

LM5025 Active Clamp Voltage Mode PWM Controller

1 Features

- Internal Start-Up Bias Regulator
- 3-A Compound Main Gate Driver
- Programmable Line Undervoltage Lockout (UVLO) With Adjustable Hysteresis
- Voltage Mode Control With Feed-Forward
- Adjustable Dual-Mode Overcurrent Protection
- Programmable Overlap or Deadtime Between the Main and Active Clamp Outputs
- Volt × Second Clamp
- Programmable Soft-Start
- Leading Edge Blanking
- Single Resistor Programmable Oscillator
- Oscillator UP and DOWN Sync Capability
- Precision 5-V Reference
- Thermal Shutdown

2 Applications

- Server Power Supplies
- 48-V Telecom Power Supplies
- 42-V Automotive Applications
- High-Efficiency DC-to-DC Power Supplies

3 Description

The LM5025 PWM controller contains all of the features necessary to implement power converters using the active clamp and reset technique. The device can be configured to control either a P-channel clamp switch or an N-channel clamp switch. With the active clamp technique, higher efficiencies and greater power densities can be realized compared to conventional catch winding or RDC clamp and reset techniques.

Two control outputs are provided, the main power switch control (OUT_A), and the active clamp switch control (OUT_B). The active clamp output can be configured for either a specified overlap time (for P-channel switch applications) or a specified deadtime (for N-channel applications). The two internal compound gate drivers parallel both MOS and bipolar devices, providing superior gate drive characteristics. This controller is designed for high-speed operation including an oscillator frequency range up to 1 MHz and total PWM and current sense propagation delays less than 100 ns.

The LM5025 includes a high-voltage start-up regulator that operates over a wide input range of 13 V to 90 V. Additional features include: line undervoltage lockout (UVLO), soft-start, oscillator UP and DOWN sync capability, precision reference and thermal shutdown.

Pin Functions

PIN		I/O ⁽¹⁾	DESCRIPTION	APPLICATION INFORMATION
NO.	NAME			
1	V _{IN}	I	Source input voltage	Input to start-up regulator. Input 13 V to 90 V, with transient capability to 100 V.
2	RAMP	I	Modulator ramp signal	An external RC circuit from Vin sets the ramp slope. This pin is discharged at the conclusion of every cycle by an internal FET, initiated by either the internal clock or the V*Sec Clamp comparator.
3	CS1	I	Current sense input for cycle-by-cycle limiting	If CS1 exceeds 0.25 V the outputs goes into Cycle-by-Cycle current limit. CS1 is held low for 50 ns after OUT_A switches high providing leading edge blanking.
4	CS2	I	Current sense input for soft restart	If CS2 exceeds 0.25 V the outputs are disabled and a soft-start commences. The soft-start capacitor is fully discharged and then released with a pullup current of 1 µA. After the first output pulse (when SS = 1 V), the SS charge current reverts back to 20 µA. CS2 is held low for 50 ns after OUT_A switches high, providing leading edge blanking.
5	TIME	I	Output overlap and deadtime control	An external resistor (R _{SET}) sets either the overlap time or dead time for the active clamp output. An R _{SET} resistor connected between TIME and GND produces in-phase OUT_A and OUT_B pulses with overlap. An R _{SET} resistor connected between TIME and REF produces out-of-phase OUT_A and OUT_B pulses with deadtime.
6	REF	O	Precision 5-V reference output	Maximum output current: 10-mA locally decouple with a 0.1-µF capacitor. Reference stays low until the line UVLO and the V _{CC} UV comparators are satisfied.
7	V _{CC}	P	Output from the internal high-voltage start-up regulator. The V _{CC} voltage is regulated to 7.6 V	If an auxiliary winding raises the voltage on this pin above the regulation setpoint, the internal start-up regulator shutdowns, reducing the IC power dissipation.
8	OUT_A	O	Main output driver	Output of the main switch PWM output gate driver. Output capability of 3-A peak sink current.
9	OUT_B	O	Active clamp output driver	Output of the active clamp switch gate driver. Capable of 1.25-A peak sink current..
10	PGND	G	Power ground	Connect directly to analog ground.
11	AGND	G	Analog ground	Connect directly to power ground. For the WSON package option the exposed pad is electrically connected to AGND.
12	SS	I	Soft-start control	An external capacitor and an internal 20-µA current source set the soft-start ramp. The SS current source is reduced to 1 µA initially following a CS2 overcurrent event or an over temperature event.

(1) P = power, G = ground, I = input, O = Output, I/O = Input/output

Pin Functions (continued)

PIN		I/O ⁽¹⁾	DESCRIPTION	APPLICATION INFORMATION
NO.	NAME			
13	COMP	I	Input to the pulse width modulator	An internal 5-K Ω resistor pullup is provided on this pin. The external opto-coupler sinks current from COMP to control the PWM duty cycle.
14	RT	I	Oscillator timing resistor pin	An external resistor connected from RT to ground sets the internal oscillator frequency.
15	SYNC	I	Oscillator UP and DOWN synchronization input	The internal oscillator can be synchronized to an external clock with a frequency 20% lower than the internal oscillator's free running frequency. There is no constraint on the maximum sync frequency.
16	UVLO	I	Line undervoltage shutdown	An external voltage divider from the power source sets the shutdown comparator levels. The comparator threshold is 2.5 V. Hysteresis is set by an internal current source (20 μ A) that is switched on or off as the UVLO pin potential crosses the 2.5-V threshold.

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
Input voltage	V _{IN} to GND	–0.3	100	V
	V _{CC} to GND	–0.3	16	
CS1, CS2 to GND		–0.3	1	V
All other inputs to GND		–0.3	7	V
Junction temperature, T _J			150	°C
Storage temperature, T _{stg}		–55	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

6.2 ESD Ratings

		VALUE	UNIT
V _(ESD) Electrostatic discharge ⁽¹⁾	Human-body model (HBM), per ANSI/ESDA/JEDEC JS01 ⁽²⁾	±2000	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽³⁾	±500	

- (1) For detailed information on soldering plastic TSSOP and WSON packages, refer to the Packaging Data Book.
 (2) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
 (3) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

	MIN	NOM	MAX	UNIT
V _{IN} voltage	13		90	V
External voltage applied to V _{CC}	8		15	V
Operating junction temperature	–40		125	°C

7 Detailed Description

7.1 Overview

The LM5025 PWM controller contains all of the features necessary to implement power converters using the active clamp reset technique. The device can be configured to control either a P-channel clamp switch or an N-channel clamp switch. With the active clamp technique higher efficiencies and greater power densities can be realized compared to conventional catch winding or RDC clamp and reset techniques. Two control outputs are provided, the main power switch control (OUT_A), and the active clamp switch control (OUT_B). The active clamp output can be configured for either a specified overlap time (for P-channel switch applications) or a specified dead time (for N_channel applications). The two internal compound gate drivers parallel both MOS and bipolar devices, providing superior gate-drive characteristics. This controller is designed for high-speed operation including an oscillator frequency range up to 1 MHz and total PWM and current sense propagation delays less than 100 ns. The LM5025 includes a high-voltage start-up regulator that operates over a wide input of 13 V to 90 V. Additional features include: line undervoltage lockout (UVLO), soft-start, oscillator UP and DOWN sync capability, precision reference and thermal shutdown.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 High-Voltage Start-Up Regulator

The LM5025 contains an internal high-voltage start-up regulator that allows the input pin (V_{IN}) to be connected directly to the line voltage. The regulator output is internally current limited to 20 mA. When power is applied, the regulator is enabled and sources current into an external capacitor connected to the V_{CC} pin. The recommended capacitance for the V_{CC} regulator is 0.1 μ F to 100 μ F. When the voltage on the V_{CC} pin reaches the regulation point of 7.6 V and the internal voltage reference (REF) reaches its regulation point of 5 V, the controller outputs are enabled. The outputs remain enabled until V_{CC} falls below 6.2 V or the line undervoltage lock out detector indicates that V_{IN} is out of range. In typical applications, an auxiliary transformer winding is connected through a diode to the V_{CC} pin. This winding must raise the V_{CC} voltage above 8 V to shut off the internal start-up regulator. Powering V_{CC} from an auxiliary winding improves efficiency while reducing the controller power dissipation.

The external V_{CC} capacitor must be sized such that the capacitor and V_{CC} self-bias maintains a V_{CC} voltage greater than 6.2 V during the initial start-up. During a fault mode when the converter auxiliary winding is inactive, external current draw on the V_{CC} line must be limited so the power dissipated in the start-up regulator does not exceed the maximum power dissipation of the controller.

An external start-up regulator or other bias rail can be used instead of the internal start-up regulator by connecting the V_{CC} and the V_{IN} pins together and feeding the external bias voltage into the two pins.

7.3.2 Line Undervoltage Detector

The LM5025 contains a line undervoltage lock out (UVLO) circuit. An external set-point voltage divider from V_{in} to GND, sets the operational range of the converter. The divider must be designed such that the voltage at the UVLO pin is greater than 2.5 V when V_{in} is in the desired operating range. If the undervoltage threshold is not met, all functions of the controller are disabled and the controller remains in a low-power standby state. UVLO hysteresis is accomplished with an internal 20- μ A current source that is switched on or off into the impedance of the set-point divider. When the UVLO threshold is exceeded, the current source is activated to instantly raise the voltage at the UVLO pin. When the UVLO pin voltage falls below the 2.5-V threshold, the current source is turned off, causing the voltage at the UVLO pin to fall. The UVLO pin can also be used to implement a remote enable and disable function. Pulling the UVLO pin below the 2.5-V threshold disables the converter.

7.3.3 PWM Outputs

The relative phase of the main (OUT_A) and active clamp outputs (OUT_B) can be configured for the specific application. For active clamp configurations using a ground referenced P-channel clamp switch, the two outputs must be in phase with the active clamp output overlapping the main output. For active clamp configurations using a high side N-channel switch, the active clamp output must be out of phase with main output and there must be a dead time between the two gate drive pulses. A distinguishing feature of the LM5025 is the ability to accurately configure either dead time (both off) or overlap time (both on) of the gate driver outputs. The overlap and deadtime magnitude is controlled by the resistor value connected to the TIME pin of the controller. The opposite end of the resistor can be connected to either REF for deadtime control or GND for overlap control. The internal configuration detector senses the connection and configures the phase relationship of the main and active clamp outputs.

7.3.4 Compound Gate Drivers

The LM5025 contains two unique compound gate drivers, which parallel both MOS and bipolar devices to provide high-drive current throughout the entire switching event. The bipolar device provides most of the drive current capability and provides a relatively constant sink current that is ideal for driving large power MOSFETs. As the switching event nears conclusion and the bipolar device saturates, the internal MOS device continues to provide a low-impedance to complete the switching event.

During turnoff at the Miller plateau region, typically around 2 V to 3 V, is where gate driver current capability is needed most. The resistive characteristics of all MOS gate drivers are adequate for turnon, because the supply to output voltage differential is fairly large at the Miller region. During turnoff however, the voltage differential is small and the current source characteristic of the bipolar gate driver is beneficial to provide fast drive capability.

Feature Description (continued)

Figure 10. Compound Gate Drivers

7.3.5 PWM Comparator

The PWM comparator compares the ramp signal (RAMP) to the loop error signal (COMP). This comparator is optimized for speed to achieve minimum controllable duty cycles. The internal 5-k Ω pullup resistor, connected between the internal 5-V reference and COMP can be used as the pullup for an optocoupler. The comparator polarity is such that 0 V on the COMP pin produces a zero-duty cycle on both gate driver outputs.

7.3.6 Volt Second Clamp

The volt $\times$ second clamp comparator compares the ramp signal (RAMP) to a fixed 2.5-V reference. By proper selection of RFF and CFF, the maximum ON time of the main switch can be set to the desired duration. The ON time set by volt $\times$ second clamp varies inversely with the line voltage because the RAMP capacitor is charged by a resistor connected to Vin while the threshold of the clamp is a fixed voltage (2.5 V).

The C_{FF} ramp capacitor is discharged at the conclusion of every cycle by an internal discharge switch controlled by either the internal clock or by the V $\times$ S Clamp comparator, whichever event occurs first.

7.3.7 Current Limit

The LM5025 contains two modes of overcurrent protection. If the sense voltage at the CS1 input exceeds 0.25 V the present power cycle is terminated (cycle-by-cycle current limit). If the sense voltage at the CS2 input exceeds 0.25 V, the controller terminates the present cycle, discharge the soft-start capacitor and reduce the soft-start current source to 1 μ A. The soft-start (SS) capacitor is released after being fully discharged and slowly charges with a 1- μ A current source. When the voltage at the SS pin reaches approximately 1 V, the PWM comparator produces the first output pulse at OUT_A. After the first pulse occurs, the soft-start current source reverts to the normal 20- μ A level. Fully discharging and then slowly charging the SS capacitor protects a continuously overloaded converter with a low-duty cycle hiccup mode.

These two modes of overcurrent protection allows the user great flexibility to configure the system behavior in overload conditions. If it is desired for the system to act as a current source during an overload, then the CS1 cycle-by-cycle current limiting must be used. In this case the current sense signal must be applied to the CS1 input and the CS2 input must be grounded. If during an overload condition it is desired for the system to briefly shutdown, followed by soft-start retry, then the CS2 hiccup current limiting mode must be used. In this case the current sense signal must be applied to the CS2 input and the CS1 input must be grounded. This shutdown and soft-start retry repeats indefinitely while the overload condition remains. The hiccup mode greatly reduces the thermal stresses to the system during heavy overloads. The cycle-by-cycle mode has higher system thermal dissipations during heavy overloads, but provides the advantage of continuous operation for short duration overload conditions.

Feature Description (continued)

In some systems it is possible use both modes concurrently, whereby slight overload conditions activate the CS1 cycle-by cycle mode, while more severe overloading activates the CS2 hiccup mode. Operating both modes concurrently requires that the slope of the inductor current be sufficient to reach the CS2 threshold before the CS1 function turns off the main output switch. This requires a high dv/dt at the current sense pin. The signal must be fast enough to reach the second-level threshold before the first threshold detector (CS1) turns off the gate driver. Excessive filtering on the CS pin, an extremely low-value current sense resistor or an inductor that does not saturate with excessive loading may prevent the second-level threshold from ever being reached.

TI recommends a small RC filter, located near the controller, for each of the CS pins. Each CS input has an internal FET that discharges the current sense filter capacitor at the conclusion of every cycle, to improve dynamic performance. This same FET remains on an additional 50 ns at the start of each main switch cycle to attenuate the leading edge spike in the current sense signal.

The LM5025 CS comparators are very fast and may respond to short duration noise pulses. Layout considerations are critical for the current sense filter and sense resistor. The capacitor associated with the CS filter must be placed very close to the device and connected directly to the pins of the IC (CS and GND). If a current sense transformer is used, both leads of the transformer secondary must be routed to the filter network, which must be located close to the IC. If a sense resistor in the source of the main switch MOSFET is used for current sensing, a low-inductance type of resistor is required. When designing with a current sense resistor, all of the noise sensitive low-power ground connections must be connected together near the IC GND and a single connection must be made to the power ground (sense resistor ground point).

Figure 11. Current Limit

7.3.8 Oscillator and Sync Capability

The LM5025 oscillator is set by a single external resistor connected between the RT pin and GND.

The RT resistor must be located very close to the device and connected directly to the pins of the IC (RT and GND).

A unique feature of LM5025 is the ability to synchronize the oscillator to an external clock with a frequency that is either higher or lower than the frequency of the internal oscillator. The lower frequency sync frequency range is 80% of the free running internal oscillator frequency. There is no constraint on the maximum SYNC frequency. A minimum pulse width of 100 ns is required for the synchronization clock. If the synchronization feature is not required, the SYNC pin must be connected to GND to prevent any abnormal interference. The internal oscillator can be completely disabled by connecting the RT pin to REF. Once disabled, the sync signal acts directly as the master clock for the controller. Both the frequency and the maximum duty cycle of the PWM controller can be controlled by the SYNC signal (within the limitations of the volt × second clamp). The maximum duty cycle (D) is (1D) of the SYNC signal.

Feature Description (continued)

7.3.9 Feed-Forward Ramp

An external resistor (R_{FF}) and capacitor (C_{FF}) connected to V_{IN} and GND are required to create the PWM ramp signal. The slope of the signal at the RAMP pin varies in proportion to the input line voltage. This varying slope provides line feedforward information necessary to improve line transient response with voltage mode control. The RAMP signal is compared to the error signal at the COMP pin by the pulse width modulator comparator to control the duty cycle of the main switch output. The volt second clamp comparator also monitors the RAMP pin and if the ramp amplitude exceeds 2.5 V the present cycle is terminated. The ramp signal is reset to GND at the end of each cycle by either the internal clock or the volt second comparator, whichever occurs first.

7.3.10 Soft-Start

The soft-start feature allows the power converter to gradually reach the initial steady state operating point, thus reducing start-up stresses and surges. At power on, a 20- μ A current is sourced out of the soft-start pin (SS) into an external capacitor. The capacitor voltage ramps up slowly and limits the COMP pin voltage and therefore the PWM duty cycle. In the event of a fault as determined by V_{CC} undervoltage, line undervoltage (UVLO), or second-level current limit, the output gate drivers are disabled and the soft-start capacitor is fully discharged. When the fault condition is no longer present a soft-start sequence is initiated. Following a second-level current limit detection (CS2), the soft-start current source is reduced to 1 μ A until the first output pulse is generated by the PWM comparator. The current source returns to the nominal 20- μ A level after the first output pulse (approximately 1 V at the SS pin).

7.3.11 Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event the maximum junction temperature is exceeded. When activated, typically at 165°C, the controller is forced into a low-power standby state with the output drivers and the bias regulator disabled. The device restarts after the thermal hysteresis (typically 25°C). During a restart after thermal shutdown, the soft-start capacitor is fully discharged and then charged in the low-current mode (1 μ A) similar to a second-level current limit event. The thermal protection feature is provided to prevent catastrophic failures from accidental device overheating.

7.4 Device Functional Modes

The LM5025 active clamp voltage mode PWM controller has six functional modes. The modes transition diagram is shown in [Figure 12](#).

- UVLO Mode
- Soft-Start Mode
- Normal Operation Mode
- Cycle-by-Cycle Current Limit Mode
- Hiccup Mode
- Thermal Shut Down Mode

Figure 12. Functional Mode Transition Diagram

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers must validate and test their design implementation to confirm system functionality.

8.1 Application Information

The LM5025 PWM controller contains all of the features necessary to implement power converters using the active clamp and reset technique. This section provides design guidance for a typical active clamp forward converter design. An actual application schematic of a 36-V to 78-V input, 3.3-V, 30-A output active clamp forward converter is also provided in [Figure 21](#).

8.2 Typical Application

[Figure 13](#) shows a simplified schematic of an active clamp forward power converter.

Power converters based on the forward topology offer high-efficiency and good power-handling capability in applications up to several hundred Watts. The operation of the transformer in a forward topology does not inherently self-reset each power switching cycle, a mechanism to reset the transformer is required. The active clamp reset mechanism is presently finding extensive use in medium-level power converters in the 50 W to 200 W range.

The forward converter is derived from the Buck topology family, employing a single modulating power switch. The main difference between the topologies is the forward topology employs a transformer to provide input and output ground isolation and a step down or step up function.

Each cycle, the main primary switch turns on and applies the input voltage across the primary winding. The transformer turns the voltage to a lower-level on the secondary side. The clamp capacitor along with the reset switch reverse biases the transformer primary each cycle when the main switch turns off. This reverse voltage resets the transformer. The clamp capacitor voltage is $V_{IN} / (1-D)$.

The secondary rectification employs self-driven synchronous rectification to maintain high-efficiency and ease of drive.

Feedback from the output is processed by an amplifier and reference, generating an error voltage, which is coupled back to the primary side control through an opto-coupler. The LM5025 voltage mode controller pulse width modulates the error signal with a ramp signal derived from the input voltage. Deriving the ramp signal slope from the input voltage provides line feed-forward, which improves line transient rejection. The LM5025 also provides a controlled delay necessary for the reset switch.

Typical Application (continued)

Figure 13. Simplified Active Clamp Forward Power Converter

8.2.1 Design Requirements

This typical application provides an example of a fully-functional power converter based on the active clamp forward topology in an industry standard half-brick footprint.

The design requirements are:

- Input: 36 V to 78 V (100-V peak)
- Output Voltage: 3.3 V
- Output Current: 0 A to 30 A
- Measured Efficiency: 90.5% at 30 A, 92.5% at 15 A
- Frequency of Operation: 230 kHz
- Board Size: 2.3 × 2.4 × 0.5 inches
- Load Regulation: 1%
- Line Regulation: 0.1%
- Line UVLO, Hiccup Current Limit

8.2.2 Detailed Design Procedure

Before the controller design begins, the power stage design must be completed. This section describes the calculations needed to configure the LM5025 controller to meet the power stage design requirements.

8.2.2.1 Oscillator

The desired switching frequency F is set by a resistor connected between R_T pin and ground. The resistance value R_T is calculated from [Equation 1](#):

$$R_T = (5725/F)^{1.026}$$

where

- F is in kHz and R_T in kΩ.

(1)

Typical Application (continued)

8.2.2.2 Soft-Start Ramp Time and Hiccup Interval

The soft-start ramp time and hiccup interval is programmed by a capacitor (C_{SS}) on the SS pin to ground. The soft-start ramp time is determined by comparing the SS pin voltage with COMP pin voltage. When the SS voltage is less than COMP voltage, the COMP voltage is clamped by SS voltage. The PWM duty is limited by the clamped COMP voltage, so that soft-start can be achieved. The first PWM pulse is generated after COMP voltage reaches 1 V. So the soft-start ramp time of the output voltage can be estimated by [Equation 2](#):

$$T_{SS}(\text{ms}) = C_{SS}(\text{nF}) \times \frac{V_{SS} - 1\text{V}}{20\mu\text{A}}$$

where

- V_{SS} is the steady state COMP pin voltage. This voltage is determined by the output voltage, voltage divider, and the compensation network. (2)

In hiccup mode, the SS current source is reduced to 1 μA . When the first PWM pulse is generated, the current source switches to 20 μA , and the power supply tries to start up again. The hiccup interval can be calculated by [Equation 3](#):

$$T_{\text{hiccup}}(\text{ms}) = C_{SS}(\text{nF}) \times \frac{1\text{V}}{1\mu\text{A}} \quad (3)$$

8.2.2.3 Feed-Forward Ramp and Maximum On Time Clamp

An example illustrates the use of the Volt $\times$ Second Clamp comparator to achieve a 50% duty cycle limit, at 200 KHz, at a 48-V line input: A 50% duty cycle at a 200 KHz requires a 2.5 μs of ON time. At 48-V input the Volt $\times$ Second product is 120 V $\times$ μs (48 V $\times$ 2.5 μs). To achieve this clamp level, see [Equation 4](#) and [Equation 5](#):

$$R_{FF} \times C_{FF} = V_{IN} \times T_{ON} / 2.5\text{V} \quad (4)$$

$$48 \times 2.5\mu\text{F} / 2.5 = 48\mu\text{F} \quad (5)$$

Select $C_{FF} = 470\text{pF}$

$R_{FF} = 102\text{k}\Omega$

The recommended capacitor value range for C_{FF} is 100 pF to 1000 pF.

8.2.2.4 Dead Times

The magnitude of the overlap and dead time can be calculated as follows in [Equation 6](#) and [Equation 7](#):

$$\text{Overlap Time (ns)} = 2.8 \times R_{SET} - 1.2 \quad (6)$$

$$\text{Dead Time (ns)} = 2.9 \times R_{SET} + 20$$

where

- R_{SET} in k Ω , Time in ns (7)

9 Power Supply Recommendations

V_{CC} pin is the power supply for the device. There must be a 0.1- μ F to approximately 100- μ F capacitor directly from V_{CC} to ground. REF pin must be bypassed to ground as close as possible to the device using a 0.1- μ F capacitor.

10 Layout

10.1 Layout Guidelines

- Connect two grounds PGND (power ground) and AGND (analog ground) directly as device ground ICGND. The connection must be as close to the pins as possible.
- If there are multiple PCB layers and there is an inner ground layer, use two vias or one big via on GND and connect them to the inner ground layer (ICGND).
- The power stage ground PSGND should be separated with the ICGND. PSGND and ICGND should be connected at a single point close to the device.
- The bypass capacitors to the V_{CC} pin and REF pin should be as close as possible to the pins and ground (ICGND).
- The filtering capacitors connected to CS1 and CS2 pins should have connections as short as possible to ICGND; if an inner ground layer is available, use vias to connect the capacitors to the ground layer (ICGND).
- The resistors and capacitors connected to the timing configuration pins should be as close as possible to the pins and ground (ICGND).

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
