justified into a 32-bit field and then added to the phase accumulator.

Use Equation 8 to calculate the phase offset in radians.

NCO_PHASEn ×
$$2^{-16}$$
 × 2 × π

NOTE

Changing the register setting after the JESD204B interface is running results in nondeterministic NCO phase. If deterministic phase is required, the JESD204B link must be re-initialized after changing the register setting. See Multiple ADC Synchronization.

7.3.6.2.6 Programmable DDC Delay

The DDC Filter elements incorporate a programmable sample delay. The delay can be programmed from 0 to (decimation setting - 0.5) ADC sample periods. The delay step-size is 0.5 ADC sample periods. The delay settings are programmed through the DDC_DLYn parameter.

Table 6. Programmable DDC Delay Range

D (Decimation Setting)	Min Delay (t _(DEVCLK))	Max Delay (t _(DEVCLK))
4	0	3.5
8	0	7.5
10	0	9.5
16	0	15.5
20	0	19.5
32	0	31.5

7.3.6.3 Decimation Filters

The decimation filters are arranged to provide a programmable overall decimation of 4, 8, 10, 16, 20, or 32. The input and output of each filter is complex. The output data consists of 15-bit complex baseband information. Table 7 lists the effective output sample rates.

Table 7. Output Sample Rates

	COMPLEX SAMPLE OUTPUT RATE AND RESULTING BANDWIDTH (OUTPUT SAMPLE = 15-BIT I + 15-BIT Q + 2-BIT OR)						
DECIMATION		$f_{(DEVCLK)}$		f _(DEVCLK) = 4000 MHz			
SETTING	OUTPUT RATE (MSPS)	RAW OUTPUT BANDWIDTH (MHz)	ALIAS PROTECTED BANDWIDTH (MHz)	OUTPUT RATE (MSPS)	RAW OUTPUT BANDWIDTH (MHz)	ALIAS PROTECTED BANDWIDTH (MHz)	
4	f _(DEVCLK) / 4	f _(DEVCLK) / 4	$0.8 \times f_{(DEVCLK)} / 4$	1000	1000	800	
8	f _(DEVCLK) / 8	$f_{(DEVCLK)}N$ / 8	$0.8 \times f_{(DEVCLK)} / 8$	500	500	400	
10	f _(DEVCLK) / 10	$f_{(DEVCLK)}$ / 10	$0.8 \times f_{(DEVCLK)} / 10$	400	400	320	
16	f _(DEVCLK) / 16	$f_{(DEVCLK)}$ / 16	$0.8 \times f_{(DEVCLK)} / 16$	250	250	200	
20	f _(DEVCLK) / 20	f _(DEVCLK) / 20	$0.8 \times f_{(DEVCLK)} / 20$	200	200	160	
32	f _(DEVCLK) / 32	f _(DEVCLK) / 32	$0.8 \times f_{(DEVCLK)} / 32$	125	125	100	

For maximum efficiency a group of high speed filter blocks are implemented with specific blocks used for each decimation setting. The first table below describes the combination of filter blocks used for each decimation setting. The next table lists the coefficient details and decimation factor of each filter block.

Table 8. Decimation Mode Filter Usage

Decimation Setting	Filter Blocks Used
4	CS19, CS55
8	CS11, CS15, CS55
10	CS11, CS139
16	CS7, CS11, CS15, CS55
20	CS7, CS11, CS139
32	CS7, CS7, CS11, CS15, CS55

Table 9. Filter Coefficient Details

7.3.6.4 DDC Output Data

The DDC output data consist of 15-bit complex data plus the two over-range threshold-detection control bits. The following table lists the data format:

	16-BIT OUTPUT WORD															
CHANNEL	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
I	DDC Output In-Phase (I) 15 bit														OR_T0	
Q	DDC Output Quadrature (Q) 15 bit														OR_T1	

7.3.6.5 Decimation Settings

7.3.6.5.1 Decimation Factor

The decimation setting is adjustable over the following settings:

- Decimate-by-4
- Decimate-by-8
- Decimate-by-10
- Decimate-by-16
- Decimate-by-20
- Decimate-by-32

NOTE

Because the output format is complex I+Q, the effective output bandwidth is approximately two-times the value for a *real* output with the same decimation factor.

7.3.6.5.2 DDC Gain Boost

The DDC gain boost (register 0x200, bit 4) provides additional gain through the DDC block. With a setting of 1 the final filter has 6.02-dB gain. With a setting of 0, the final filter has a 0-dB gain. This setting is recommended when the NCO is set near DC.

7.3.7 Data Outputs

The data outputs (DSx±) are very high-speed differential outputs and conform to the JESD204B JEDEC standard. A CML (current-mode logic)-type output driver is used for each output pair. Output pre-emphasis is adjustable to compensate for longer PCB-trace lengths.

7.3.7.1 The Digital Outputs

The LM15851 output data is transmitted on up to five high-speed serial-data lanes. The output data from the DDC is formatted to the five lanes, 8b10b encoded, and serialized. Up to four different serial output rates are possible depending on the decimation mode setting: 1x, 1.25x, 2x, and 2.5x. In 1x mode, the output serializers run at the same bit rate as the frequency of the applied DEVCLK. In 1.25x mode, the output serializers run at a bit rate that is 1.25-times that of the applied DEVCLK, and so on. For example, for a 1.6-GHz input DEVCLK, the output rates are 1.6 Gbps in 1x mode, 2 Gbps in 1.25x mode, 3.2 Gbps in 2x mode and 4 Gbps in 2.5x mode.

7.3.7.2 JESD204B Interface Features and Settings

7.3.7.2.1 Scrambler Enable

Scrambling randomizes the 8b10b encoded data, spreading the frequency content of the data interface. This reduces the peak EMI energy at any given frequency reducing the possibility of feedback to the device inputs impacting performance. The scrambler is disabled by default and is enabled via SCR (register 0x201, bit 7).

7.3.7.2.2 Frames Per Multi-Frame (K-1)

The frames per multi-frame (K) setting can be adjusted within constraints that are dependant on the selected decimation (D) and serial rate (DDR) settings. The K-minus-1 (KM1) register setting (register 0x201, bits 6:2) must be one less than the desired K setting.

7.3.7.2.3 DDR

The serial rate can be either $1f_{(CLK)}$ (DDR = 0) or $2f_{(CLK)}$ (DDR = 1).

7.3.7.2.4 JESD Enable

The JESD interface must be disabled (JESD_EN is set to 0) while any of the other JESD parameters are changed. While JESD_EN is set 0 the block is held in reset and the serializers are powered down. The clocks for this section are also gated off to further save power. When the parameters have been set as desired the JESD block can be enabled (JESD_EN is set to 1).

7.3.7.2.5 JESD Test Modes

Several different JESD204B test modes are available to assist in link verification and debugging. The list of modes follows.

NOTE

PRBS test signals are output directly, without 8b10b encoding.

- Normal operation
- PRBS7 test mode
- PRBS15 test mode
- PRBS23 test mode
- Ramp test mode
- Short or long transport-layer test mode
- D21.5 test mode
- K28.5 test mode
- Repeated ILA test mode
- Modified RPAT test mode
- Serial-outputs differential 0 test mode
- Serial-outputs differential 1 test mode

7.3.7.2.6 Configurable Pre-Emphasis

The high-speed serial-output drivers incorporate a configurable pre-emphasis feature. This feature allows the output drive waveform to be optimized for different PCB materials and signal transmission distances. The pre-emphasis setting is adjusted through the serializer pre-emphasis setting in register 0x040, bits 3 to 0. The default setting is 4d. Higher values will increase the pre-emphasis to compensate for more lossy PCB materials. This adjustment is best used in conjunction with an eye-diagram analysis capability in the receiver. The pre-emphasis setting should be adjusted to optimize the eye-opening for the hardware configuration and line rates needed.

7.3.7.2.7 Serial Output-Data Formatting

Output data is generated by the DDC then formatted according to the selected decimation and output rate settings. When less than the maximum of five lanes are active, lanes are disabled beginning with the highest numerical lanes. For example when only two lanes are active, lanes 0 and 1 are active, while all higher lanes are inactive.

Table 10. Parameter Definitions

PARAMETER	DESCRIPTION	USER CONFIGURED OR DERIVED	STANDARD JESD204B LINK PARAMETER
D	Decimation factor, determined by DMODE register	User	No
DDR	Serial line rate: 1 = DDR rate (2x), 0 = SDR rate (1x)	User	No
P54	Enable 5/4 PLL to increase line rate by 1.25x.	User	No
	0 = no PLL (1x), 1 = enable PLL (1.25x)		
K	Number of frames per multiframe	User	Yes
N	Bits per sample (before adding control bits and tails bits)	Derived	Yes
CS	Control bits per sample	Derived	Yes
N'	Bits per sample (after adding control bits and tail bits). Must be a multiple of 4.	Derived	Yes
L	Number of serial lanes	Derived	Yes
F	Number of octets (bytes) per frame (per lane)	Derived	Yes
М	Number of (logical) converters	Derived	Yes
S	Number of samples per converter per frame	Derived	Yes
CF	Number of control words per frame	Derived	Yes
HD	1=High density mode (samples may be broken across lanes), 0 = normal mode (samples may not be broken across lanes)	Derived	Yes
KS	Legal adjustment step for K, to ensure that the multi-frame clock is a sub-harmonic of other internal clocks	Derived	No

The formatted data is 8b10b encoded and output on the serial lanes. The 8b10b encoding provides a number of specific benefits, including:

- Standard encoding format. Therefore the IP is readily available in off-the-shelf FPGAs and ASIC building blocks.
- Inherent DC balance allows AC coupling of lanes with small on-chip capacitors
- Inherent error checking

7.3.7.2.8 JESD204B Synchronization Features

The JESD204B standard defines methods for synchronization and deterministic latency in a multi-converter system. This device is a JESD204B Subclass 1 device and conforms to the various aspects of link operation as described in section 5.3.3 of the JESD204B standard. The specific signals used to achieve link operation are described briefly in the following sections.

7.3.7.2.9 SYSREF

The SYSREF is a periodic signal which is sampled by the device clock, and is used to align the boundary of the local multi-frame clock inside the data converter. SYSREF

is required to be a sub-harmonic of the LMFC internal timing. To meet this requirement, the timing of SYSREF is dependent on the device clock frequency and the LMFC frequency as determined by the selected DDC decimation and frames per multi-frame settings. This clock is typically in the range of 10 MHz to 300 MHz. See the *Multiple ADC Synchronization* section for more details on SYSREF timing requirements.

7.3.7.2.10 SYNC~

SYNC~ is asserted by the receiver to initiate a synchronization event.

Single ended and differential SYNC~ inputs are provided. The SYNC_DIFFSEL bit (register 0x202, bit 6) is used to select which input is used. . To assert SYNC~, a logic low is applied. To deassert SYNC~ a logic high is applied.

7.3.7.2.11 Code-Group Synchronization

Code-group synchronization is achieved using the following process:

- The receiver issues a synchronization request through the SYNC~ input
- The transmitter issues a stream of K28.5 symbols

Copyright © 2014–2017, Texas Instruments Incorporated

- The receiver synchronizes and waits for correct reception of at least 4 consecutive K symbols
- The receiver deactivates the synchronization request
- Upon detecting that the receiver has deactivated the SYNC~ pin, the transmitter continues emitting K symbols until the next LMFC boundary (or optionally a later LMFC boundary)
- On the first frame following the selected LMFC boundary the transmitters emit an initial lane-alignment sequence

The initial-lane alignment sequence transmitted by the ADC device is defined in additional detail in JESD204B section 5.3.3.5.

7.3.7.2.12 Multiple ADC Synchronization

The second function for the SYSREF input is to facilitate the precise synchronization of multiple ADCs in a system.

One key challenge is to ensure that this synchronization works is to ensure that the SYSREF inputs are repeatedly captured by the input CLK. Two key elements must occur for the SYSREF inputs to be captured. First, the SYSREF input must be created so that it is synchronous to the input DEVCLK, be an integer subharmonic of the multi-frame (K \times t_(FRAME)) and a repeatable and fixed-phase offset. When this constraint is achieved, repeatedly capturing SYSREF is easier. To further ease this task, the SYSREF signal is routed through a user-adjustable delay which eases the timing requirements with respect to the input DEVCLK signal. The SYSREF delay RDEL is adjusted through bits 3 through 0 in register 0x032.

As long as the SYSREF signal has a fixed timing relationship to DEVCLK, the internal delay can be used to maximize the setup and hold times between the internally delayed SYSREF and the internal DEVCLK signal. These timing relationships are listed in the *Timing Requirements* table. To find the proper delay setting, the RDEL value is adjusted from minimum to maximum while applying SYSREF and monitoring the SysRefDet and Dirty Capture detect bits. The SysRefDet bit is set whenever a rising edge of SYSREF is detected. The Dirty Capture bit is set whenever the setup or hold time between DEVCLK and the delayed SYSREF is insufficient. The SysRefDetClr bit is used to clear the SysRefDet bit. The Clear Dirty Capture bit is used to clear that bit.

This procedure should be followed to determine the range of delay settings where a clean SYSREF capture is achieved. The delay value at the center of the clean capture range must be loaded as the final RDEL setting. Table 29 lists a summary of the control bits that are used and the monitor bits that are read.

BIT NAME	REGISTER ADDRESS	REGISTER BIT	FUNCTION
RDEL	0x032	3:0	Adjust relative delay between DEVCLK and SYSREF
SysRefDet	0x031	7	Detect if a SYSREF rising edge has been captured (not self clearing)
Dirty Capture	0x031	6	Detect if SYSREF rising edge capture failed setup/hold (not self clearing)
SysRefDetClr	0x030	5	Clear SYSREF detection bit
Clear Dirty Capture	0x030	4	Clear Dirty Capture detection bit
SysRef_Rcvr_En	0x030	7	Enable SYSREF receiver. See the CLKGEN_0 descriptions in the <i>Clock Generator Control 0 Register</i> section for more information.
SysRef_Pr_En	0x030	6	Enable SYSREF processing. See the CLKGEN_0 descriptions in the Clock Generator Control 0 Register section for more information.

Table 29. SYSREF Capture Control and Status

One final aspect of multi-device synchronization relates to phase alignment of the NCO phase accumulators when DDC modes are enabled. The NCO phase accumulators are reset during the ILA phase of link startup which means that for multiple ADCs to have NCO phase alignment, all links must be enabled in the same LMFC period. Enabling all links in the same LMFC period requires synchronizing the SYNC~ de-assertion across all data receivers in the system, so that all of the SYNC~ signals are released during the same LMFC period. Using large K values and resulting longer LMFC periods will ease this task, at the expense of potentially higher latency in the receiving device.

7.4 Device Functional Modes

7.4.1 DDC Modes

In the DDC modes (decimation > 1) complex (I,Q) data is output at a lower sample rate as determined by the decimation factor (4, 8, 10, 16, 20, and 32).

7.4.2 Calibration

Calibration adjusts the ADC core to optimize the following device parameters:

- ADC core linearity
- ADC core-to-core offset matching
- ADC core-to-core full-scale range matching
- ADC core 4-way interleave timing

All calibration processes occur internally. Calibration does not require any external signals to be present and works properly as long as the device is maintained within the values listed in the *Recommended Operating Conditions* table.

7.4.2.1 Foreground Calibration Mode

In foreground mode the calibration process interrupts normal ADC operation and no output data is available during this time (the output code is forced to a static value). The calibration process should be repeated if the device temperature changes by more than 20° C to ensure rated performance is maintained. Foreground calibration is initiated by setting the CAL_SFT bit (register 0x050, bit 3) which is self clearing. The foreground calibration process finishes within $t_{(CAL)}$ number of DEVCLK cycles. The process occurs somewhat longer when the timing calibration mode is enabled.

NOTE

Initiating a foreground calibration asynchronously resets the calibration control logic and may glitch internal device clocks. Therefore after setting the CAL_SFT bit clearing and then setting JESD_EN is necessary. If resetting the JESD204B link is undesirable for system reasons, background calibration mode may be preferred.

7.4.2.2 Background Calibration Mode

In background mode an additional ADC core is powered-up for a total of 5 ADC cores. At any given time, one core is off-line and not used for data conversion. This core is calibrated in the background and then placed online simultaneous with another core going off-line for calibration. This process operates continuously without interrupting data flow in the application and ensures that all cores are optimized in performance regardless of any changes of temperature. The background calibration cycle rate is fixed and is not adjustable by the user.

Because of the additional circuitry active in background calibration mode, a slight degradation in performance occurs in comparison to foreground calibration mode at a fixed temperature. As a result of this degradation, using foreground calibration mode is recommended if the expected change in operating temperature is <30°C. Using background calibration mode is recommended if the expected change in operating temperature is >30°C. The exact difference in performance is dependent on the DEVCLK (sampling clock) frequency, and the analog input signal frequency and amplitude. For this reason, device and system performance should be evaluated using both calibration modes before finalizing the choice of calibration mode.

To enable the background calibration feature, set the CAL_BCK bit (register 0x057, bit 0) and the CAL_CONT bit (register 0x057, bit 1). The value written to the register 0x057 to enable background calibration is therefore 0x013h. After writing this value to register 0x057, set the CAL_SFT bit in register 0x050 to perform the one-time foreground calibration to begin the process.

NOTE

The ADC offset-adjust feature has no effect when background calibration mode is enabled.

Device Functional Modes (continued)

7.4.3 Timing Calibration Mode

The timing calibration process optimizes the matching of sample timing for the 4 internally interleaved converters. This process minimize the presence of any timing related interleaving spurs in the captured spectrum. The timing calibration feature is disabled by default, but using this feature is highly recommended. To enable timing calibration, set the T_AUTO bit (register 0x066, bit 0). When this bit is set, the timing calibration performs each time the CAL SFT bit is set.

Table 30. Calibration Cycle Timing for Different Calibration Modes and Options

CAL_CONT, CAL_BCK	T_AUTO	LOW_SIG_EN	INITIAL ONE-TIME CALIBRATION CAL_SFT 0 → 1 (t _{DEVCLK})	BACKGROUND CALIBRATION CYCLE ⁽¹⁾ (ALL CORES) (t _{DEVCLK})
0	0	0	102 E+6	N/A
0	0	1	64 E+6	N/A

7.4.4 Test-Pattern Modes

A number of device test modes are available. These modes insert known patterns of information into the device data path for assistance with system debug, development, or characterization.

7.4.4.1 Serializer Test-Mode Details

Test modes are enabled by setting the appropriate configuration of the JESD204B_TEST setting (Register 0x202, Bits 3:0). Each test mode is described in detail in the following sections. Regardless of the test mode, the serializer outputs are powered up based on the configuration decimation and DDR settings. The test modes should only be enabled while the JESD204B link is disabled.

Figure 34. Test-Mode Insertion Points

7.4.4.2 PRBS Test Modes

The PRBS test modes bypass the 8B10B encoder. These test modes produce pseudo-random bit streams that comply with the ITU-T O.150 specification. These bit streams are used with lab test equipment that can self-synchronize to the bit pattern and therefore the initial phase of the pattern is not defined.

The sequences are defined by a recursive equation. For example, the PRBS7 sequence is defined as shown in Equation 9.

$$y[n] = y[n-6]^{y[n-7]}$$

where

• Bit n is the XOR of bit [n-6] and bit [n-7] which are previously transmitted bits

(9)

Submit Documentation Feedback

Table 31. PBRS Mode Equations

PRBS TEST MODE	SEQUENCE	SEQUENCE LENGTH (bits)
PRBS7	$y[n] = y[n - 6]^{y[n - 7]}$	127
PRBS15	$y[n] = y[n - 14]^{y[n - 15]}$	32767
PRBS23	$y[n] = y[n - 18]^{y[n - 23]}$	8388607

The initial phase of the pattern is unique for each lane.

7.4.4.3 Ramp Test Mode

In the ramp test mode, the JESD204B link layer operates normally, but the transport layer is disabled and the input from the formatter is ignored. After the ILA sequence, each lane transmits an identical octet stream that increments from 0x00 to 0xFF and repeats.

7.4.4.4 Short and Long-Transport Test Mode

The long-transport test mode is available in all DDC modes (decimation > 1). Patterns are generated in accordance with the JESD204B standard and are different for each output format.

Table 32 lists one example of the long transport test pattern:

Table 32. Long Transport Test Pattern - Decimate-by-4, DDR = 1, P54 = 1, K=10

						•	TIME –	→														
CHAR NO.	0	1	2	3	4	5	6	6 7		9	10	11	12	13	14	15	16	17	18	19	20	21

Lane 1	0x0	002	0x0	005	0x8	000	0x8	0x8000		8000	0x8	000	0x8	000	0x8	000	0x8	000	0x8	000	0x0	002
Lane 2	0x0	004	0x0	002	0x8	001	0x8	000	8x0	8000	0x8	000	0x8	000	0x8	000	0x8	000	0x8	000	0x0	004
Lane 3	0x0	004	0x0	004	0x8	000	0x8			8000	0x8	000	0x8	000	0x8	000	0x8	000	0x8	000	0x0	004
	_	ime n	Fra n -	me + 1		ame + 2			-	ame + 4		me + 5	_	me + 6	Fra n -	me + 7	Fra n -	me + 8	Fra n +		Fra n +	me · 10

If multiple devices are all programmed to the transport layer test mode (while JESD_EN = 0), then JESD_EN is set to 1, and then SYSREF is used to align the LMFC of the devices, the patterns will be aligned to the SYSREF event (within the skew budget of JESD204B). For more details see JESD204B, section 5.1.6.3.

7.4.4.5 D21.5 Test Mode

In this test mode, the controller transmits a continuous stream of D21.5 characters (alternating 0s and 1s).

7.4.4.6 K28.5 Test Mode

In this test mode, the controller transmits a continuous stream of K28.5 characters.

7.4.4.7 Repeated ILA Test Mode

In this test mode, the JESD204B link layer operates normally with one exception: when the ILA sequence completes, the sequence repeats indefinitely. Whenever the receiver issues a synchronization request, the transmitter will initiate code group synchronization. Upon completion of code group synchronization, the transmitter will repeatedly transmit the ILA sequence. If there is no active code group synchronization request at the moment the transmitter enters the test mode, the transmitter will behave as if it received one.

7.4.4.8 Modified RPAT Test Mode

A 12-octet repeating pattern is defined in INCITS TR-35-2004. The purpose of this pattern is to generate white spectral content for JESD204B compliance and jitter testing. Table 33 lists the pattern before and after 8b10b encoding.

Table 33. Modified RPAT Pattern Values

7.5 Programming

7.5.1 Using the Serial Interface

The serial interface is accessed using the following four pins: serial clock (SCLK), serial-data in (SDI), serial-data out (SDO), and serial-interface chip-select (SCS). Registers access is enabled through the SCS pin.

- This signal must be asserted low to access a register through the serial interface. Setup and hold times with respect to the SCLK must be observed.
- **SCLK** Serial data input is accepted at the rising edge of this signal. SCLK has no minimum frequency requirement.
- **SDI** Each register access requires a specific 24-bit pattern at this input. This pattern consists of a read-and-write (R/W) bit, register address, and register value. The data is shifted in MSB first. Setup and hold times with respect to the SCLK must be observed (see Figure 2).
- SDO The SDO signal provides the output data requested by a read command. This output is high impedance during write bus cycles and during the read bit and register address portion of read bus cycles.

Each register access consists of 24 bits, as shown in Figure 2. The first bit is high for a read and low for a write.

The next 15 bits are the address of the register that is to be written to. During write operations, the last 8 bits are the data written to the addressed register. During read operations, the last 8 bits on SDI are ignored, and, during this time, the SDO outputs the data from the addressed register. The serial protocol details are illustrated in Figure 35.

Figure 35. Serial Interface Protocol - Single Read / Write

Programming (continued)

7.5.1.1 Streaming Mode

The serial interface supports streaming reads and writes. In this mode, the initial 24 bits of the transaction specifics the access type, register address, and <u>data</u> value as normal. Additional clock cycles of write or read data are immediately transferred, as long as the <u>SCS</u> input is maintained in the asserted (logic low) state. The register address auto increments (default) or decrements for each subsequent 8 bit transfer of the streaming transaction. The ADDR_ASC bit (register 000h, bits 5 and 2) controls whether the address value ascends (increments) or descends (decrements). Streaming mode can be disabled by setting the ADDR_STATIC bit (register 010h, bit 0). The streaming mode transaction details are shown in Figure 36.

Figure 36. Serial Interface Protocol - Streaming Read / Write

See the *Register Map* section for detailed information regarding the registers.

NOTE

The serial interface must not be accessed during calibration of the ADC. Accessing the serial interface during this time impairs the performance of the device until the device is calibrated correctly. Writing or reading the serial registers also reduces dynamic performance of the ADC for the duration of the register access time.

7.6 Register Map

Several groups of registers provide control and configuration options for this device. Each following register description also shows the power-on reset (POR) state of each control bit.

NOTE

All multi-byte registers are arranged in little-endian format (the least-significant byte is stored at the lowest address) unless explicitly stated otherwise.

Bit	Field	Туре	Reset	Description		
15-0	NCO_RDIV	R/W	0x0000h	Sometimes the 32-bit NCO frequency word does not provide the desired frequency step size and can only approximate the desired frequency. This results in a frequency error. Use this register to eliminate the frequency error. Use this equation to compute the proper value to program:		
				$NCO_RDIV = f_S / f_{(STEP)} / 128$		
				where		
				 f_S is the ADC sample rate 		
				• $f_{(STEP)}$ is the desired NCO frequency step size (10)		
				For example, if f_S = 3072 MHz, and $f_{(STEP)}$ = 10 KHz then:		
				$NCO_RDIV = 3072 MHz / 10 KHz / 128 = 2400$ (11)		
				by combination of $f_{\rm S}$ and $f_{\rm (STEP)}$ that results in a fractional value for NCO_RDIV is not supported. Values of NCO_RDIV reger than 8192 can degrade the NCO's SFDR performance and are not recommended. This register is used for all onfiguration presets.

Table 78. NCO_FREQ_x Field Descriptions

Bit	Field	Туре	Reset	Description
31-0	NCO_FREQ_x	R/W	0xC00000 00h	Changing this register after the JESD204B interface is running results in non-deterministic NCO phase. If deterministic phase is required, the JESD204B interface must be re-initialized after changing this register. The NCO frequency ($f_{(NCO)}$) is: $f_{(NCO)} = NCO_FREQ_x \times 2^{-32} \times f_S$
				where
				 f_S is the sampling frequency of the ADC
				 NCO_FREQ_x is the integer value of this register (12)
				This register can be interpreted as signed or unsigned. Use this equation to determine the value to program:
				$NCO_FREQ_x = 2^{32} \times f_{(NCO)} / f_S $ (13)
				If the equation does not result in an integer value, you must choose an alternate frequency step $(f_{(STEP)})$ and program the NCO_RDIV register. Then use one of the following equations to compute NCO_FREQ_x:
				NCO_FREQ_x = round($2^{32} \times f_{(NCO)} / f_S$) (14)
				NCO_FREQ_x = round($2^{25} \times f_{(NCO)} / f_{(STEP)} / NCO_RDIV$) (15)

7.6.1.7.14 NCO Phase (Preset x) Register (address = see Table 65) [reset = see Table 65]

				This register can be interpreted as signed or unsigned.	

7.6.1.7.15 DDC Delay (Preset x) Register (address = see Table 65) [reset = see Table 65]

Figure 76. DDC Delay (Preset) Register (DDC_DLY_x)

7	6	5 4		3	2	1	0
DDC_DLY_x							
R/W-0xFFh							

Table 80. DDC_DLY_x Field Descriptions

Bit	Field	Туре	Reset	Description
7-0	DDC_DLY_x	R/W	0xFFh	DDC delay for configuration preset 0 This register provides fine adjustments to the DDC group delay. The step size is one half of an ADC sample period (t _(DEVCLK) / 2). This is equivalent to Equation 17. t _O / (2 × D) where
				 t_O is the DDC output sample period D is the decimation factor (17)
				The legal range for this register is 0 to 2D-1. Illegal values result in undefined behavior. Example: When D = 8, the legal register range is 0 to 15. The step size is t_0 / 16 and the maximum delay is 15 x t_0 / 16. Programming this register to 0xFF (the default value) powers down and bypasses the fractional delay filter which reduces the DDC latency by 34 ADC sample periods (as compared to the 0 setting).

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The LM15851 device is a wideband sampling and digital tuning device. The ADC input captures input signals from DC to greater than 3 GHz. The DDC performs digital-down conversion and programmable decimation filtering, and outputs complex (15 bit I and 15 bit Q) data. The resulting output data is output on the JESD204B data interface for capture by the downstream capture or processing device. Most frequency-domain applications benefit from DDC capability to select the desired frequency band and provide only the necessary bandwidth of output data, minimizing the required number of data signals.

8.2 Typical Application

8.2.1 RF Sampling Receiver

An RF Sampling Receiver is used to directly sample a signal in the RF frequency range and provide the data for the captured signal to downstream processing. The wide input bandwidth, high sampling rate, and DDC features of the LM15851 make it ideally suited for this application.

Figure 77. Simplified Schematic

Typical Application (continued)

8.2.1.1 Design Requirements

For this design example, use the parameters listed in Table 81.

Table 81. Design Parameters

DESIGN PARAMETERS	EXAMPLE VALUES					
Signal center frequency	2500 MHz					
Signal bandwidth	100 MHz					
Signal nominal amplitude	–7 dBm					
Signal maximum amplitude	6 dBm					
Minimum SINAD (in bandwidth of interest)	48 dBc					
Minimum SFDR (in bandwidth of interest)	60 dBc					

8.2.1.2 Detailed Design Procedure

Use the following steps to design the RF receiver:

- Use the signal-center frequency and signal bandwidth to select an appropriate sampling rate (DEVCLK frequency) and decimate factor (x / 4 to x / 32).
- Select the sampling rate so that the band of interest is completely within a Nyquist zone.
- Select the sampling rate so that the band of interest is away from any harmonics or interleaving tones.
- Use a frequency planning tool, such as the ADC harmonic calculator (see the <u>Development Support</u> section).
- Select the decimation factor that provides the highest factor possible with an adequate alias-protected output bandwidth to capture the frequency bandwidth of interest.
- Select other system components to provide the needed signal frequency range and DEVCLK rate.
- See Table 1 for recommended balun components.
- Select bandpass filters and limiter components based on the requirement to attenuate unwanted signals
 outside the band of interest (blockers) and to prevent large signals from damaging the ADC inputs. See the
 Absolute Maximum Ratings table.

The LMK048xx JESD204B clocking devices can provide the DEVCLK clock and other system clocks for $f_{(DEVCLK)}$ < 3101 MHz.

For DEVCLK frequencies up to 4 GHz the consider using the LMX2581 and TRF3765 devices as the DEVCLK source. Use the LMK048xx device to provide the JESD204B clocks. For additional device information, see the *Related Documentation* section.

8.2.1.3 Application Curves

The following curve shows an RF signal at 2497.97 MHz captured at a sample rate of 4000 MSPS. Figure 78 shows the spectrum for the output data in decimate-by-32 mode with $f_{\rm (NCO)}$ equal to 2500 MHz. Figure 78 shows the ability to provide only the spectrum of interest in the decimated output data.

8.3 Initialization Set-Up

8.3.1 JESD204B Startup Sequence

The JESD204B interface requires a specific startup and alignment sequence. The general order of that sequence is listed in the following steps.

- 1. Power up or reset the LM15851 device.
- 2. Program JESD_EN = 0 to shut down the link and enable configuration changes.
- 3. Program DECIMATE, SCRAM_EN, KM1 and DDR to the desired settings.
- 4. Configure the device calibration settings as desired, and initiate a calibration (set CAL_SFT = 1).
- 5. Program JESD_EN = 1 to enable the link.
- 6. Apply at least one SYSREF rising edge to establish the LMFC phase.
- 7. Assert SYNC~ from the data receiver to initiate link communications.
- 8. After the JESD204B receiver has established code group synchronization, SYNC~ is de-asserted and the ILA process begins.
- 9. Immediately following the end of the ILA sequence normal data output begins.

NOTE

If deterministic latency is not required this step can be omitted.

8.4 Dos and Don'ts

8.4.1 Common Application Pitfalls

Driving the inputs (analog or digital) beyond the power supply rails. For device reliability, an input must not go more than 150 mV below the ground pins or 150 mV above the supply pins. Exceeding these limits even on a transient basis can cause faulty, or erratic, operation and can impair device reliability. High-speed digital circuits exhibiting undershoot that goes more than a volt below ground is common. To control overshoot, the impedance of high-speed lines must be controlled and these lines must be terminated in the characteristic impedance.

Care must be taken not to overdrive the inputs of the LM15851 device. Such practice can lead to conversion inaccuracies and even to device damage.

Incorrect analog input common-mode voltage in the DC-coupled mode. As described in the *The Analog Inputs* and *DC Coupled Input Usage* sections, the input common-mode voltage (V_{CMI}) must remain the specified range as referenced to the VCMO pin, which has a variability with temperature that must also be tracked. Distortion performance is degraded if the input common mode voltage is outside the specified V_{CMI} range.

Dos and Don'ts (continued)

Using an inadequate amplifier to drive the analog input. Use care when choosing a high frequency amplifier to drive the LM15851 device because many high-speed amplifiers have higher distortion than the LM15851 device which results in overall system performance degradation.

Driving the clock input with an excessively high level signal. The ADC input clock level must not exceed the level described in the *Recommended Operating Conditions* table because the input offset can change if these levels are exceeded.

Inadequate input clock levels. As described in the *Using the Serial Interface* section, insufficient input clock levels can result in poor performance. Excessive input-clock levels can result in the introduction of an input offset.

Using a clock source with excessive jitter, using an excessively long input clock signal trace, or having other signals coupled to the input clock signal trace. These pitfalls cause the sampling interval to vary which causes excessive output noise and a reduction in SNR performance.

Failure to provide adequate heat removal. As described in the *Thermal Management* section, providing adequate heat removal is important to ensure device reliability. Adequate heat removal is primarily provided by properly connecting the thermal pad to the circuit board ground planes. Multiple vias should be arranged in a grid pattern in the area of the thermal pad. These vias will connect the topside pad to the internal ground planes and to a copper pour area on the opposite side of the printed circuit board.

9 Power Supply Recommendations

Data-converter-based systems draw sufficient transient current to corrupt their own power supplies if not adequately bypassed. A $10-\mu F$ capacitor must be placed within one inch (2.5 cm) of the device power pins for each supply voltage. A $0.1-\mu F$ capacitor must be placed as close as possible to each supply pin, preferably within 0.5 cm. Leadless chip capacitors are preferred due to their low-lead inductance.

As is the case with all high-speed converters, the LM15851 device must be assumed to have little power-supply noise-rejection. Any power supply used for digital circuitry in a system where a large amount of digital power is consumed must not be used to supply power to the LM15851 device. If not a dedicated supply, the ADC supplies must be the same supply used for other analog circuitry.

9.1 Supply Voltage

The LM15851 device is specified to operate with nominal supply voltages of 1.9 V (VA19) and 1.2 V (VA12, VD12). For detailed information regarding the operating voltage minimums and maximums see the *Recommended Operating Conditions* table.

During power-up the voltage on all 1.9-V supplies must always be equal to or greater than the voltage on the 1.2-V supplies. Similarly, during power-down, the voltage on the 1.2-V supplies must always be lower than or equal to that of the 1.9-V supplies. In general, supplying all 1.9-V buses from a single regulator, and all 1.2-V buses from a single regulator is the easiest method to ensure that the 1.9-V supplies are greater than the 1.2-V supplies. If the 1.2-V buses are generated from separate regulators, they must rise and fall together (within 200 mV).

The voltage on a pin, including a transient basis, must not have a voltage that is in excess of the supply voltage or below ground by more than 150 mV. A pin voltage that is higher than the supply or that is below ground can be a problem during startup and shutdown of power. Ensure that the supplies to circuits driving any of the input pins, analog or digital, do not rise faster than the voltage at the LM15851 power pins.

The values in the *Absolute Maximum Ratings* table must be strictly observed including during power up and power down. A power supply that produces a voltage spike at power turnon, turnoff, or both can destroy the LM15851 device. Many linear regulators produce output spiking at power on unless there is a minimum load provided. Active devices draw very little current until the supply voltages reach a few hundred millivolts. The result can be a turn-on spike that destroys the LM15851 device, unless a minimum load is provided for the supply. A $100-\Omega$ resistor at the regulator output provides a minimum output current during power up to ensure that no turn-on spiking occurs. Whether a linear or switching regulator is used, TI recommends using a soft-start circuit to prevent overshoot of the supply.

10 Layout

10.1 Layout Guidelines

Proper grounding and proper routing of all signals is essential to ensure accurate conversion. Each ground layer should be a single unified ground plane, rather than splitting the ground planes into analog and digital areas.

Because digital switching transients are composed largely of high frequency components, the skin effect dictates that the total ground-plane copper weight has little effect upon the logic-generated noise. Total surface area is more important than the total ground-plane volume. Coupling between the typically-noisy digital circuitry and the sensitive analog circuitry can lead to poor performance that can be impossible to isolate and remedy. The solution is to keep the analog circuitry well separated from the digital circuitry.

High-power digital components must not be located on or near any linear component or power-supply trace or plane that services analog or mixed-signal components because the resulting common return current path could cause fluctuation in the analog input *ground* return of the ADC which causes excessive noise in the conversion result

In general, assume that analog and digital lines must cross each other at 90° to avoid digital noise into the analog path. In high frequency systems, however, avoid crossing analog and digital lines altogether. The input clock lines must be isolated from **all** other lines, both analog and digital. The generally-accepted 90° crossing must be avoided because even a same amount of coupling causes problems at high frequencies. Best performance at high frequencies is obtained with a straight signal path.

Coupling onto or between the clock and input signal paths must be avoided using any isolation techniques available including distance isolation, orientation planning to prevent field coupling of components like inductors and transformers, and providing well coupled reference planes. Via stitching around the clock signal path and the input analog signal path provides a quiet ground reference for the critical signal paths and reduces noise coupling onto these paths. Sensitive signal traces must not cross other signal traces or power routing on adjacent PCB layers, rather a ground plane must separate the traces. If necessary, the traces should cross at 90° angles to minimize crosstalk.

Isolation of the analog input is important because of the low-level drive required of the LM15851 device. Quality analog input signal and clock signal path layout is required for full dynamic performance. Symmetry of the differential signal paths and discrete components in the path is mandatory and symmetrical shunt-oriented components should have a common grounding via. The high frequency requirements of the input and clock signal paths necessitate using differential routing with controlled impedances and minimizing signal path stubs (including vias) when possible.

Layout of the high-speed serial-data lines is of particular importance. These traces must be routed as tightly coupled $100-\Omega$ differential pairs, with minimal vias. When vias must be used, care must be taken to implement control-impedance vias (that is, $50-\Omega$) with adjacent ground vias for image current control.

10.2 Layout Example

The following examples show layout-example plots (top and bottom layers only). Figure 81 shows a typical stackup for a 10 layer board.

10.3 Thermal Management

The LM15851 device is capable of impressive speeds and performance at low power levels for speed. However, the power consumption is still high enough to require attention to thermal management. The VQFN package has a primary-heat transfer path through the center pad on the bottom of the package. The thermal resistance of this path is provided as R_{BJChot}.

For reliability reasons, the die temperature must be kept to a maximum of 135° C which is the ambient temperature (T_A) plus the ADC power consumption multiplied by the net junction-to-ambient thermal resistance ($R_{\theta JA}$). Maintaining this temperature is not a problem if the ambient temperature is kept to a maximum of 85° C as specified in the *Recommended Operating Conditions* table and the center ground pad on the bottom of the package is thermally connected to a large-enough copper area of the PC board.

The package of the LM15851 device has a center pad that provides the primary heat-removal path as well as excellent electrical grounding to the PCB. Recommended land pattern and solder paste examples are provided in the *Mechanical, Packaging, and Orderable Information* section. The center-pad vias shown must be connected to internal ground planes to remove the maximum amount of heat from the package, as well as to ensure best product parametric performance.

If needed to further reduce junction temperature, TI recommends to build a simple heat sink into the PCB which occurs by including a copper area of about 1 to 2 cm² on the opposite side of the PCB. This copper area can be plated or solder-coated to prevent corrosion, but should not have a conformal coating which would provide thermal insulation. Thermal vias will be used to connect these top and bottom copper areas and internal ground planes. These thermal vias act as *heat pipes* to carry the thermal energy from the device side of the board to the opposite side of the board where the heat can be more effectively dissipated.

11 Device and Documentation Support

11.1 Device Support

11.1.1 Third-Party Products Disclaimer

TI'S PUBLICATION OF INFORMATION REGARDING THIRD-PARTY PRODUCTS OR SERVICES DOES NOT CONSTITUTE AN ENDORSEMENT REGARDING THE SUITABILITY OF SUCH PRODUCTS OR SERVICES OR A WARRANTY, REPRESENTATION OR ENDORSEMENT OF SUCH PRODUCTS OR SERVICES, EITHER ALONE OR IN COMBINATION WITH ANY TI PRODUCT OR SERVICE.

11.1.2 Development Support

For the ADC Harmonic Calculator, got to http://www.ti.com/tool/adc-harmonic-calc.

11.1.3 Device Nomenclature

- **Aperture (sampling) Delay** is the amount of delay, measured from the sampling edge of the clock input, after which the signal present at the input pin is sampled inside the device.
- **Aperture Jitter** $(t_{(AJ)})$ is the variation in aperture delay from sample to sample. Aperture jitter appears as input noise.
- **Clock Duty Cycle** is the ratio of the time that the clock waveform is at a logic high to the total time of one clock period.
- **Full Power Bandwidth (FPBW)** is a measure of the frequency at which the reconstructed output fundamental drops 3 dB below the low frequency value for a full scale input.
- **Interleaving Spurs** are frequency domain (FFT) artifacts resulting from non-idealities in the multi-bank interleaved architecture of the ADC.
 - Offset errors between banks result in fixed spurs at f_S / 4 and f_S / 2. Gain and timing errors result in input-signal-dependent spurs at f_S / 4 ± F_{IN} and f_S / 2 ± F_{IN}.
- Intermodulation Distortion (IMD) is the creation of additional spectral components as a result of two sinusoidal frequencies being applied to the ADC input at the same time. IMD is defined as the ratio of the power in the second-order and third-order intermodulation products to the power in one of the original frequencies. IMD is usually expressed in dBFS.

Device Support (continued)

Least Significant Bit (LSB) is the bit that has the smallest value or weight of all bits. This value is calculated with Equation 18.

V_{FS(dif)} / 2ⁿ

where

- V_{FS(dif)} is the differential full-scale amplitude of V_I as set by the FSR input (pin 14)
- *n* is the ADC resolution in bits, which is 12 for the LM15851 device

(18)

CML Differential Output Voltage (VoD) is the absolute value of the difference between the positive and negative outputs. Each output is measured with respect to Ground.

Figure 82. CML Output Signal Levels

CML Output Offset Voltage (V_{O(ofs)}) is the midpoint between the D+ and D- pins output voltage. Equation 19 is an example of V_{OS} .

$$[(V_D+) + (V_D-)]/2 \tag{19}$$

Most Significant Bit (MSB) is the bit that has the largest value or weight. The value of the MSB is one half of full scale.

Overrange Recovery Time is the time required after the differential input voltages goes from ±1.2 V to 0 V for the converter to recover and make a conversion with its rated accuracy.

Other Spurs is the sum of all higher harmonics (fourth and above), interleaving spurs, and any other fixed or input-dependent spurs.

Data Delay (Latency) is the number of input clock cycles between initiation of conversion and when related data is present at the serializer output.

Spurious-free Dynamic Range (SFDR) is the difference, expressed in dB, between the RMS values of the input signal at the output and the peak spurious signal, where a spurious signal is any signal present in the output spectrum that is not present at the input, excluding DC.

Total Harmonic Distortion (THD) is the ratio expressed in dB, of the RMS total of the first nine harmonic levels at the output to the level of the fundamental at the output. THD is calculated with Equation 20.

THD = 20 x log
$$\sqrt{\frac{A_{f2}^2 + \dots + A_{f10}^2}{A_{f1}^2}}$$

where

Copyright © 2014-2017, Texas Instruments Incorporated

- A_(f1) is the RMS power of the fundamental (output) frequency
- A_(f2) through A_(f10) are the RMS power of the first nine harmonic frequencies in the output spectrum (20)

Second Harmonic Distortion (2nd Harm) is the difference, expressed in dB, between the RMS power in the input frequency detected at the output and the power in the second harmonic level at the output.

Third Harmonic Distortion (3rd Harm) is the difference, expressed in dB, between the RMS power in the input frequency seen at the output and the power in the third harmonic level at the output.

Word Error Rate is the probability of error and is defined as the probable number of errors per unit of time divided by the number of words seen in that amount of time. A Word Error Rate of 10⁻¹⁸ corresponds to a statistical error in one conversion about every four years.

11.2 Documentation Support

11.2.1 Related Documentation

For related documentation see the following:

⁽¹⁾ Status: For more details on status, see our product life cycle.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

⁽²⁾ Material type: When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ RoHS values: Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

⁽⁴⁾ Lead finish/Ball material: Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ MSL rating/Peak reflow: The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ Part marking: There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

PACKAGE OPTION ADDENDUM

VQFN - 0.9 mm max height

PLASTIC QUAD FLATPACK - NO LEAD

NOTES:

- 1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M
- 2. This drawing is subject to change without notice.
- 3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.

PLASTIC QUAD FLATPACK - NO LEAD

NOTES: (continued)

4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/slua271).

PLASTIC QUAD FLATPACK - NO LEAD

NOTES: (continued)

5. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
