

LM317M, LM317MQ Adjustable Floating Regulators

1 Features

- LM317MQ (new chip) AEC-Q100 qualified for automotive applications
 - Temperature grade 2: $-40^{\circ}\text{C} \leq T_A \leq 105^{\circ}\text{C}$
- Adjustable output voltage range (V_{OUT}): 1.25V to 37V
- Output current (I_{OUT}): Up to 500mA
- Built-in, short-circuit current limiting and thermal protection
- Stable without any output capacitor
- Operating junction temperature: -40°C to $+125^{\circ}\text{C}$
- Packages:
 - 4-pin, 6.5mm × 7mm SOT-223 ($R_{\theta\text{JA}}[\text{new chip}] : 77.7^{\circ}\text{C/W}$)
 - 3-pin, 6.6mm × 10.11mm TO-252 ($R_{\theta\text{JA}}[\text{new chip}] : 31.7^{\circ}\text{C/W}$)

2 Applications

- [Cordless vacuum cleaners](#)
- [Building security gateways](#)
- [Multifunction printers](#)
- [Onboard charging](#)

3 Description

The LM317M and LM317MQ are adjustable floating, positive-voltage regulators capable of supplying an output current of 0.5A over an output voltage range of 1.25V to 37V. The device requires only two external resistors to set the output voltage. The device features a typical line regulation of 0.01% and typical load regulation of 0.1%. The device includes current limiting, thermal overload protection, and safe operating area protection.

The device is a floating regulator meaning there is no device ground terminal. Quiescent current flows to the load instead of being wasted flowing to ground. Regulated output voltage of hundreds of volts is possible if the maximum input to output differential does not exceed 37V at any time. The device can function as a floating current source controlled by a single resistor.

Additionally, the device does not need an output capacitor for stable operation across the load current range. Optionally, the transient performance of the device can be improved using an electrolytic or tantalum output capacitor. Bypass the ADJUST pin with any type of capacitor to achieve high ripple-rejection ratios.

Package Information

PART NUMBER	PACKAGE ⁽¹⁾	PACKAGE SIZE ⁽²⁾
LM317M, LM317MQ	DCY (SOT-223, 4)	6.5mm × 7mm
	KVU (TO-252, 3)	6.6mm × 10.11mm

(1) For more information, see the [Mechanical, Packaging, and Orderable Information](#).

(2) The package size (length × width) is a nominal value and includes pins, where applicable.

Table 4-1. Pin Functions

PIN		TYPE	DESCRIPTION
NAME	NO.		
ADJUST	1	I	Output feedback voltage
OUTPUT	2	O	Regulated output voltage. Use the recommended capacitor value as listed in the Recommended Operating Conditions table. Place the output capacitor as close to the OUTPUT and COMMON pins of the device as possible.
INPUT	3	–	Input supply voltage, 2.5V to 37V relative to OUTPUT pin. Use the recommended capacitor value as listed in the Recommended Operating Conditions table. Place the input capacitor as close to the INPUT and COMMON pins of the device as possible.

5 Specifications

5.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
$V_i - V_o$	Input-to-output differential voltage		40	V
T_J	Operating junction temperature		150	°C
T_{stg}	Storage temperature	–65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Rating* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Condition*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

5.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/ JEDEC JS-001, all pins ⁽¹⁾	±2000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101, all pins ⁽²⁾	±1000	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
 (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

5.3 Recommended Operating Conditions

over operating junction temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
$V_I - V_O$	Input-to-output differential voltage	2.5		37	V
V_O	Output voltage	1.25		37	V
I_O	Output current	0.01		0.5	A
C_{IN}	Input capacitor		0.1		μ F
$C_{OUT}^{(1)}$	Output capacitor		0.1		μ F
ESR ⁽¹⁾	Output capacitor	0.01		2	Ω
T_J	Operating junction temperature	-40		125	$^{\circ}$ C

(1) LM317M regulator doesn't need any output capacitor for LDO stability.

5.4 Thermal Information

THERMAL METRIC ⁽¹⁾		LM317M, LM317MQ				UNIT

5.5 Electrical Characteristics (Both Legacy and New Chip)

Over recommended operating virtual-junction temperature range $T_J = -40^\circ\text{C}$ to 125°C , $V_I - V_O = 5\text{V}$, $I_O = 0.1\text{A}$ (unless otherwise noted)

PARAMETER	TEST CONDITIONS		MIN	TYP	MAX	UNIT			
Line regulation	$V_I - V_O = 3\text{V}$ to 40V	$T_J = 25^\circ\text{C}$	Legacy chip and new chip		0.01	0.04	%V		
			Legacy chip and new chip		0.02	0.07			
Load regulation	$I_O = 10\text{mA}$ to 500mA	$T_J = 25^\circ\text{C}$	Legacy chip		0.1	0.5	%		
			New chip		0.1	0.24			
		Legacy chip		0.3	1.5				
		New chip		0.1	0.8				
ADJUST terminal current			Legacy chip		50	100	μA		
			New chip		45	65			
Change in ADJUST terminal current	$V_I - V_O = 3\text{V}$ to 40V , $I_O = 10\text{mA}$ to 500mA		Legacy chip		0.2	5	μA		
	$V_I - V_O = 3\text{V}$ to 15V , $I_O = 10\text{mA}$ to 500mA $V_I - V_O = 15\text{V}$ to 40V , $I_O = 100\text{mA}$		New chip		0.2	5	μA		
Reference voltage	$V_I - V_O = 3\text{V}$ to 40V , $I_O = 10\text{mA}$ to 500mA		Legacy chip		1.2	1.25	1.3	V	
	$V_I - V_O = 3\text{V}$ to 15V , $I_O = 10\text{mA}$ to 500mA $V_I - V_O = 15\text{V}$ to 40V , $I_O = 100\text{mA}$		New chip		1.2	1.25	1.3	V	
Minimum load current to maintain regulation			Legacy chip		3.5	10	mA		
			New chip		1.1	2		3.5	
Output-voltage temperature stability			Legacy chip and new chip		0.7		%		
Maximum output current	$V_I - V_O \leq 15\text{V}$		Legacy chip		500	900	mA		
			New chip		500	1000		1600	
	$V_I - V_O = 40\text{V}$, $\text{PD} \leq \text{PD}(\text{max})$ (1)		$T_J = 25^\circ\text{C}$		Legacy chip			150	250
			$T_J = 25^\circ\text{C}$		New chip			110	220
RMS output noise voltage (% of V_O)	$f = 10\text{Hz}$ to 10kHz ,	$T_J = 25^\circ\text{C}$	Legacy chip and new chip		0.003		% V_O		
Long-term stability			$T_J = 25^\circ\text{C}$		Legacy chip		0.3	1	%/1k hrs
	$I_O = 10\text{mA}$		$T_J = 25^\circ\text{C}$		New chip		0.3	1	
Ripple rejection	$V_O = 10\text{V}$, $f = 120\text{Hz}$, $C_{\text{ADJ}} = 0$		$T_J = 25^\circ\text{C}$		Legacy chip		65	dB	
			$T_J = 25^\circ\text{C}$		New chip		65		
	$V_O = 10\text{V}$, $f = 120\text{Hz}$, $C_{\text{ADJ}} = 10\mu\text{F}$		$T_J = 25^\circ\text{C}$		Legacy chip		66		80
			$T_J = 25^\circ\text{C}$		New chip		66		80

(1) Maximum power dissipation is a function of T_J (max), θ_{JA} , and T_A . The maximum allowable power dissipation at any allowable ambient temperature is $\text{PD} = (T_J(\text{max}) - T_A) / \theta_{\text{JA}}$. Operating at the absolute maximum T_J of 150°C can affect reliability.

5.6 Typical Characteristics

Over recommended operating virtual-junction temperature range $T_J = -40^{\circ}\text{C}$ to 125°C , $V_I - V_O = 5\text{V}$, $I_O = 0.1\text{A}$ (unless otherwise noted)

6 Detailed Description

6.1 Overview

The LM317M and LM317MQ is an adjustable floating, positive-voltage regulator capable of supplying up to 500mA over an output voltage range of 1.25V to 37V. The device has a feedback voltage relative to the output instead of ground. The device requires only two external resistors to set the output voltage. The LM317MQ includes current limiting, thermal overload protection, and safe operating area protection. Overload protection remains functional even if the ADJUST pin is disconnected. By connecting a fixed resistor between the ADJUST and OUTPUT pins, the device can function as a precision current regulator. Add an optional output capacitor to improve transient response. Bypass the ADJUST pin to achieve very high ripple-rejection ratios, which are difficult to achieve with standard three-terminal regulators.

6.2 Functional Block Diagram

6.3 Feature Description

6.3.1 Current Limit

The device has an internal current-limit circuit that protects the regulator during transient high-load current faults or shorting events. In a high-load current fault, the current limit scheme limits the output current to the current limit (I_{CL}). I_{CL} is listed in the [Electrical Characteristics \(Both Legacy and New Chip\)](#) table.

The output voltage is not regulated when the device is in current limit. When a current-limit event occurs, the device begins to heat up because of the increase in power dissipation. When the device is in current limit, the pass transistor dissipates power $[(V_I - V_O) \times I_{CL}]$. For more information on current limits, see the [Know Your Limits](#) application note.

To achieve a safe operation across a wide range of Input voltage, the device also has a built-in protection mechanism with current limit. The protection mechanism decreases the current limit as input-to-output voltage increases and keeps the power transistor inside a safe operating region for all values of input-to-output voltage. This protection is designed to provide some output current at all values of input-to-output voltage limits defined in the [Recommended Operating Conditions](#) table. [Figure 6-1](#) illustrates the behavior of the current limit variation.

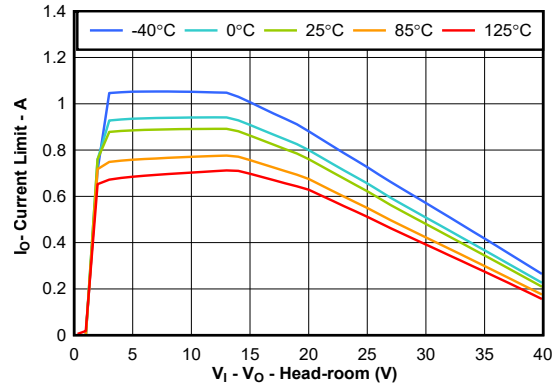

Figure 6-1. Current-Limit vs $V_{\text{Head-room}}$ Behavior (New Chip)

6.3.2 Dropout Voltage (V_{DO})

Dropout voltage (V_{DO}) is defined as the input voltage minus the output voltage ($V_I - V_O$) at the rated output current (I_{RATED}), where the pass transistor is fully on. I_{RATED} is the maximum I_O listed in the [Recommended Operating Conditions](#) table. In dropout operation, the pass transistor is in the ohmic or triode region of operation, and acts as a switch. The dropout voltage indirectly specifies a minimum input voltage greater than the nominal programmed output voltage at which the output voltage is expected to stay in regulation. If the input voltage falls to less than the value required to maintain output regulation, then the output voltage falls as well.

6.3.3 Thermal Shutdown

The device contains a thermal shutdown protection circuit to disable the device when the junction temperature (T_J) of the pass transistor rises to $T_{SD(\text{shutdown})}$ (typical). Thermal shutdown hysteresis makes sure that the device resets (turns on) when the temperature falls to $T_{SD(\text{reset})}$ (typical).

The thermal time-constant of the semiconductor die is fairly short, thus the device cycles on and off when thermal shutdown is reached until power dissipation is reduced. Power dissipation during start-up is high from large $V_I - V_O$ voltage drops across the device or from high inrush currents charging large output capacitors. Under some conditions, the thermal shutdown protection disables the device before start-up completes.

For reliable operation, limit the junction temperature to the maximum listed in the [Recommended Operating Conditions](#) table. Operation above this maximum temperature causes the device to exceed operational specifications. Although the internal protection circuitry of the device is designed to protect against thermal overall conditions, this circuitry is not intended to replace proper heat sinking. Continuously running the device into thermal shutdown or above the maximum recommended junction temperature reduces long-term reliability.

6.4 Device Functional Modes

6.4.1 Normal Operation

The device OUTPUT pin regulates to 1.25V greater than the ADJUST pin under the following conditions:

- The input voltage is greater than the nominal output voltage plus the dropout voltage ($V_{OUT(NOM)} + V_{DO}$).
- The output current is less than the current limit ($I_O < I_{CL}$).
- The device passes the bias current to the OUTPUT pin. The load or feedback consumes this minimum current for regulation.
- The device junction temperature is greater than -40°C and less than $+125^{\circ}\text{C}$.

6.4.2 Dropout Operation

If the input voltage is lower than the nominal output voltage plus the specified dropout voltage, but all other conditions are met for normal operation, the device operates in dropout mode. In this mode, the output voltage tracks the input voltage. During this mode, the transient performance of the device becomes significantly degraded because the pass transistor is in the ohmic or triode region, and acts as a switch. Line or load transients in dropout potentially result in large output voltage deviations.

When the device is in a steady dropout state (defined as when the device is in dropout, $V_I < V_{OUT(NOM)} + V_{DO}$, directly after being in a normal regulation state, but *not* during start up), the pass transistor is driven into the ohmic or triode region. When the input voltage returns to a value greater than or equal to the nominal output voltage plus the dropout voltage ($V_{OUT(NOM)} + V_{DO}$), the output voltage overshoots for a short period of time while the device pulls the pass transistor back into the linear region.

7 Applications and Implementation

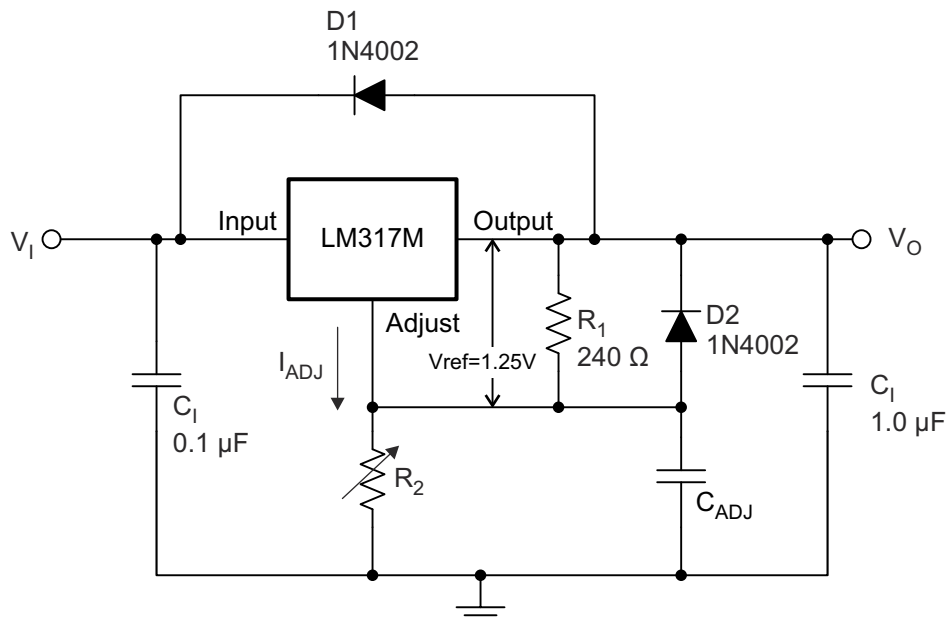

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

7.1 Application Information

The LM317M and LM317MQ are linear voltage regulators. The feedback is the output pin to adjust pin differential. Set the output voltage to any value from 1.25V to V_O maximum with two resistors.

7.2 Typical Application

7.2.1 Design Requirements

For this design example, use the parameters listed in [Table 7-1](#).

Table 7-1. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
Input voltage range	(Output voltage + 2.5V) to 37V
Output voltage	$V_{ref} \times (1 + R2 / R1) + I_{adj} \times R2$

7.2.2 Detailed Design Procedure

7.2.2.1 Input and Output Capacitor Requirements (Legacy Chip)

An input capacitor is not required, but is recommended, particularly if the regulator is not in close proximity to the power-supply filter capacitors. A 0.1μF ceramic or 1μF tantalum capacitor provides sufficient bypassing for most applications, especially when adjustment and output capacitors are used. An output capacitor improves transient response, but is not needed for stability.

7.2.2.2 Input and Output Capacitor Requirements (New Chip)

Although the input and output capacitors are not required for stability, good analog design practice is to connect a capacitor from INPUT to ground and from OUTPUT to ground. The input capacitor counteracts reactive input sources and improves transient response, input ripple, and PSRR. Use an input capacitor if the source

impedance is more than 0.5Ω. A higher value capacitor is necessary if large, fast rise-time load or line transients are anticipated or if the device is located several inches from the input power source.

Dynamic performance of the device is improved by using a large output capacitor. Use an output capacitor within the range specified in the [Recommended Operating Conditions](#) table for stability.

7.2.2.3 Feedback Resistors

The feedback resistor sets the output voltage using the following equation.

$$V_{\text{ref}} \times (1 + R2/R1) + I_{\text{adj}} \times R2 \quad (1)$$

7.2.2.4 Adjustment Pin Capacitor

The optional adjustment pin capacitor improves ripple rejection by preventing the amplification of the ripple. When the capacitor is used and $V_{\text{OUT}} > 6\text{V}$, a protection diode from adjust to output is recommended.

7.2.2.5 Protection Diodes

If the input is shorted to ground during a fault condition, protection diode (D1) prevents discharge through the device. If the output is shorted to ground during a fault condition, protection diode (D2) prevents adjust pin capacitor discharge through the device.

7.2.2.6 Overload Recovery

Because the input voltage rises when power is first turned on, the output follows the input, allowing the regulator to start up into very heavy loads. The input-to-output voltage differential is small during start up when the input voltage is rising, allowing the regulator to supply large output currents. With a high input voltage, a problem occurs where removing an output short does not allow the output voltage to recover. Other regulators also exhibit this phenomenon, so the behavior is not unique to the LM317M and LM317MQ.

The problem occurs with a heavy output load when the input voltage is high and the output voltage is low. Common situations occur immediately when removing a short circuit after the input voltage is already turned on. The load line for such a load has the possibility to intersect the output current curve at two points. If this condition happens, there are two stable output operating points for the regulator. With this double intersection, the input power supply is potentially cycled down to zero and brought up again to make the output recover to the desired voltage operating point.

7.2.2.7 Estimating Junction Temperature

The JEDEC standard now recommends the use of psi (Ψ) thermal metrics to estimate the junction temperatures of the linear regulator when in circuit on a typical PCB board application. These metrics are not thermal resistance parameters and instead offer a practical and relative way to estimate junction temperature. These psi metrics are determined to be significantly independent of the copper area available for heat-spreading. The [Thermal Information](#) table lists the primary thermal metrics, which are the junction-to-top characterization parameter (ψ_{JT}) and junction-to-board characterization parameter (ψ_{JB}). These parameters provide two methods for calculating the junction temperature (T_{J}), as described in the following equations. Use the junction-to-top characterization parameter (ψ_{JT}) with the temperature at the center-top of device package (T_{T}) to calculate the junction temperature. Use the junction-to-board characterization parameter (ψ_{JB}) with the PCB surface temperature 1mm from the device package (T_{B}) to calculate the junction temperature.

$$T_{\text{J}} = T_{\text{T}} + \psi_{\text{JT}} \times P_{\text{D}} \quad (2)$$

where:

- P_{D} is the dissipated power
- T_{T} is the temperature at the center-top of the device package

$$T_{\text{J}} = T_{\text{B}} + \psi_{\text{JB}} \times P_{\text{D}} \quad (3)$$

where:

- T_B is the PCB surface temperature measured 1mm from the device package and centered on the package edge

For detailed information on the thermal metrics and how to use them, see the [Semiconductor and IC Package Thermal Metrics application note](#).

7.2.2.8 Polarity Reversal Protection

In many applications, a voltage regulator powers a load that is not connected to ground, but instead, is connected to a voltage source of the opposite polarity (for example, operational amplifiers, level-shifting circuits, and so on). During start-up and short-circuit events, this connection leads to polarity reversal of the regulator output and damages the internal components of the regulator.

To avoid polarity reversal on the regulator output, use external protection to protect the device.

Figure 7-1 shows one approach for protecting the device.

Figure 7-1. Example Circuit for Polarity Reversal Protection Using a Schottky Diode

7.2.2.9 Reverse Current

Excessive reverse current damages this device. Reverse current flows through the emitter-base junction of the pass transistor instead of the normal conducting channel. At high magnitudes, this current flow degrades the long-term reliability of the device.

Conditions where reverse current occur are outlined in this section, all of which exceed the absolute maximum rating of $V_O \leq V_I + 7V$. These conditions are:

- If the device has a large C_{OUT} and the input supply collapses with little or no load current
- The output is biased when the input supply is not established
- The output is biased above the input supply

If reverse current flow is expected in the application, use external protection to protect the device. Reverse current is not limited in the device, so external limiting is required if extended reverse voltage operation is anticipated. Limit reverse current to 5% or less of the rated output current of the device in the event this current cannot be avoided.

Figure 7-2 shows one approach for protecting the device.

Figure 7-2. Example Circuit for Reverse Current Protection Using a Schottky Diode

7.2.2.10 Power Dissipation (P_D)

Circuit reliability requires consideration of the device power dissipation, location of the circuit on the printed circuit board (PCB), and correct sizing of the thermal plane. Make sure the PCB area around the regulator has few or no other heat-generating devices that cause added thermal stress.

To first-order approximation, power dissipation in the regulator depends on the input-to-output voltage difference and load conditions. The following equation calculates power dissipation (P_D).

$$P_D = (V_I - V_O) \times I_O \quad (4)$$

Note

Power dissipation is minimized, and therefore greater efficiency be achieved, by correct selection of the system voltage rails. For the lowest power dissipation, use the minimum input voltage required for correct output regulation.

For devices with a thermal pad, the primary heat conduction path for the device package is through the thermal pad to the PCB. Solder the thermal pad to a copper pad area under the device. This pad area contains an array of plated vias that conduct heat to additional copper planes for increased heat dissipation.

The maximum power dissipation determines the maximum allowable ambient temperature (T_A) for the device. According to the following equation, power dissipation and junction temperature are most often related by the junction-to-ambient thermal resistance ($R_{\theta JA}$) of the combined PCB and device package and the temperature of the ambient air (T_A).

$$T_J = T_A + (R_{\theta JA} \times P_D) \quad (5)$$

Thermal resistance ($R_{\theta JA}$) is highly dependent on the heat-spreading capability built into the particular PCB design, and therefore varies according to the total copper area, copper weight, and location of the planes. The junction-to-ambient thermal resistance listed in the [Thermal Information](#) table is determined by the JEDEC standard PCB and copper-spreading area, and is used as a relative measure of package thermal performance. As mentioned in the [An empirical analysis of the impact of board layout on LDO thermal performance application note](#), $R_{\theta JA}$ is improved by 35% to 55% compared to the [Thermal Information](#) table value with the PCB board layout optimization.

7.2.3 Application Curves

Figure 7-3. Line Transient Response vs Time (Legacy Chip)

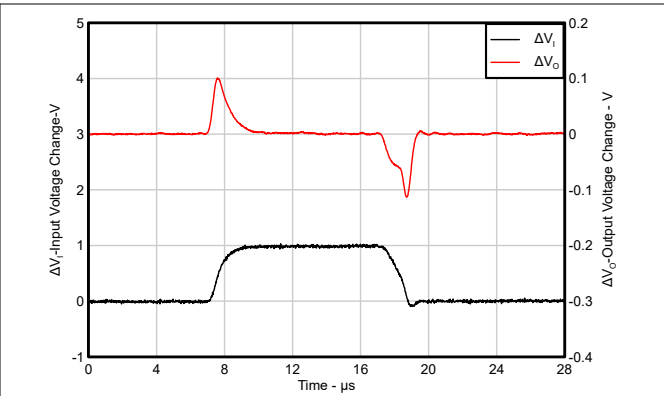

Figure 7-4. Line Transient Response vs Time (New Chip)

Figure 7-5. Load Transient Response vs Time (Legacy Chip)

Figure 7-6. Load Transient Response vs Time (New Chip)

Figure 7-7. Load Transient Response vs Time (New Chip)

7.3 Power Supply Recommendations

Keep trace widths large enough to eliminate problematic $I \times R$ voltage drops at the input and output pins. Place bypass capacitors as close to the device as possible. Additional copper and vias connected to ground facilitate additional thermal dissipation, preventing the device from reaching thermal overload.

7.4 Layout

7.4.1 Layout Guidelines

- Bypass the input pin to ground with a bypass capacitor.
- The optimum placement is closest to the VIN and GND pins of the device. Make sure to minimize the loop area formed by the bypass capacitor connection, the VIN pin, and the GND pin of the device.
- For operation at full-rated load, use wide trace lengths to eliminate IR drop and heat dissipation.

7.4.2 Layout Example

Table 8-1. Available Options

PRODUCT ⁽¹⁾	DESCRIPTION
LM317MQyyyz LM317MQDCYz M3Q1	<p>Q indicates that the device is a grade-1 device in accordance with the AEC-Q100 standard.</p> <p>yyy is the package designator.</p> <p>z is the package quantity.</p> <p>Devices either ship with the legacy chip (CSO: SFB) or the new chip (CSO: RFB). The reel packaging label provides CSO information to distinguish which chip is used. Device performance for new and legacy chips is denoted throughout the document. M3 is a suffix designator only significant for the new chip with CSO:RFB, which uses the latest manufacturing flow</p>

(1) For the most current package and ordering information see the Package Option Addendum at the end of this document, or see the TI website at [www.ti.com](#).

8.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on [ti.com](#). Click on *Notifications* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

8.3 Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

8.4 Trademarks

TI E2E™ is a trademark of Texas Instruments.
All trademarks are the property of their respective owners.

8.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

8.6 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

9 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision Q (July 2025) to Revision R (April 2026)	Page
• Added details about AEC-Q100 qualification for LM317MQ in Features section.....	1
• Updated <i>Description</i> section for better readability and corrected pin-count for SOT-223 package.....	1
• Corrected maximum input to output differential from 40V to 37V.....	1
• Corrected maximum input to output differential from 40V to 37V.....	3
• Corrected pin-count for SOT-223 (DCY) package.....	4
• Added test conditions used to capture typical characterisitcs plots.....	6
• Updated <i>Overview</i> section for better readability.....	10
• Added details about M3 devices in <i>Device Nomenclature</i> section.....	19

Changes from Revision P (February 2014) to Revision Q (July 2025)	Page
• Updated the numbering format for tables, figures, and cross-references throughout the document.....	1
• Deleted KTP package and information from document.....	1
• Changed entire document to align with current family format.....	1
• Added new silicon (M3) devices to document.....	1
• Added new silicon curves to <i>Typical Characteristics</i> section	1
• Added <i>Current Limit</i> section.....	10
• Changed <i>LM317M</i> to <i>LM317M and LM317MQ</i> in <i>Protection Diodes</i> section.....	14
• Changed <i>Power Supply Recommendations</i> section.....	18
• Added <i>Device Nomenclature</i> section.....	19

10 Mechanical, Packaging, and Orderable Information

The following pages include mechanical packaging and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATASHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you fully indemnify TI and its representatives against any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to [TI's Terms of Sale](#), [TI's General Quality Guidelines](#), or other applicable terms available either on [ti.com](#) or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products. Unless TI explicitly designates a product as custom or customer-specified, TI products are standard, catalog, general purpose devices.

TI objects to and rejects any additional or different terms you may propose.
