**WARNING – EXPORT NOTICE:** Recipient agrees to not knowingly export or re-export, directly or indirectly, any product or technical data (as defined by the U.S., EU, and other Export Administration Regulations) including software, or any controlled product restricted by other applicable national regulations, received from Disclosing party under this Agreement, or any direct product of such technology, to any destination to which such export or re-export is restricted or prohibited by U.S. or other applicable laws, without obtaining prior authorization from U.S. Department of Commerce and other competent Government authorities to the extent required by those laws.

According to our best knowledge of the state and end-use of this product or technology, and in compliance with the export control regulations of dual-use goods in force in the origin and exporting countries, this technology is classified as follows:

- US ECCN: EAR99
- EU ECCN: EAR99

And may require export or re-export license for shipping it in compliance with the applicable regulations of certain countries.

| 2.3.6 Data Types .....                                                 | 108       |
| 2.4 Memory Model .....                                                 | 108       |
| 2.4.1 Memory Regions, Types and Attributes .....                       | 111       |
| 2.4.2 Memory System Ordering of Memory Accesses .....                  | 112       |
| 2.4.3 Behavior of Memory Accesses .....                                | 112       |
| 2.4.4 Software Ordering of Memory Accesses .....                       | 113       |

|          |                                                          |            |
|----------|----------------------------------------------------------|------------|
| 2.4.5    | Bit-Banding .....                                        | 114        |
| 2.4.6    | Data Storage .....                                       | 116        |
| 2.4.7    | Synchronization Primitives .....                         | 117        |
| 2.5      | Exception Model .....                                    | 118        |
| 2.5.1    | Exception States .....                                   | 119        |
| 2.5.2    | Exception Types .....                                    | 119        |
| 2.5.3    | Exception Handlers .....                                 | 124        |
| 2.5.4    | Vector Table .....                                       | 124        |
| 2.5.5    | Exception Priorities .....                               | 125        |
| 2.5.6    | Interrupt Priority Grouping .....                        | 126        |
| 2.5.7    | Exception Entry and Return .....                         | 126        |
| 2.6      | Fault Handling .....                                     | 129        |
| 2.6.1    | Fault Types .....                                        | 130        |
| 2.6.2    | Fault Escalation and Hard Faults .....                   | 130        |
| 2.6.3    | Fault Status Registers and Fault Address Registers ..... | 131        |
| 2.6.4    | Lockup .....                                             | 131        |
| 2.7      | Power Management .....                                   | 132        |
| 2.7.1    | Entering Sleep Modes .....                               | 132        |
| 2.7.2    | Wake Up from Sleep Mode .....                            | 132        |
| 2.8      | Instruction Set Summary .....                            | 133        |
| <b>3</b> | <b>Cortex-M4 Peripherals .....</b>                       | <b>140</b> |
| 3.1      | Functional Description .....                             | 140        |
| 3.1.1    | System Timer (SysTick) .....                             | 141        |
| 3.1.2    | Nested Vectored Interrupt Controller (NVIC) .....        | 142        |
| 3.1.3    | System Control Block (SCB) .....                         | 143        |
| 3.1.4    | Memory Protection Unit (MPU) .....                       | 143        |
| 3.1.5    | Floating-Point Unit (FPU) .....                          | 148        |
| 3.2      | Register Map .....                                       | 152        |
| 3.3      | System Timer (SysTick) Register Descriptions .....       | 155        |
| 3.4      | NVIC Register Descriptions .....                         | 159        |
| 3.5      | System Control Block (SCB) Register Descriptions .....   | 169        |
| 3.6      | Memory Protection Unit (MPU) Register Descriptions ..... | 198        |
| 3.7      | Floating-Point Unit (FPU) Register Descriptions .....    | 207        |
| <b>4</b> | <b>JTAG Interface .....</b>                              | <b>213</b> |

## List of Figures

|              |                                                                                     |     |
|--------------|-------------------------------------------------------------------------------------|-----|
| Figure 1-1.  | Tiva™ TM4C129DNCPDT Microcontroller High-Level Block Diagram .....                  | 58  |
| Figure 2-1.  | CPU Block Diagram .....                                                             | 87  |
| Figure 2-2.  | TPIU Block Diagram .....                                                            | 88  |
| Figure 2-3.  | Cortex-M4F Register Set .....                                                       | 91  |
| Figure 2-4.  | Bit-Band Mapping .....                                                              | 116 |
| Figure 2-5.  | Data Storage .....                                                                  | 117 |
| Figure 2-6.  | Vector Table .....                                                                  | 125 |
| Figure 2-7.  | Exception Stack Frame .....                                                         | 128 |
| Figure 3-1.  | SRD Use Example .....                                                               | 146 |
| Figure 3-2.  | FPU Register Bank .....                                                             | 149 |
| Figure 4-1.  | JTAG Module Block Diagram .....                                                     | 214 |
| Figure 4-2.  | Test Access Port State Machine .....                                                | 218 |
| Figure 4-3.  | IDCODE Register Format .....                                                        | 224 |
| Figure 4-4.  | BYPASS Register Format .....                                                        | 224 |
| Figure 4-5.  | Boundary Scan Register Format .....                                                 | 224 |
| Figure 5-1.  | Basic $\overline{\text{RST}}$ Configuration .....                                   | 230 |
| Figure 5-2.  | External Circuitry to Extend Power-On Reset .....                                   | 230 |
| Figure 5-3.  | Reset Circuit Controlled by Switch .....                                            | 230 |
| Figure 5-4.  | Power Architecture .....                                                            | 235 |
| Figure 5-5.  | Main Clock Tree .....                                                               | 239 |
| Figure 5-6.  | Module Clock Selection .....                                                        | 248 |
| Figure 7-1.  | Hibernation Module Block Diagram .....                                              | 533 |
| Figure 7-2.  | Using a Crystal as the Hibernation Clock Source with a Single Battery Source .....  | 537 |
| Figure 7-3.  | Using a Dedicated Oscillator as the Hibernation Clock Source with VDD3ON Mode ..... | 537 |
| Figure 7-4.  | Using a Regulator for Both $V_{\text{DD}}$ and $V_{\text{BAT}}$ .....               | 538 |
| Figure 7-5.  | Counter Behavior with a TRIM Value of 0x8002 .....                                  | 542 |
| Figure 7-6.  | Counter Behavior with a TRIM Value of 0x7FFC .....                                  | 542 |
| Figure 7-7.  | Tamper Block Diagram .....                                                          | 542 |
| Figure 7-8.  | Tamper Pad with Glitch Filtering .....                                              | 543 |
| Figure 8-1.  | Internal Memory Block Diagram .....                                                 | 601 |
| Figure 8-2.  | Flash Memory Configuration .....                                                    | 605 |
| Figure 8-3.  | Single 256-Bit Prefetch Buffer Set .....                                            | 606 |
| Figure 8-4.  | Four 256-Bit Prefetch Buffer Configuration .....                                    | 606 |
| Figure 8-5.  | Single Cycle Access, 0 Wait States .....                                            | 607 |
| Figure 8-6.  | Prefetch Fills from Flash .....                                                     | 608 |
| Figure 8-7.  | Mirror Mode Function .....                                                          | 609 |
| Figure 9-1.  | $\mu$ DMA Block Diagram .....                                                       | 679 |
| Figure 9-2.  | Example of Ping-Pong $\mu$ DMA Transaction .....                                    | 686 |
| Figure 9-3.  | Memory Scatter-Gather, Setup and Configuration .....                                | 688 |
| Figure 9-4.  | Memory Scatter-Gather, $\mu$ DMA Copy Sequence .....                                | 689 |
| Figure 9-5.  | Peripheral Scatter-Gather, Setup and Configuration .....                            | 691 |
| Figure 9-6.  | Peripheral Scatter-Gather, $\mu$ DMA Copy Sequence .....                            | 692 |
| Figure 10-1. | Digital I/O Pads .....                                                              | 748 |
| Figure 10-2. | Analog/Digital I/O Pads .....                                                       | 749 |
| Figure 10-3. | GPIO DATA Write Example .....                                                       | 750 |

|               |                                                                                                  |      |
|---------------|--------------------------------------------------------------------------------------------------|------|
| Figure 10-4.  | GPIODATA Read Example .....                                                                      | 750  |
| Figure 11-1.  | EPI Block Diagram .....                                                                          | 818  |
| Figure 11-2.  | SDRAM Non-Blocking Read Cycle .....                                                              | 825  |
| Figure 11-3.  | SDRAM Normal Read Cycle .....                                                                    | 826  |
| Figure 11-4.  | SDRAM Write Cycle .....                                                                          | 827  |
| Figure 11-5.  | iRDY Access Stalls, IRDYDLY==01, 10, 11 .....                                                    | 837  |
| Figure 11-6.  | iRDY Signal Connection .....                                                                     | 837  |
| Figure 11-7.  | PSRAM Burst Read .....                                                                           | 840  |
| Figure 11-8.  | PSRAM Burst Write .....                                                                          | 840  |
| Figure 11-9.  | Read Delay During Refresh Event .....                                                            | 841  |
| Figure 11-10. | Write Delay During Refresh Event .....                                                           | 842  |
| Figure 11-11. | Example Schematic for Muxed Host-Bus 16 Mode .....                                               | 843  |
| Figure 11-12. | Host-Bus Read Cycle, MODE = 0x1, WRHIGH = 0, RDHIGH = 0 .....                                    | 846  |
| Figure 11-13. | Host-Bus Write Cycle, MODE = 0x1, WRHIGH = 0, RDHIGH = 0 .....                                   | 846  |
| Figure 11-14. | Host-Bus Write Cycle with Multiplexed Address and Data, MODE = 0x0, WRHIGH = 0, RDHIGH = 0 ..... | 847  |
| Figure 11-15. | Host-Bus Write Cycle with Multiplexed Address and Data and ALE with Dual or Quad CSn .....       | 847  |
| Figure 11-16. | Continuous Read Mode Accesses .....                                                              | 847  |
| Figure 11-17. | Write Followed by Read to External FIFO .....                                                    | 848  |
| Figure 11-18. | Two-Entry FIFO .....                                                                             | 848  |
| Figure 11-19. | Single-Cycle Single Write Access, FRM50=0, FRMCNT=0, WR2CYC=0 .....                              | 851  |
| Figure 11-20. | Two-Cycle Read, Write Accesses, FRM50=0, FRMCNT=0, WR2CYC=1 .....                                | 852  |
| Figure 11-21. | Read Accesses, FRM50=0, FRMCNT=0 .....                                                           | 852  |
| Figure 11-22. | FRAME Signal Operation, FRM50=0 and FRMCNT=0 .....                                               | 853  |
| Figure 11-23. | FRAME Signal Operation, FRM50=0 and FRMCNT=1 .....                                               | 853  |
| Figure 11-24. | FRAME Signal Operation, FRM50=0 and FRMCNT=2 .....                                               | 853  |
| Figure 11-25. | FRAME Signal Operation, FRM50=1 and FRMCNT=0 .....                                               | 853  |
| Figure 11-26. | FRAME Signal Operation, FRM50=1 and FRMCNT=1 .....                                               | 854  |
| Figure 11-27. | FRAME Signal Operation, FRM50=1 and FRMCNT=2 .....                                               | 854  |
| Figure 11-28. | EPI Clock Operation, CLKGATE=1, WR2CYC=0 .....                                                   | 854  |
| Figure 11-29. | EPI Clock Operation, CLKGATE=1, WR2CYC=1 .....                                                   | 855  |
| Figure 13-1.  | AES Block Diagram .....                                                                          | 957  |
| Figure 13-2.  | AES - ECB Feedback Mode .....                                                                    | 961  |
| Figure 13-3.  | AES - CBC Feedback Mode .....                                                                    | 962  |
| Figure 13-4.  | AES Encryption With CTR/ICM Mode .....                                                           | 962  |
| Figure 13-5.  | AES - CFB Feedback Mode .....                                                                    | 963  |
| Figure 13-6.  | AES - F8 Mode .....                                                                              | 964  |
| Figure 13-7.  | AES - XTS Operation .....                                                                        | 964  |
| Figure 13-8.  | AES - F9 Operation .....                                                                         | 965  |
| Figure 13-9.  | AES - CBC-MAC Authentication Mode .....                                                          | 966  |
| Figure 13-10. | AES - GCM Operation .....                                                                        | 967  |

| Register 29:                | Sleep / Deep-Sleep Power Mode Status (SDPMST), offset 0x1CC .....                          | 312        |
| Register 30:                | Reset Behavior Control Register (RESBEHAVCTL), offset 0x1D8 .....                          | 315        |
| Register 31:                | Hardware System Service Request (HSSR), offset 0x1F4 .....                                 | 317        |
| Register 32:                | USB Power Domain Status (USBPDS), offset 0x280 .....                                       | 318        |

|              |                                                                                                |     |
|--------------|------------------------------------------------------------------------------------------------|-----|
| Register 33: | USB Memory Power Control (USBMPC), offset 0x284 .....                                          | 319 |
| Register 34: | Ethernet MAC Power Domain Status (EMACPDS), offset 0x288 .....                                 | 320 |
| Register 35: | Ethernet MAC Memory Power Control (EMACMPC), offset 0x28C .....                                | 321 |
| Register 36: | CAN 0 Power Domain Status (CAN0PDS), offset 0x298 .....                                        | 322 |
| Register 37: | CAN 0 Memory Power Control (CAN0MPC), offset 0x29C .....                                       | 323 |
| Register 38: | CAN 1 Power Domain Status (CAN1PDS), offset 0x2A0 .....                                        | 324 |
| Register 39: | CAN 1 Memory Power Control (CAN1MPC), offset 0x2A4 .....                                       | 325 |
| Register 40: | Watchdog Timer Peripheral Present (PPWD), offset 0x300 .....                                   | 326 |
| Register 41: | 16/32-Bit General-Purpose Timer Peripheral Present (PPTIMER), offset 0x304 .....               | 327 |
| Register 42: | General-Purpose Input/Output Peripheral Present (PPGPIO), offset 0x308 .....                   | 329 |
| Register 43: | Micro Direct Memory Access Peripheral Present (PPDMA), offset 0x30C .....                      | 332 |
| Register 44: | EPI Peripheral Present (PPEPI), offset 0x310 .....                                             | 333 |
| Register 45: | Hibernation Peripheral Present (PPHIB), offset 0x314 .....                                     | 334 |
| Register 46: | Universal Asynchronous Receiver/Transmitter Peripheral Present (PPUART), offset<br>0x318 ..... | 335 |
| Register 47: | Synchronous Serial Interface Peripheral Present (PPSSI), offset 0x31C .....                    | 337 |
| Register 48: | Inter-Integrated Circuit Peripheral Present (PPI2C), offset 0x320 .....                        | 339 |
| Register 49: | Universal Serial Bus Peripheral Present (PPUSB), offset 0x328 .....                            | 341 |
| Register 50: | Ethernet PHY Peripheral Present (PPEPHY), offset 0x330 .....                                   | 342 |
| Register 51: | Controller Area Network Peripheral Present (PPCAN), offset 0x334 .....                         | 343 |
| Register 52: | Analog-to-Digital Converter Peripheral Present (PPADC), offset 0x338 .....                     | 344 |
| Register 53: | Analog Comparator Peripheral Present (PPACMP), offset 0x33C .....                              | 345 |
| Register 54: | Pulse Width Modulator Peripheral Present (PPPWM), offset 0x340 .....                           | 346 |
| Register 55: | Quadrature Encoder Interface Peripheral Present (PPQEI), offset 0x344 .....                    | 347 |
| Register 56: | Low Pin Count Interface Peripheral Present (PPLPC), offset 0x348 .....                         | 348 |
| Register 57: | Platform Environment Control Interface Peripheral Present (PPPECI), offset 0x350 .....         | 349 |
| Register 58: | Fan Control Peripheral Present (PPFAN), offset 0x354 .....                                     | 350 |
| Register 59: | EEPROM Peripheral Present (PPEEPROM), offset 0x358 .....                                       | 351 |
| Register 60: | 32/64-Bit Wide General-Purpose Timer Peripheral Present (PPWTIMER), offset 0x35C .....         | 352 |
| Register 61: | Remote Temperature Sensor Peripheral Present (PPRTS), offset 0x370 .....                       | 353 |
| Register 62: | CRC and Cryptographic Modules Peripheral Present (PPCCM), offset 0x374 .....                   | 354 |
| Register 63: | LCD Peripheral Present (PPLCD), offset 0x390 .....                                             | 355 |
| Register 64: | 1-Wire Peripheral Present (PPOWIRE), offset 0x398 .....                                        | 356 |
| Register 65: | Ethernet MAC Peripheral Present (PPEMAC), offset 0x39C .....                                   | 357 |
| Register 66: | Power Regulator Bus Peripheral Present (PPPRB), offset 0x3A0 .....                             | 358 |
| Register 67: | Human Interface Master Peripheral Present (PPHIM), offset 0x3A4 .....                          | 359 |
| Register 68: | Watchdog Timer Software Reset (SRWD), offset 0x500 .....                                       | 360 |
| Register 69: | 16/32-Bit General-Purpose Timer Software Reset (SRTIMER), offset 0x504 .....                   | 361 |
| Register 70: | General-Purpose Input/Output Software Reset (SRGPIO), offset 0x508 .....                       | 363 |
| Register 71: | Micro Direct Memory Access Software Reset (SRDMA), offset 0x50C .....                          | 366 |
| Register 72: | EPI Software Reset (SREPI), offset 0x510 .....                                                 | 367 |
| Register 73: | Hibernation Software Reset (SRHIB), offset 0x514 .....                                         | 368 |
| Register 74: | Universal Asynchronous Receiver/Transmitter Software Reset (SRUART), offset 0x518 .....        | 369 |
| Register 75: | Synchronous Serial Interface Software Reset (SRSSI), offset 0x51C .....                        | 371 |
| Register 76: | Inter-Integrated Circuit Software Reset (SRI2C), offset 0x520 .....                            | 373 |
| Register 77: | Universal Serial Bus Software Reset (SRUSB), offset 0x528 .....                                | 375 |
| Register 78: | Controller Area Network Software Reset (SRCAN), offset 0x534 .....                             | 376 |
| Register 79: | Analog-to-Digital Converter Software Reset (SRADC), offset 0x538 .....                         | 377 |

|               |                                                                                                               |     |
|---------------|---------------------------------------------------------------------------------------------------------------|-----|
| Register 80:  | Analog Comparator Software Reset (SRACMP), offset 0x53C .....                                                 | 378 |
| Register 81:  | Pulse Width Modulator Software Reset (SRPWM), offset 0x540 .....                                              | 379 |
| Register 82:  | Quadrature Encoder Interface Software Reset (SRQEI), offset 0x544 .....                                       | 380 |
| Register 83:  | EEPROM Software Reset (SREEPROM), offset 0x558 .....                                                          | 381 |
| Register 84:  | CRC and Cryptographic Modules Software Reset (SRCCM), offset 0x574 .....                                      | 382 |
| Register 85:  | Ethernet MAC Software Reset (SREMAC), offset 0x59C .....                                                      | 383 |
| Register 86:  | Watchdog Timer Run Mode Clock Gating Control (RCGCWD), offset 0x600 .....                                     | 384 |
| Register 87:  | 16/32-Bit General-Purpose Timer Run Mode Clock Gating Control (RCGCTIMER), offset<br>0x604 .....              | 385 |

|              |            | <ul style="list-style-type: none"> <li>– Added subsections to "Flash Memory" section about Execute-Only Protection, Read-Only Protection and Permanently Disabling Debug.</li> <li>– Removed INVPL bit from <b>EEPROM Done Status (EEDONE)</b> register.</li> <li>– Updated table "MEMTIM0 Register Configuration vs. Frequency" with lower wait states, and improved performance values.</li> <li>– Added EEPROM initialization code to "EEPROM Initialization and Configuration" section.</li> <li>■ In the ADC chapter: <ul style="list-style-type: none"> <li>– Added section "Sample and Hold Window Control" and clarified section "Sample Phase Control".</li> <li>– Clarified description of <b>ADC Sample Phase Control (ADCSPC)</b> register.</li> </ul> </li> <li>■ Updated Electrical Characteristics chapter based on characterization information received.</li> <li>■ Additional minor data sheet clarifications and corrections.</li> </ul> |
| October 2013 | 15440.2698 | Initial release of NDA data sheet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## About This Document

This data sheet provides reference information for the TM4C129DNCPDT microcontroller, describing the functional blocks of the system-on-chip (SoC) device designed around the ARM® Cortex™-M4F core.

## Audience

This manual is intended for system software developers, hardware designers, and application developers.

## About This Manual

This document is organized into sections that correspond to each major feature.

**Table 2. Documentation Conventions**

| Notation                              | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>General Register Notation</b>      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>REGISTER</b>                       | APB registers are indicated in uppercase bold. For example, <b>PBORCTL</b> is the Power-On and Brown-Out Reset Control register. If a register name contains a lowercase n, it represents more than one register. For example, <b>SRCRn</b> represents any (or all) of the three Software Reset Control registers: <b>SRCR0</b> , <b>SRCR1</b> , and <b>SRCR2</b> .                                                                                            |
| bit                                   | A single bit in a register.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| bit field                             | Two or more consecutive and related bits.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| offset 0xnnn                          | A hexadecimal increment to a register's address, relative to that module's base address as specified in Table 2-4 on page 108.                                                                                                                                                                                                                                                                                                                                 |
| Register N                            | Registers are numbered consecutively throughout the document to aid in referencing them. The register number has no meaning to software.                                                                                                                                                                                                                                                                                                                       |
| reserved                              | Register bits marked <i>reserved</i> are reserved for future use. In most cases, reserved bits are set to 0; however, user software should not rely on the value of a reserved bit. To provide software compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                              |
| yy:xx                                 | The range of register bits inclusive from xx to yy. For example, 31:15 means bits 15 through 31 in that register.                                                                                                                                                                                                                                                                                                                                              |
| <b>Register Bit/Field Types</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RC                                    | Software can read this field. The bit or field is cleared by hardware after reading the bit/field.                                                                                                                                                                                                                                                                                                                                                             |
| RO                                    | Software can read this field. Always write the chip reset value.                                                                                                                                                                                                                                                                                                                                                                                               |
| RW                                    | Software can read or write this field.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| RWC                                   | Software can read or write this field. Writing to it with any value clears the register.                                                                                                                                                                                                                                                                                                                                                                       |
| RW1C                                  | Software can read or write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. This register type is primarily used for clearing interrupt status bits where the read operation provides the interrupt status and the write of the read value clears only the interrupts being reported at the time the register was read. |
| RW1S                                  | Software can read or write a 1 to this field. A write of a 0 to a RW1S bit does not affect the bit value in the register.                                                                                                                                                                                                                                                                                                                                      |
| W1C                                   | Software can write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. A read of the register returns no meaningful data. This register is typically used to clear the corresponding bit in an interrupt register.                                                                                                         |
| WO                                    | Only a write by software is valid; a read of the register returns no meaningful data.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Register Bit/Field Reset Value</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 0                                     | Bit cleared to 0 on chip reset.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 1                                     | Bit set to 1 on chip reset.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -                                     | Nondeterministic.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Pin/Signal Notation</b>            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| [ ]                                   | Pin alternate function; a pin defaults to the signal without the brackets.                                                                                                                                                                                                                                                                                                                                                                                     |
| pin                                   | Refers to the physical connection on the package.                                                                                                                                                                                                                                                                                                                                                                                                              |
| signal                                | Refers to the electrical signal encoding of a pin.                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 2. Documentation Conventions (*continued*)**

| Notation                   | Meaning                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| assert a signal            | Change the value of the signal from the logically False state to the logically True state. For active High signals, the asserted signal value is 1 (High); for active Low signals, the asserted signal value is 0 (Low). The active polarity (High or Low) is defined by the signal name (see SIGNAL and $\overline{\text{SIGNAL}}$ below). |
| deassert a signal          | Change the value of the signal from the logically True state to the logically False state.                                                                                                                                                                                                                                                  |
| $\overline{\text{SIGNAL}}$ | Signal names are in uppercase and in the Courier font. An overbar on a signal name indicates that it is active Low. To assert $\overline{\text{SIGNAL}}$ is to drive it Low; to deassert $\overline{\text{SIGNAL}}$ is to drive it High.                                                                                                    |
| SIGNAL                     | Signal names are in uppercase and in the Courier font. An active High signal has no overbar. To assert SIGNAL is to drive it High; to deassert SIGNAL is to drive it Low.                                                                                                                                                                   |
| <b>Numbers</b>             |                                                                                                                                                                                                                                                                                                                                             |
| X                          | An uppercase X indicates any of several values is allowed, where X can be any legal pattern. For example, a binary value of 0X00 can be either 0100 or 0000, a hex value of 0xX is 0x0 or 0x1, and so on.                                                                                                                                   |
| 0x                         | Hexadecimal numbers have a prefix of 0x. For example, 0x00FF is the hexadecimal number FF. All other numbers within register tables are assumed to be binary. Within conceptual information, binary numbers are indicated with a b suffix, for example, 1011b, and decimal numbers are written without a prefix or suffix.                  |

# 1 Architectural Overview

Texas Instrument's Tiva™ C Series microcontrollers provide designers a high-performance ARM® Cortex™-M-based architecture with a broad set of integration capabilities and a strong ecosystem of software and development tools. Targeting performance and flexibility, the Tiva™ C Series architecture offers a 120 MHz Cortex-M with FPU, a variety of integrated memories and multiple programmable GPIO. Tiva™ C Series devices offer consumers compelling cost-effective solutions by integrating application-specific peripherals and providing a comprehensive library of software tools which minimize board costs and design-cycle time. Offering quicker time-to-market and cost savings, the Tiva™ C Series microcontrollers are the leading choice in high-performance 32-bit applications.

This chapter contains an overview of the Tiva™ C Series microcontrollers as well as details on the TM4C129DNCPDT microcontroller:

- “Tiva™ C Series Overview” on page 55
- “TM4C129DNCPDT Microcontroller Overview” on page 56
- “TM4C129DNCPDT Microcontroller Features” on page 59
- “TM4C129DNCPDT Microcontroller Hardware Details” on page 84

- “Support Information” on page 84

## 1.1 Tiva™ C Series Overview

The Tiva™ C Series ARM Cortex-M4 microcontrollers provide top performance and advanced integration. The product family is positioned for cost-effective applications requiring significant control processing and connectivity capabilities such as:

- Industrial communication equipment
- Network appliances, gateways & adapters
- Residential & commercial site monitoring & control
- Remote connectivity & monitoring
- Security/access systems
- HMI control panels
- Factory automation control
- Test and measurement equipment
- Fire & security systems
- Motion control & power inversion
- Medical instrumentation
- Gaming equipment
- Electronic point-of-sale (POS) displays
- Smart Energy/Smart Grid solutions
- Intelligent lighting control
- Vehicle tracking

Tiva™ C Series microcontrollers integrate a large variety of rich communication features to enable a new class of highly connected designs with the ability to allow critical, real-time control between performance and power. The microcontrollers feature integrated communication peripherals along with other high-performance analog and digital functions to offer a strong foundation for many different target uses, spanning from human machine interface to networked system management controllers.

In addition, Tiva™ C Series microcontrollers offer the advantages of ARM's widely available development tools, System-on-Chip (SoC) infrastructure, and a large user community. Additionally, these microcontrollers use ARM's Thumb®-compatible Thumb-2 instruction set to reduce memory requirements and, thereby, cost. Finally, the TM4C129DNCPDT microcontroller is code-compatible to all members of the extensive Tiva™ C Series, providing flexibility to fit precise needs.

Texas Instruments offers a complete solution to get to market quickly, with evaluation and development boards, white papers and application notes, an easy-to-use peripheral driver library, and a strong support, sales, and distributor network.

## 1.2 TM4C129DNCPDT Microcontroller Overview

The TM4C129DNCPDT microcontroller combines complex integration and high performance with the features shown in Table 1-1.

**Table 1-1. TM4C129DNCPDT Microcontroller Features**

| Feature                                             | Description                                                                                |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------|
| <b>Performance</b>                                  |                                                                                            |
| Core                                                | ARM Cortex-M4F processor core                                                              |
| Performance                                         | 120-MHz operation; 150 DMIPS performance                                                   |
| Flash                                               | 1024 KB Flash memory                                                                       |
| System SRAM                                         | 256 KB single-cycle System SRAM                                                            |
| EEPROM                                              | 6KB of EEPROM                                                                              |
| Internal ROM                                        | Internal ROM loaded with TivaWare™ for C Series software                                   |
| External Peripheral Interface (EPI)                 | 8-/16-/32-bit dedicated interface for peripherals and memory                               |
| <b>Security</b>                                     |                                                                                            |
| Cyclical Redundancy Check (CRC) Hardware            | 16-/32-bit Hash function that supports four CRC forms                                      |
| Advanced Encryption Standard (AES)                  | Hardware accelerated data encryption and decryption based on 128-, 192-, and 256-bit keys  |
| Data Encryption Standard (DES)                      | Block cipher implementation with 168-bit effective key length                              |
| Hardware Accelerated Hash (SHA/MD5)                 | Advanced hash engine that supports SHA-1, SHA-2 or MD5 Hash computation                    |
| Tamper                                              | Support for four tamper inputs and configurable tamper event response                      |
| <b>Communication Interfaces</b>                     |                                                                                            |
| Universal Asynchronous Receivers/Transmitter (UART) | Eight UARTs                                                                                |
| Quad Synchronous Serial Interface (QSSI)            | Four SSI modules with Bi-, Quad- and advanced SSI support                                  |
| Inter-Integrated Circuit (I <sup>2</sup> C)         | Ten I <sup>2</sup> C modules with four transmission speeds including high-speed mode       |
| Controller Area Network (CAN)                       | Two CAN 2.0 A/B controllers                                                                |
| Ethernet MAC                                        | 10/100 Ethernet MAC with Media Independent Interface (MII) and Reduced MII (RMII)          |
| Universal Serial Bus (USB)                          | USB 2.0 OTG/Host/Device with ULPI interface option and Link Power Management (LPM) support |
| <b>System Integration</b>                           |                                                                                            |
| Micro Direct Memory Access (μDMA)                   | ARM® PrimeCell® 32-channel configurable μDMA controller                                    |
| General-Purpose Timer (GPTM)                        | Eight 16/32-bit GPTM blocks                                                                |
| Watchdog Timer (WDT)                                | Two watchdog timers                                                                        |

**Table 1-1. TM4C129DNCPDT Microcontroller Features (continued)**

| Feature                             | Description                                                                                       |
|-------------------------------------|---------------------------------------------------------------------------------------------------|
| Hibernation Module (HIB)            | Low-power battery-backed Hibernation module                                                       |
| General-Purpose Input/Output (GPIO) | 15 physical GPIO blocks                                                                           |
| <b>Advanced Motion Control</b>      |                                                                                                   |
| Pulse Width Modulator (PWM)         | One PWM module, with four PWM generator blocks and a control block, for a total of 8 PWM outputs. |
| Quadrature Encoder Interface (QEI)  | One QEI module                                                                                    |
| <b>Analog Support</b>               |                                                                                                   |
| Analog-to-Digital Converter (ADC)   | Two 12-bit ADC modules, each with a maximum sample rate of two million samples/second             |
| Analog Comparator Controller        | Three independent integrated analog comparators                                                   |
| Digital Comparator                  | 16 digital comparators                                                                            |
| JTAG and Serial Wire Debug (SWD)    | One JTAG module with integrated ARM SWD                                                           |
| <b>Package Information</b>          |                                                                                                   |
| Package                             | 128-pin TQFP                                                                                      |
| Operating Range (Ambient)           | Industrial (-40°C to 85°C) temperature range<br>Extended (-40°C to 105°C) temperature range       |

Figure 1-1 on page 58 shows the features on the TM4C129DNCPDT microcontroller. Note that there are two on-chip buses that connect the core to the peripherals. The Advanced Peripheral Bus (APB) bus is the legacy bus. The Advanced High-Performance Bus (AHB) bus provides better back-to-back access performance than the APB bus.

### ***Texas Instruments-Production Data***

## 1.3 TM4C129DNCPDT Microcontroller Features

The TM4C129DNCPDT microcontroller component features and general function are discussed in more detail in the following section.

### 1.3.1 ARM Cortex-M4F Processor Core

All members of the Tiva™ C Series, including the TM4C129DNCPDT microcontroller, are designed around an ARM Cortex-M processor core. The ARM Cortex-M processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

#### 1.3.1.1 Processor Core (see page 85)

- 32-bit ARM Cortex-M4F architecture optimized for small-footprint embedded applications
- 120-MHz operation; 150 DMIPS performance
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- 16-bit SIMD vector processing unit
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast digital-signal-processing orientated multiply accumulate
- Saturating arithmetic for signal processing
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing

- Migration from the ARM7™ processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage up to specific frequencies; see “Internal Memory” on page 600 for more information.
- Ultra-low power consumption with integrated sleep modes

#### **1.3.1.2 System Timer (SysTick) (see page 141)**

ARM Cortex-M4F includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit, clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine
- A high-speed alarm timer using the system clock
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter
- A simple counter used to measure time to completion and time used
- An internal clock-source control based on missing/meeting durations

#### **1.3.1.3 Nested Vectored Interrupt Controller (NVIC) (see page 142)**

The TM4C129DNCPDT controller includes the ARM Nested Vectored Interrupt Controller (NVIC). The NVIC and Cortex-M4F prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The interrupt vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, meaning that back-to-back interrupts can be performed without the overhead of state saving and restoration. Software can set eight priority levels on 7 exceptions (system handlers) and 106 interrupts.

- Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining (these values reflect no FPU stacking)
- External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications
- Dynamically reprioritizable interrupts
- Exceptional interrupt handling via hardware implementation of required register manipulations

#### **1.3.1.4 System Control Block (SCB) (see page 143)**

The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions.

#### **1.3.1.5 Memory Protection Unit (MPU) (see page 143)**

The MPU supports the standard ARM7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

### 1.3.1.6 Floating-Point Unit (FPU) (see page 148)

The FPU fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

- 32-bit instructions for single-precision (C float) data-processing operations
- Combined multiply and accumulate instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication with optional accumulate, division, and square-root
- Hardware support for denormals and all IEEE rounding modes
- 32 dedicated 32-bit single-precision registers, also addressable as 16 double-word registers
- Decoupled three stage pipeline

### 1.3.2 On-Chip Memory

The TM4C129DNCPDT microcontroller is integrated with the following set of on-chip memory and features:

- 256 KB single-cycle SRAM
- 1024 KB Flash memory
- 6KB EEPROM
- Internal ROM loaded with TivaWare™ for C Series software:
  - TivaWare™ Peripheral Driver Library
  - TivaWare Boot Loader
  - Advanced Encryption Standard (AES) cryptography tables
  - Cyclic Redundancy Check (CRC) error detection functionality

#### 1.3.2.1 SRAM (see page 602)

The TM4C129DNCPDT microcontroller provides 256 KB of single-cycle on-chip SRAM. The internal SRAM of the device is located at offset 0x2000.0000 of the device memory map.

The SRAM is implemented using four 32-bit wide interleaving SRAM banks (separate SRAM arrays) which allow for increased speed between memory accesses. The SRAM memory provides nearly 2 GB/s memory bandwidth at a 120 MHz clock frequency.

Because read-modify-write (RMW) operations are very time consuming, ARM has introduced *bit-banding* technology in the Cortex-M4F processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

Data can be transferred to and from SRAM by the following masters:

- $\mu$ DMA
- USB
- Ethernet Controller

### 1.3.2.2 Flash Memory (see page 604)

The TM4C129DNCPDT microcontroller provides 1024 KB of on-chip Flash memory. The Flash memory is configured as four banks of 16K x 128 bits (4 \* 256 KB total) which are two-way interleaved. Memory blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

The TM4C129DNCPDT microcontroller provides enhanced performance and power savings by implementation of two sets of instruction prefetch buffers. Each prefetch buffer is 2 x 256 bits and can be combined as a 4 x 256-bit prefetch buffer.

The Flash can also be accessed by the  $\mu$ DMA in Run Mode.

### 1.3.2.3 ROM (see page 602)

The TM4C129DNCPDT ROM is preprogrammed with the following software and programs:

- TivaWare Peripheral Driver Library
- TivaWare Boot Loader
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error-detection functionality

The TivaWare Peripheral Driver Library is a royalty-free software library for controlling on-chip peripherals with a boot-loader capability. The library performs both peripheral initialization and control functions, with a choice of polled or interrupt-driven peripheral support. In addition, the library is designed to take full advantage of the stellar interrupt performance of the ARM Cortex-M4F core. No special pragmas or custom assembly code prologue/epilogue functions are required. For applications that require in-field programmability, the royalty-free TivaWare Boot Loader can act as an application loader and support in-field firmware updates.

The Advanced Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government. AES is a strong encryption method with reasonable performance and size. In addition, it is fast in both hardware and software, is fairly easy to implement, and requires little memory. The Texas Instruments encryption package is available with full source code, and is based on Lesser General Public License (LGPL) source. An LGPL means that the code can be used within an application without any copyleft implications for the application (the code does not automatically become open source). Modifications to the package source, however, must be open source.

CRC (Cyclic Redundancy Check) is a technique to validate a span of data has the same contents as when previously checked. This technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (for example, XOR all bits) because it catches changes more readily.

**Note:** CRC and AES software programs are available in the TivaWare™ for C Series software for backward-compatibility. A device that has enhanced CRC and AES integrated modules should utilize this hardware for best performance. Please refer to “Cyclical Redundancy Check (CRC)” on page 947 and “Advance Encryption Standard Accelerator (AES)” on page 956 for more information.

#### 1.3.2.4 EEPROM (see page 615)

The TM4C129DNCPDT microcontroller includes an EEPROM with the following features:

- 6Kbytes of memory accessible as 1536 32-bit words
- 96 blocks of 16 words (64 bytes) each
- Built-in wear leveling
- Access protection per block
- Lock protection option for the whole peripheral as well as per block using 32-bit to 96-bit unlock codes (application selectable)
- Interrupt support for write completion to avoid polling
- Endurance of 500K writes (when writing at fixed offset in every alternate page in circular fashion) to 15M operations (when cycling through two pages ) per each 2-page block.

#### 1.3.3 External Peripheral Interface (see page 816)

The External Peripheral Interface (EPI) provides access to external devices using a parallel path. Unlike communications peripherals such as SSI, UART, and I<sup>2</sup>C, the EPI is designed to act like a bus to external peripherals and memory.

The EPI has the following features:

- 8/16/32-bit dedicated parallel bus for external peripherals and memory
- Memory interface supports contiguous memory access independent of data bus width, thus enabling code execution directly from SDRAM, SRAM and Flash memory
- Blocking and non-blocking reads
- Separates processor from timing details through use of an internal write FIFO
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for read and write
  - Read channel request asserted by programmable levels on the internal Non-Blocking Read FIFO (NBRFIFO)
  - Write channel request asserted by empty on the internal Write FIFO (WFIFO)

The EPI supports three primary functional modes: Synchronous Dynamic Random Access Memory (SDRAM) mode, Traditional Host-Bus mode, and General-Purpose mode. The EPI module also provides custom GPIOs; however, unlike regular GPIOs, the EPI module uses a FIFO in the same way as a communication mechanism and is speed-controlled using clocking.

- Synchronous Dynamic Random Access Memory (SDRAM) mode
  - Supports x16 (single data rate) SDRAM at up to 60 MHz
  - Supports low-cost SDRAMs up to 64 MB (512 megabits)

- Includes automatic refresh and access to all banks/rows
- Includes a Sleep/Standby mode to keep contents active with minimal power draw
- Multiplexed address/data interface for reduced pin count
- Host-Bus mode
  - Traditional x8 and x16 MCU bus interface capabilities
  - Similar device compatibility options as PIC, ATmega, 8051, and others
  - Access to SRAM, NOR Flash memory, and other devices, with up to 1 MB of addressing in non-multiplexed mode and 256 MB in multiplexed mode (512 MB in Host-Bus 16 mode with no byte selects)
  - Support for up to 512 Mb PSRAM in quad chip select mode, with dedicated configuration register read and write enable.
  - Support of both muxed and de-muxed address and data
  - Access to a range of devices supporting the non-address FIFO x8 and x16 interface variant, with support for external FIFO (XFIFO) EMPTY and FULL signals
  - Speed controlled, with read and write data wait-state counters
  - Support for read/write burst mode to Host Bus
  - Multiple chip select modes including single, dual, and quad chip selects, with and without ALE
  - External IRDY signal provided for stall capability of reads and writes
  - Manual chip-enable (or use extra address pins)
- General-Purpose mode
  - Wide parallel interfaces for fast communications with CPLDs and FPGAs
  - Data widths up to 32 bits
  - Data rates up to 150 MB/second
  - Optional "address" sizes from 4 bits to 20 bits
  - Optional clock output, read/write strobes, framing (with counter-based size), and clock-enable input
- General parallel GPIO
  - 1 to 32 bits, FIFOed with speed control
  - Useful for custom peripherals or for digital data acquisition and actuator controls

### 1.3.4 Cyclical Redundancy Check (CRC) (see page 947)

The TM4C129DNCPDT microcontroller includes a CRC computation module for uses such as message transfer and safety system checks. This module can be used in conjunction with the AES and DES modules. The CRC has the following features:

- Support four major CRC forms:
  - CRC16-CCITT as used by CCITT/ITU X.25
  - CRC16-IBM as used by USB and ANSI
  - CRC32-IEEE as used by IEEE802.3 and MPEG2
  - CRC32C as used by G.Hn
- Allows word and byte feed
- Supports auto-initialization and manual initialization
- Supports MSb and LSb
- Supports CCITT post-processing
- Can be fed by  $\mu$ DMA, Flash memory and code

### 1.3.5 Advanced Encryption Standard (AES) Accelerator (see page 956)

The advanced encryption standard (AES) accelerator module provides hardware-accelerated data encryption and decryption operations based on a binary key. The AES module is a symmetrical cipher modules that supports a 128-bit, 192-bit, or 256-bit key in hardware for both encryption and decryption.

The AES has following features:

- Support for basic AES encrypt and decrypt operations:
  - Galois/Counter Mode (GCM), with basic GHASH operation
  - Counter Mode with CBC-MAC (CCM)
  - XTS Mode
- Availability of the following feedback operating modes:
  - Electronic Code Book Mode (ECB)
  - Cipher Block Chaining Mode (CBC)
  - Counter Mode (CTR)
  - Cipher Feedback Mode (CFB), 128-bit
  - F8 Mode
- Key sizes 128-, 192- and 256-bits

- Support for CBC\_MAC and Fedora 9 (F9) authentication modes
- Basic GHASH operation (when selecting no encryption)
- Key scheduling in hardware
- Support for  $\mu$ DMA transfers
- Fully synchronous design

### 1.3.6 Data Encryption Standard (DES) Accelerator (see page 1008)

The DES module provides hardware accelerated data encryption and decryption functions. The module runs either the single DES or the triple DES (3DES) algorithm and supports electronic codebook (ECB), cipher block chaining (CBC), and cipher feedback (CFB) modes of operation.

The DES accelerator includes the following main features:

- DES/3DES encryption and decryption.
- Feedback modes: ECB, CBC, CFB
- Host interrupt or  $\mu$ DMA driven modes of operation.  $\mu$ DMA support for data and context in/result out
- Fully synchronous design
- Internal wide-bus interface

### 1.3.7 Secure Hash Algorithm / Message Digest Algorithm (SHA/MD5) (see page 1037)

The SHA/MD5 module provides hardware-accelerated hash functions and can run:

- MD5 message digest algorithm developed by Ron Rivest in 1991
- SHA-1 algorithm compliant with the [FIPS 180-3 standard](#)
- SHA-2 (SHA-224 and SHA-256) algorithm compliant with the FIPS 180-3 standard
- Hash message authentication code (HMAC) operation

The algorithms produce a condensed representation of a message or a data file which can then be used to verify the message integrity.

The SHA/MD5 accelerator module includes the following main features:

- Hashing of 0 to  $2^{33} - 2$  bytes of data (of which  $2^{32} - 1$  bytes are in one pass) using the MD5, SHA-1, SHA-224, or SHA-256 hash algorithm (byte granularity only, no support for bit granularity)
- Automatic HMAC key preprocessing for HMAC keys up to 64 bytes
- Host-assisted HMAC key preprocessing for HMAC keys larger than 64 bytes
- HMAC from precomputes (inner/outer digest) for improved performance on small blocks
- Supports  $\mu$ DMA operation for data and context in/result out transfers
- Supports interrupt to read the digest (signature)

### 1.3.8 Serial Communications Peripherals

The TM4C129DNCPDT controller supports both asynchronous and synchronous serial communications with:

- 10/100 Ethernet MAC with Advanced IEEE 1588 PTP hardware and both Media Independent Interface (MII) and Reduced MII (RMII) support
- Two CAN 2.0 A/B controllers
- USB 2.0 Controller OTG/Host/Device with optional high speed using external PHY through ULPI interface
- Eight UARTs with IrDA, 9-bit and ISO 7816 support.
- Ten I<sup>2</sup>C modules with four transmission speeds including high-speed mode
- Four Quad Synchronous Serial Interface modules (QSSI) with bi- and quad-SSI support

The following sections provide more detail on each of these communications functions.

#### 1.3.8.1 Ethernet MAC (see page 1524)

The TM4C129DNCPDT Ethernet Controller consists of a fully integrated media access controller (MAC) with the following features:

- Conforms to the IEEE 802.3 specification
  - 10BASE-T/100BASE-TX IEEE-802.3 compliant
  - Supports 10/100 Mbps data transmission rates
  - Supports full-duplex and half-duplex (CSMA/CD) operation
  - Supports flow control and back pressure
  - Full-featured and enhanced auto-negotiation
  - Supports IEEE 802.1Q VLAN tag detection
- Conforms to IEEE 1588-2002 Timestamp Precision Time Protocol (PTP) protocol and the IEEE 1588-2008 Advanced Timestamp specification
  - Transmit and Receive frame time stamping
  - Precision Time Protocol
  - Flexible pulse per second output
  - Supports coarse and fine correction methods
- Multiple addressing modes
  - Four MAC address filters
  - Programmable 64-bit Hash Filter for multicast address filtering

- Promiscuous mode support
- Processor offloading
  - Programmable insertion (TX) or deletion (RX) of preamble and start-of-frame data
  - Programmable generation (TX) or deletion (RX) of CRC and pad data
  - IP header and hardware checksum checking (IPv4, IPv6, TCP/UDP/ICMP)
- Highly configurable
  - Supports network statistics with RMON/MIB counters
  - Supports Magic Packet and wakeup frames
- Efficient transfers using integrated Direct Memory Access (DMA)
  - Dual-buffer (ring) or linked-list (chained) descriptors
  - Round-robin or fixed priority arbitration between TX/RX
  - Descriptors support up to 8 kB transfer blocks size
  - Programmable interrupts for flexible system implementation
- MII and RMII interface support

### 1.3.8.2 Controller Area Network (CAN) (see page 1473)

Controller Area Network (CAN) is a multicast shared serial-bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or twisted-pair wire. Originally created for automotive purposes, it is now used in many embedded control applications (for example, industrial or medical). Bit rates up to 1 Mbps are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500m).

A transmitter sends a message to all CAN nodes (broadcasting). Each node decides on the basis of the identifier received whether it should process the message. The identifier also determines the priority that the message enjoys in competition for bus access. Each CAN message can transmit from 0 to 8 bytes of user information.

The TM4C129DNCPDT microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects

- Gluelessly attaches to an external CAN transceiver through the CANnTX and CANnRX signals

### 1.3.8.3 Universal Serial Bus (USB) (see page 1697)

Universal Serial Bus (USB) is a serial bus standard designed to allow peripherals to be connected and disconnected using a standardized interface without rebooting the system.

The TM4C129DNCPDT microcontroller has one USB controller that supports high and full speed multi-point communications and complies with the USB 2.0 standard for high-speed function. The USB controller can have three configurations: USB Device, USB Host, and USB On-The-Go (negotiated on-the-go as host or device when connected to other USB-enabled systems). Support for full-speed communication is provided by using the integrated USB PHY or optionally, a high-speed ULPI interface can communicate to an external PHY.

The USB module has the following features:

- Complies with USB-IF (Implementer's Forum) certification standards
- USB 2.0 high-speed (480 Mbps) operation with the integrated ULPI interface communicating with an external PHY
- Link Power Management support which uses link-state awareness to reduce power usage
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- VBUS droop detection and interrupt
- Integrated USB DMA with bus master capability
  - Up to eight RX Endpoint channels and up to eight TX Endpoint channels are available.
  - Each channel can be separately programmed to operate in different modes
  - Incremental burst transfers of 4-, 8-, 16- or unspecified length supported

### 1.3.8.4 UART (see page 1278)

A Universal Asynchronous Receiver/Transmitter (UART) is an integrated circuit used for RS-232C serial communications, containing a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter), each clocked separately.

The TM4C129DNCPDT microcontroller includes eight fully programmable 16C550-type UARTs. Although the functionality is similar to a 16C550 UART, this UART design is not register compatible. The UART can generate individually masked interrupts from the Rx, Tx, modem flow control, modem status, and error conditions. The module generates a single combined interrupt when any of the interrupts are asserted and are unmasked.

The eight UARTs have the following features:

- Programmable baud-rate generator allowing speeds up to 7.5 Mbps for regular speed (divide by 16) and 15 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem functionality available on the following UARTs:
  - UART0 (modem flow control and modem status)
  - UART1 (modem flow control and modem status)
  - UART2 (modem flow control)
  - UART3 (modem flow control)
  - UART4 (modem flow control)
- EIA-485 9-bit support
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level

- Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock

### 1.3.8.5 I<sup>2</sup>C (see page 1392)

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL). The I<sup>2</sup>C bus interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacture.

Each device on the I<sup>2</sup>C bus can be designated as either a master or a slave. I<sup>2</sup>C module supports both sending and receiving data as either a master or a slave and can operate simultaneously as both a master and a slave. Both the I<sup>2</sup>C master and slave can generate interrupts.

The TM4C129DNCPDT microcontroller includes I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both transmitting and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Two 8-entry FIFOs for receive and transmit data
  - FIFOs can be independently assigned to master or slave
- Four transmission speeds:
  - Standard (100 Kbps)
  - Fast-mode (400 Kbps)
  - Fast-mode plus (1 Mbps)
  - High-speed mode (3.33 Mbps)
- Glitch suppression
- SMBus support through software
  - Clock low timeout interrupt
  - Dual slave address capability

- Quick command capability
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
  - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive
  - Ability to execute single data transfers or burst data transfers using the RX and TX FIFOs in the I<sup>2</sup>C

#### 1.3.8.6 QSSI (see page 1343)

Quad Synchronous Serial Interface (QSSI) is a bi-directional communications interface that converts data between parallel and serial. The QSSI module performs serial-to-parallel conversion on data received from a peripheral device, and parallel-to-serial conversion on data transmitted to a peripheral device. The QSSI module can be configured as either a master or slave device. As a slave device, the QSSI module can also be configured to disable its output, which allows a master device to be coupled with multiple slave devices. The TX and RX paths are buffered with separate internal FIFOs.

The QSSI module also includes a programmable bit rate clock divider and prescaler to generate the output serial clock derived from the QSSI module's input clock. Bit rates are generated based on the input clock and the maximum bit rate is determined by the connected peripheral.

The TM4C129DNC PDT microcontroller includes four QSSI modules with the following features:

- Four QSSI channels with Advanced, Bi- and Quad-SSI functionality
- Programmable interface operation for Freescale SPI or Texas Instruments synchronous serial interfaces in Legacy Mode. Support for Freescale interface in Bi- and Quad-SSI mode.
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive

- Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
- Transmit single request asserted when there is space in the FIFO; burst request asserted when four or more entries are available to be written in the FIFO
- Maskable  $\mu$ DMA interrupts for receive and transmit complete
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock.

### 1.3.9 System Integration

The TM4C129DNCPDT microcontroller provides a variety of standard system functions integrated into the device, including:

- Direct Memory Access Controller (DMA)
- System control and clocks including on-chip precision 16-MHz oscillator
- Eight 32-bit timers (each of which can be configured as two 16-bit timers)
- Lower-power battery-backed Hibernation module
- Real-Time Clock in Hibernation module
- Two Watchdog Timers
  - One timer runs off the main oscillator
  - One timer runs off the precision internal oscillator
- Up to 98 GPIOs, depending on configuration
  - Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
  - Independently configurable to 2-, 4-, 8-, 10-, or 12-mA drive capability
  - Up to 4 GPIOs can have 18-mA drive capability

The following sections provide more detail on each of these functions.

#### 1.3.9.1 Direct Memory Access (see page 678)

The TM4C129DNCPDT microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA ( $\mu$ DMA). The  $\mu$ DMA controller provides a way to offload data transfer tasks from the Cortex-M4F processor, allowing for more efficient use of the processor and the available bus bandwidth. The  $\mu$ DMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The  $\mu$ DMA controller provides the following features:

- ARM PrimeCell® 32-channel configurable  $\mu$ DMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes
  - Basic for simple transfer scenarios
  - Ping-pong for continuous data flow

- Scatter-gather for a programmable list of up to 256 arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
  - Independently configured and operated channels
  - Dedicated channels for supported on-chip modules
  - Flexible channel assignments
  - One channel each for receive and transmit path for bidirectional modules
  - Dedicated channel for software-initiated transfers
  - Per-channel configurable priority scheme
  - Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between  $\mu$ DMA controller and the processor core
  - $\mu$ DMA controller access is subordinate to core access
  - RAM striping
  - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment
- Maskable peripheral requests
- Interrupt on transfer completion, with a separate interrupt per channel

### 1.3.9.2 System Control and Clocks (see page 226)

System control determines the overall operation of the device. It provides information about the device, controls power-saving features, controls the clocking of the device and individual peripherals, and handles reset detection and reporting.

- Device identification information: version, part number, SRAM size, Flash memory size, and so on
- Power control
  - On-chip fixed Low Drop-Out (LDO) voltage regulator
  - Hibernation module handles the power-up/down 3.3 V sequencing and control for the core digital logic and analog circuits
  - Low-power options for microcontroller: Sleep and Deep-Sleep modes with clock gating

- Low-power options for on-chip modules: software controls shutdown of individual peripherals and memory
- 3.3-V supply brown-out detection and reporting via interrupt or reset
- Multiple clock sources for microcontroller system clock. The TM4C129DNCPDT microcontroller is clocked by the system clock (SYSCLK) that is distributed to the processor and integrated peripherals after clock gating. The SYSCLK frequency is based on the frequency of the clock source and a divisor factor. A PLL is provided for the generation of system clock frequencies in excess of the reference clock provided. The reference clocks for the PLL are the PIOSC and the main crystal oscillator. The following clock sources are provided to the TM4C129DNCPDT microcontroller:
  - 16-MHz Precision Oscillator (PIOSC)
  - Main Oscillator (MOSC): A frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins.
  - Low Frequency Internal Oscillator (LFIOSC): On-chip resource used during power-saving modes
  - Hibernate RTC oscillator (RTCOSC) clock that can be configured to be the 32.768-kHz external oscillator source from the Hibernation (HIB) module or the HIB Low Frequency clock source (HIB LFIOSC), which is located within the Hibernation Module.
- Flexible reset sources
  - Power-on reset (POR)
  - Reset pin assertion
  - Brown-out reset (BOR) detector alerts to system power drops
  - Software reset
  - Watchdog timer reset
  - Hibernation module event
  - MOSC failure
- 128-bit unique identifier for individual device identification

### 1.3.9.3 Programmable Timers (see page 1072)

Programmable timers can be used to count or time external events that drive the Timer input pins. Each 16/32-bit GPTM block provides two 16-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions and DMA transfers.

The General-Purpose Timer Module (GPTM) contains eight 16/32-bit GPTM blocks with the following functional options:

- Operating modes:

- 16- or 32-bit programmable one-shot timer
- 16- or 32-bit programmable periodic timer
- 16-bit general-purpose timer with an 8-bit prescaler
- 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
- 16-bit input-edge count- or time-capture modes with an 8-bit prescaler
- 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
- The System Clock or a global Alternate Clock (ALTCLK) resource can be used as timer clock source. The global ALTCLK can be:
  - PIOSC
  - Hibernation Module Real-time clock output (RTCOSC)
  - Low-frequency internal oscillator (LFIOSC)
- Count up or down
- Twelve 16/32-bit Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)
- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Dedicated channel for each timer
  - Burst request generated on timer interrupt

#### **1.3.9.4 CCP Pins (see page 1079)**

Capture Compare PWM pins (CCP) can be used by the General-Purpose Timer Module to time/count external events using the CCP pin as an input. Alternatively, the GPTM can generate a simple PWM output on the CCP pin.

The TM4C129DNCPDT microcontroller includes twelve 16/32-bit CCP pins that can be programmed to operate in the following modes:

- Capture: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer captures and stores the current timer value when a programmed event occurs.

- Compare: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer compares the current value with a stored value and generates an interrupt when a match occurs.
- PWM: The GP Timer is incremented/decremented by the system clock. A PWM signal is generated based on a match between the counter value and a value stored in a match register and is output on the CCP pin.

#### 1.3.9.5 Hibernation Module (HIB) (see page 531)

The Hibernation module provides logic to switch power off to the main processor and peripherals and to wake on external or time-based events. The Hibernation module includes power-sequencing logic and has the following features:

- 32-bit real-time seconds counter (RTC) with 1/32,768 second resolution and a 15-bit sub-seconds counter
  - 32-bit RTC seconds match register and a 15-bit sub seconds match for timed wake-up and interrupt generation with 1/32,768 second resolution
  - RTC predivider trim for making fine adjustments to the clock rate
- Hardware Calendar Function
  - Year, Month, Day, Day of Week, Hours, Minutes, Seconds
  - Four-year leap compensation
  - 24-hour or AM/PM configuration
- Two mechanisms for power control
  - System power control using discrete external regulator
  - On-chip power control using internal switches under register control
- $V_{DD}$  supplies power when valid, even if  $V_{BAT} > V_{DD}$
- Dedicated pin for waking using an external signal
- Capability to configure external reset (RST) pin and/or up to four GPIO port pins as wake source, with programmable wake level
- Tamper Functionality
  - Support for four tamper inputs
  - Configurable level, weak pull-up, and glitch filter
  - Configurable tamper event response
  - Logging of up to four tamper events
  - Optional BBRAM erase on tamper detection
  - Tamper wake from hibernate capability

- Hibernation clock input failure detect with a switch to the internal oscillator on detection
- RTC operational and hibernation memory valid as long as  $V_{DD}$  or  $V_{BAT}$  is valid
- Low-battery detection, signaling, and interrupt generation, with optional wake on low battery
- GPIO pin state can be retained during hibernation
- Clock source from an internal low frequency oscillator (HIB LFIOOSC) or a 32.768-kHz external crystal or oscillator
- Sixteen 32-bit words of battery-backed memory to save state during hibernation
- Programmable interrupts for:
  - RTC match
  - External wake
  - Low battery

#### 1.3.9.6 Watchdog Timers (see page 1145)

A watchdog timer is used to regain control when a system has failed due to a software error or to the failure of an external device to respond in the expected way. The TM4C129DNCPDT Watchdog Timer can generate an interrupt, a non-maskable interrupt, or a reset when a time-out value is reached. In addition, the Watchdog Timer is ARM FiRM-compliant and can be configured to generate an interrupt to the microcontroller on its first time-out, and to generate a reset signal on its second timeout. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

The TM4C129DNCPDT microcontroller has two Watchdog Timer modules: Watchdog Timer 0 uses the system clock for its timer clock; Watchdog Timer 1 uses the PIOSC as its timer clock. The Watchdog Timer module has the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

#### 1.3.9.7 Programmable GPIOs (see page 742)

General-purpose input/output (GPIO) pins offer flexibility for a variety of connections. The TM4C129DNCPDT GPIO module is comprised of 15 physical GPIO blocks, each corresponding to an individual GPIO port. The GPIO module is FiRM-compliant (compliant to the ARM Foundation IP for Real-Time Microcontrollers specification) and supports 0-98 programmable input/output pins. The number of GPIOs available depends on the peripherals being used (see “Signal Tables” on page 1825 for the signals available to each GPIO pin).

- Up to 98 GPIOs, depending on configuration

- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 3.3-V-tolerant in input configuration
- Advanced High Performance Bus accesses all ports:
  - Ports A-H and J; Ports K-N and P-Q
- Fast toggle capable of a change every clock cycle for ports on AHB
- Programmable control for GPIO interrupts
  - Interrupt generation masking
  - Edge-triggered on rising, falling, or both
  - Level-sensitive on High or Low values
  - Per-pin interrupts available on Port P and Port Q
- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence or a  $\mu$ DMA transfer
- Pin state can be retained during Hibernation mode; pins on port P can be programmed to wake on level in Hibernation mode
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
  - Weak pull-up or pull-down resistors
  - 2-mA, 4-mA, 6-mA, 8-mA, 10-mA and 12-mA pad drive for digital communication; up to four pads can sink 18-mA for high-current applications
  - Slew rate control for 8-mA, 10-mA and 12-mA pad drive
  - Open drain enables
  - Digital input enables

### 1.3.10 Advanced Motion Control

The TM4C129DNCPDT microcontroller provides motion control functions integrated into the device, including:

- Eight advanced PWM outputs for motion and energy applications
- Four fault inputs to promote low-latency shutdown
- One Quadrature Encoder Input (QEI)

The following provides more detail on these motion control functions.

### 1.3.10.1 PWM (see page 1722)

The TM4C129DNCPDT microcontroller contains one PWM module, with four PWM generator blocks and a control block, for a total of 8 PWM outputs. Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control. The TM4C129DNCPDT PWM module consists of four PWM generator block and a control block. Each PWM generator block contains one timer (16-bit down or up/down counter), two comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector. Each PWM generator block produces two PWM signals that can either be independent signals or a single pair of complementary signals with dead-band delays inserted.

Each PWM generator has the following features:

- Four fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled
- One 16-bit counter
  - Runs in Down or Up/Down mode
  - Output frequency controlled by a 16-bit load value
  - Load value updates can be synchronized
  - Produces output signals at zero and load value
- Two PWM comparators
  - Comparator value updates can be synchronized
  - Produces output signals on match
- PWM signal generator
  - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
  - Produces two independent PWM signals
- Dead-band generator
  - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
  - Can be bypassed, leaving input PWM signals unmodified
- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal

- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Extended PWM synchronization of timer/comparator updates across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended PWM fault handling, with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

#### 1.3.10.2 QEI (see page 1801)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, the position, direction of rotation, and speed can be tracked. In addition, a third channel, or index signal, can be used to reset the position counter. The TM4C129DNCPDT quadrature encoder with index (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel. The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 30 MHz for a 120-MHz system).

The TM4C129DNCPDT microcontroller includes one QEI module providing control of one motor with the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
  - Index pulse
  - Velocity-timer expiration
  - Direction change
  - Quadrature error detection

#### 1.3.11 Analog

The TM4C129DNCPDT microcontroller provides analog functions integrated into the device, including:

- Two 12-bit Analog-to-Digital Converters (ADC), with a total of 20 analog input channels and each with a sample rate of two million samples/second
- Three analog comparators

- On-chip voltage regulator

The following provides more detail on these analog functions.

#### 1.3.11.1 ADC (see page 1170)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. The TM4C129DNCPDT ADC module features 12-bit conversion resolution and supports 20 input channels plus an internal temperature sensor. Four buffered sample sequencers allow rapid sampling of up to 20 analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. Each ADC module has a digital comparator function that allows the conversion value to be diverted to a comparison unit that provides eight digital comparators.

The TM4C129DNCPDT microcontroller provides two ADC modules, each with the following features:

- 20 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of two million samples/second
- Optional, programmable phase delay
- Sample and hold window programmability
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - PWM
  - GPIO
- Hardware averaging of up to 64 samples
- Eight digital comparators
- Converter uses signals VREFA+ and GNDA as the voltage reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Dedicated channel for each sample sequencer

- ADC module uses burst requests for DMA
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate ADC clock

### 1.3.11.2 Analog Comparators (see page 1706)

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result. The TM4C129DNCPDT microcontroller provides three independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The TM4C129DNCPDT microcontroller provides three independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

### 1.3.12 JTAG and ARM Serial Wire Debug (see page 213)

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging. Texas Instruments replaces the ARM SW-DP and JTAG-DP with the ARM Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module providing all the normal JTAG debug and test functionality plus real-time access to system memory without halting the core or requiring any target resident code. The SWJ-DP interface has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, and EXTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
  - Serial Wire JTAG Debug Port (SWJ-DP)

- Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
- Data Watchpoint and Trace (DWT) unit for implementing watchpoints, trigger resources, and system profiling
- Instrumentation Trace Macrocell (ITM) for support of printf style debugging
- Embedded Trace Macrocell (ETM) for instruction trace capture
- Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

### 1.3.13 Packaging and Temperature

- 128-pin RoHS-compliant TQFP package
- Industrial (-40°C to 85°C) ambient temperature range
- Extended (-40°C to 105°C) ambient temperature range

## 1.4 TM4C129DNCPDT Microcontroller Hardware Details

Details on the pins and package can be found in the following sections:

- “Pin Diagram” on page 1824
- “Signal Tables” on page 1825
- “Electrical Characteristics” on page 1874
- “Package Information” on page 1941

## 1.5 Kits

The Tiva™ C Series provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware and comprehensive documentation including hardware design files
- Evaluation Kits provide a low-cost and effective means of evaluating TM4C129DNCPDT microcontrollers before purchase
- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box

See the Tiva series website at <http://www.ti.com/tiva-c> for the latest tools available, or ask your distributor.

## 1.6 Support Information

For support on Tiva™ C Series products, contact the [TI Worldwide Product Information Center](#) nearest you.

## 2 The Cortex-M4F Processor

The ARM® Cortex™-M4F processor provides a high-performance, low-cost platform that meets the system requirements of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts. Features include:

- 32-bit ARM® Cortex™-M4F architecture optimized for small-footprint embedded applications
- 120-MHz operation; 150 DMIPS performance
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- 16-bit SIMD vector processing unit
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast digital-signal-processing orientated multiply accumulate
- Saturating arithmetic for signal processing
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing
- Migration from the ARM7™ processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage up to specific frequencies; see “Internal Memory” on page 600 for more information.
- Ultra-low power consumption with integrated sleep modes

The Tiva™ C Series microcontrollers builds on this core to bring high-performance 32-bit computing to cost-conscious applications requiring significant control processing and connectivity capabilities such as:

- Low power, hand-held smart devices
- Gaming equipment
- Network appliances and switches
- Home and commercial site monitoring and control
- Electronic point-of-sale (POS) machines
- Motion control
- Medical instrumentation
- Remote connectivity and monitoring
- Test and measurement equipment
- Factory automation
- Fire and security
- Smart Energy/Smart Grid solutions
- Intelligent lighting control
- Transportation

This chapter provides information on the Tiva™ C Series implementation of the Cortex-M4F processor, including the programming model, the memory model, the exception model, fault handling, and power management.

For technical details on the instruction set, see the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)).

## 2.1 Block Diagram

The Cortex-M4F processor is built on a high-performance processor core, with a 3-stage pipeline Harvard architecture, making it ideal for demanding embedded applications. The processor delivers exceptional power efficiency through an efficient instruction set and extensively optimized design, providing high-end processing hardware including IEEE754-compliant single-precision floating-point computation, a range of single-cycle and SIMD multiplication and multiply-with-accumulate capabilities, saturating arithmetic and dedicated hardware division.

To facilitate the design of cost-sensitive devices, the Cortex-M4F processor implements tightly coupled system components that reduce processor area while significantly improving interrupt handling and system debug capabilities. The Cortex-M4F processor implements a version of the Thumb® instruction set based on Thumb-2 technology, ensuring high code density and reduced program memory requirements. The Cortex-M4F instruction set provides the exceptional performance expected of a modern 32-bit architecture, with the high code density of 8-bit and 16-bit microcontrollers.

The Cortex-M4F processor closely integrates a nested interrupt controller (NVIC), to deliver industry-leading interrupt performance. The TM4C129DNCPDT NVIC includes a non-maskable interrupt (NMI) and provides eight interrupt priority levels. The tight integration of the processor core and NVIC provides fast execution of interrupt service routines (ISRs), dramatically reducing interrupt latency. The hardware stacking of registers and the ability to suspend load-multiple and store-multiple operations further reduce interrupt latency. Interrupt handlers do not require any assembler stubs which removes code overhead from the ISRs. Tail-chaining optimization also significantly reduces the overhead when switching from one ISR to another. To optimize low-power designs, the NVIC integrates with the sleep modes, including Deep-sleep mode, which enables the entire device to be rapidly powered down.

Figure 2-1. CPU Block Diagram

## 2.2 Overview

### 2.2.1 System-Level Interface

The Cortex-M4F processor provides multiple interfaces using AMBA® technology to provide high-speed, low-latency memory accesses. The core supports unaligned data accesses and implements atomic bit manipulation that enables faster peripheral controls, system spinlocks, and thread-safe Boolean data handling.

The Cortex-M4F processor has a memory protection unit (MPU) that provides fine-grain memory control, enabling applications to implement security privilege levels and separate code, data and stack on a task-by-task basis.

### 2.2.2 Integrated Configurable Debug

The Cortex-M4F processor implements a complete hardware debug solution, providing high system visibility of the processor and memory through either a traditional JTAG port or a 2-pin Serial Wire Debug (SWD) port that is ideal for microcontrollers and other small package devices. The Tiva™ C Series implementation replaces the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module. See the *ARM® Debug Interface V5 Architecture Specification* for details on SWJ-DP.

For system trace, the processor integrates an Instrumentation Trace Macrocell (ITM) alongside data watchpoints and a profiling unit. To enable simple and cost-effective profiling of the system trace events, a Serial Wire Viewer (SWV) can export a stream of software-generated messages, data trace, and profiling information through a single pin.

The Embedded Trace Macrocell (ETM) delivers unrivaled instruction trace capture in an area smaller than traditional trace units, enabling full instruction trace. For more details on the ARM ETM, see the *ARM® Embedded Trace Macrocell Architecture Specification*.

The Flash Patch and Breakpoint Unit (FPB) provides up to eight hardware breakpoint comparators that debuggers can use. The comparators in the FPB also provide remap functions for up to eight words of program code in the code memory region. This FPB enables applications stored in a read-only area of Flash memory to be patched in another area of on-chip SRAM or Flash memory. If a patch is required, the application programs the FPB to remap a number of addresses. When those addresses are accessed, the accesses are redirected to a remap table specified in the FPB configuration.

For more information on the Cortex-M4F debug capabilities, see the *ARM® Debug Interface V5 Architecture Specification*.

### 2.2.3 Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the Cortex-M4F trace data from the ITM, and an off-chip Trace Port Analyzer, as shown in Figure 2-2 on page 88.

**Figure 2-2. TPIU Block Diagram**

### 2.2.4 Cortex-M4F System Component Details

The Cortex-M4F includes the following system components:

- SysTick

A 24-bit count-down timer that can be used as a Real-Time Operating System (RTOS) tick timer or as a simple counter (see “System Timer (SysTick)” on page 141).

- Nested Vectored Interrupt Controller (NVIC)

An embedded interrupt controller that supports low latency interrupt processing (see “Nested Vectored Interrupt Controller (NVIC)” on page 142).

- System Control Block (SCB)

The programming model interface to the processor. The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions (see “System Control Block (SCB)” on page 143).

- Memory Protection Unit (MPU)

Improves system reliability by defining the memory attributes for different memory regions. The MPU provides up to eight different regions and an optional predefined background region (see “Memory Protection Unit (MPU)” on page 143).

- Floating-Point Unit (FPU)

Fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square-root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions (see “Floating-Point Unit (FPU)” on page 148).

## 2.3 Programming Model

This section describes the Cortex-M4F programming model. In addition to the individual core register descriptions, information about the processor modes and privilege levels for software execution and stacks is included.

### 2.3.1 Processor Mode and Privilege Levels for Software Execution

The Cortex-M4F has two modes of operation:

- Thread mode

Used to execute application software. The processor enters Thread mode when it comes out of reset.

- Handler mode

Used to handle exceptions. When the processor has finished exception processing, it returns to Thread mode.

In addition, the Cortex-M4F has two privilege levels:

- Unprivileged

In this mode, software has the following restrictions:

- Limited access to the MSR and MRS instructions and no use of the CPS instruction
- No access to the system timer, NVIC, or system control block
- Possibly restricted access to memory or peripherals

- Privileged

In this mode, software can use all the instructions and has access to all resources.

In Thread mode, the **CONTROL** register (see page 104) controls whether software execution is privileged or unprivileged. In Handler mode, software execution is always privileged.

Only privileged software can write to the **CONTROL** register to change the privilege level for software execution in Thread mode. Unprivileged software can use the SVC instruction to make a supervisor call to transfer control to privileged software.

### 2.3.2 Stacks

The processor uses a full descending stack, meaning that the stack pointer indicates the last stacked item on the memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory location. The processor implements two stacks: the main stack and the process stack, with a pointer for each held in independent registers (see the **SP** register on page 94).

In Thread mode, the **CONTROL** register (see page 104) controls whether the processor uses the main stack or the process stack. In Handler mode, the processor always uses the main stack. The options for processor operations are shown in Table 2-1 on page 90.

**Table 2-1. Summary of Processor Mode, Privilege Level, and Stack Use**

| Processor Mode | Use                | Privilege Level                         | Stack Used                               |
|----------------|--------------------|-----------------------------------------|------------------------------------------|
| Thread         | Applications       | Privileged or unprivileged <sup>a</sup> | Main stack or process stack <sup>a</sup> |
| Handler        | Exception handlers | Always privileged                       | Main stack                               |

a. See **CONTROL** (page 104).

### 2.3.3 Register Map

Figure 2-3 on page 91 shows the Cortex-M4F register set. Table 2-2 on page 91 lists the Core registers. The core registers are not memory mapped and are accessed by register name, so the base address is n/a (not applicable) and there is no offset.

Figure 2-3. Cortex-M4F Register Set

Table 2-2. Processor Register Map

| Offset | Name | Type | Reset | Description                        | See page |
|--------|------|------|-------|------------------------------------|----------|
| -      | R0   | RW   | -     | Cortex General-Purpose Register 0  | 93       |
| -      | R1   | RW   | -     | Cortex General-Purpose Register 1  | 93       |
| -      | R2   | RW   | -     | Cortex General-Purpose Register 2  | 93       |
| -      | R3   | RW   | -     | Cortex General-Purpose Register 3  | 93       |
| -      | R4   | RW   | -     | Cortex General-Purpose Register 4  | 93       |
| -      | R5   | RW   | -     | Cortex General-Purpose Register 5  | 93       |
| -      | R6   | RW   | -     | Cortex General-Purpose Register 6  | 93       |
| -      | R7   | RW   | -     | Cortex General-Purpose Register 7  | 93       |
| -      | R8   | RW   | -     | Cortex General-Purpose Register 8  | 93       |
| -      | R9   | RW   | -     | Cortex General-Purpose Register 9  | 93       |
| -      | R10  | RW   | -     | Cortex General-Purpose Register 10 | 93       |
| -      | R11  | RW   | -     | Cortex General-Purpose Register 11 | 93       |

Table 2-2. Processor Register Map (*continued*)

| Offset | Name      | Type | Reset       | Description                        | See page |
|--------|-----------|------|-------------|------------------------------------|----------|
| -      | R12       | RW   | -           | Cortex General-Purpose Register 12 | 93       |
| -      | SP        | RW   | -           | Stack Pointer                      | 94       |
| -      | LR        | RW   | 0xFFFF.FFFF | Link Register                      | 95       |
| -      | PC        | RW   | -           | Program Counter                    | 96       |
| -      | PSR       | RW   | 0x0100.0000 | Program Status Register            | 97       |
| -      | PRIMASK   | RW   | 0x0000.0000 | Priority Mask Register             | 101      |
| -      | FAULTMASK | RW   | 0x0000.0000 | Fault Mask Register                | 102      |
| -      | BASEPRI   | RW   | 0x0000.0000 | Base Priority Mask Register        | 103      |
| -      | CONTROL   | RW   | 0x0000.0000 | Control Register                   | 104      |
| -      | FPSC      | RW   | -           | Floating-Point Status Control      | 106      |

### 2.3.4 Register Descriptions

This section lists and describes the Cortex-M4F registers, in the order shown in Figure 2-3 on page 91. The core registers are not memory mapped and are accessed by register name rather than offset.

**Note:** The register type shown in the register descriptions refers to type during program execution in Thread mode and Handler mode. Debug access can differ.

**Register 1: Cortex General-Purpose Register 0 (R0)**

**Register 2: Cortex General-Purpose Register 1 (R1)**

**Register 3: Cortex General-Purpose Register 2 (R2)**

**Register 4: Cortex General-Purpose Register 3 (R3)**

**Register 5: Cortex General-Purpose Register 4 (R4)**

**Register 6: Cortex General-Purpose Register 5 (R5)**

**Register 7: Cortex General-Purpose Register 6 (R6)**

**Register 8: Cortex General-Purpose Register 7 (R7)**

**Register 9: Cortex General-Purpose Register 8 (R8)**

**Register 10: Cortex General-Purpose Register 9 (R9)**

**Register 11: Cortex General-Purpose Register 10 (R10)**

**Register 12: Cortex General-Purpose Register 11 (R11)**

**Register 13: Cortex General-Purpose Register 12 (R12)**

The **Rn** registers are 32-bit general-purpose registers for data operations and can be accessed from either privileged or unprivileged mode.

#### Cortex General-Purpose Register 0 (R0)

Type RW, reset -

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|       | 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|       | DATA |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Type  | RW   | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW |
| Reset | -    | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |
|       | 15   | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|       | DATA |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Type  | RW   | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW |
| Reset | -    | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |

| Bit/Field | Name | Type | Reset | Description    |
|-----------|------|------|-------|----------------|
| 31:0      | DATA | RW   | -     | Register data. |

Register 14: Stack Pointer (SP)

The **Stack Pointer (SP)** is register R13. In Thread mode, the function of this register changes depending on the ASP bit in the **Control Register (CONTROL)** register. When the ASP bit is clear, this register is the **Main Stack Pointer (MSP)**. When the ASP bit is set, this register is the **Process Stack Pointer (PSP)**. On reset, the ASP bit is clear, and the processor loads the **MSP** with the value from address 0x0000.0000. The **MSP** can only be accessed in privileged mode; the **PSP** can be accessed in either privileged or unprivileged mode.

Stack Pointer (SP)

Type RW, reset -

| Bit/Field | Name | Type | Reset | Description                                     |
|-----------|------|------|-------|-------------------------------------------------|
| 31:0      | SP   | RW   | -     | This field is the address of the stack pointer. |

**Register 15: Link Register (LR)**

The **Link Register (LR)** is register R14, and it stores the return information for subroutines, function calls, and exceptions. The Link Register can be accessed from either privileged or unprivileged mode.

EXC\_RETURN is loaded into the **LR** on exception entry. See Table 2-10 on page 129 for the values and description.

**Link Register (LR)**

Type RW, reset 0xFFFF.FFFF

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|       | 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|       | LINK |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Type  | RW   | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW |
| Reset | 1    | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  |
|       | 15   | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|       | LINK |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Type  | RW   | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW |
| Reset | 1    | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  |

| Bit/Field | Name | Type | Reset       | Description                       |
|-----------|------|------|-------------|-----------------------------------|
| 31:0      | LINK | RW   | 0xFFFF.FFFF | This field is the return address. |

Register 16: Program Counter (PC)

The **Program Counter (PC)** is register R15, and it contains the current program address. On reset, the processor loads the **PC** with the value of the reset vector, which is at address 0x0000.0004. Bit 0 of the reset vector is loaded into the THUMB bit of the **EPSR** at reset and must be 1. The **PC** register can be accessed in either privileged or unprivileged mode.

Program Counter (PC)

Type RW, reset -

| Bit/Field | Name | Type | Reset | Description                                |
|-----------|------|------|-------|--------------------------------------------|
| 31:0      | PC   | RW   | -     | This field is the current program address. |

## Register 17: Program Status Register (PSR)

**Note:** This register is also referred to as **xPSR**.

The **Program Status Register (PSR)** has three functions, and the register bits are assigned to the different functions:

- **Application Program Status Register (APSR)**, bits 31:27, bits 19:16
- **Execution Program Status Register (EPSR)**, bits 26:24, 15:10
- **Interrupt Program Status Register (IPSR)**, bits 7:0

The **PSR**, **IPSR**, and **EPSR** registers can only be accessed in privileged mode; the **APSR** register can be accessed in either privileged or unprivileged mode.

**APSR** contains the current state of the condition flags from previous instruction executions.

**EPSR** contains the Thumb state bit and the execution state bits for the If-Then (IT) instruction or the Interruptible-Continuable Instruction (ICI) field for an interrupted load multiple or store multiple instruction. Attempts to read the **EPSR** directly through application software using the MSR instruction always return zero. Attempts to write the **EPSR** using the MSR instruction in application software are always ignored. Fault handlers can examine the **EPSR** value in the stacked **PSR** to determine the operation that faulted (see “Exception Entry and Return” on page 126).

**IPSR** contains the exception type number of the current Interrupt Service Routine (ISR).

These registers can be accessed individually or as a combination of any two or all three registers, using the register name as an argument to the MSR or MRS instructions. For example, all of the registers can be read using **PSR** with the MRS instruction, or **APSR** only can be written to using **APSR** with the MSR instruction. page 97 shows the possible register combinations for the **PSR**. See the MRS and MSR instruction descriptions in the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number ARM DUI 0553A)* for more information about how to access the program status registers.

**Table 2-3. PSR Register Combinations**

| Register     | Type               | Combination                                 |
|--------------|--------------------|---------------------------------------------|
| <b>PSR</b>   | RW <sup>a, b</sup> | <b>APSR</b> , <b>EPSR</b> , and <b>IPSR</b> |
| <b>IEPSR</b> | RO                 | <b>EPSR</b> and <b>IPSR</b>                 |
| <b>IAPSR</b> | RW <sup>a</sup>    | <b>APSR</b> and <b>IPSR</b>                 |
| <b>EAPSR</b> | RW <sup>b</sup>    | <b>APSR</b> and <b>EPSR</b>                 |

a. The processor ignores writes to the **IPSR** bits.

b. Reads of the **EPSR** bits return zero, and the processor ignores writes to these bits.

### Program Status Register (PSR)

Type RW, reset 0x0100.0000

|       |          |    |    |    |    |          |    |       |          |        |    |    |    |    |    |    |

## Register 18: Priority Mask Register (PRIMASK)

The **PRIMASK** register prevents activation of all exceptions with programmable priority. Reset, non-maskable interrupt (NMI), and hard fault are the only exceptions with fixed priority. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The MSR and MRS instructions are used to access the **PRIMASK** register, and the CPS instruction may be used to change the value of the **PRIMASK** register. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number ARM DUI 0553A)* for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 119.

**Register 19: Fault Mask Register (FAULTMASK)**

The **FAULTMASK** register prevents activation of all exceptions except for the Non-Maskable Interrupt (NMI). Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The MSR and MRS instructions are used to access the **FAULTMASK** register, and the CPS instruction may be used to change the value of the **FAULTMASK** register. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)) for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 119.

## Value Description

|   |                                                           |
|---|-----------------------------------------------------------|
| 1 | Prevents the activation of all exceptions except for NMI. |
| 0 | No effect.                                                |

The processor clears the FAULTMASK bit on exit from any exception handler except the NMI handler.

## Register 20: Base Priority Mask Register (BASEPRI)

The **BASEPRI** register defines the minimum priority for exception processing. When **BASEPRI** is set to a nonzero value, it prevents the activation of all exceptions with the same or lower priority level as the **BASEPRI** value. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. For more information on exception priority levels, see “Exception Types” on page 119.

### Base Priority Mask Register (BASEPRI)

Type RW, reset 0x0000.0000

## Register 21: Control Register (CONTROL)

The **CONTROL** register controls the stack used and the privilege level for software execution when the processor is in Thread mode, and indicates whether the FPU state is active. This register is only accessible in privileged mode.

Handler mode always uses the **MSP**, so the processor ignores explicit writes to the ASP bit of the **CONTROL** register when in Handler mode. The exception entry and return mechanisms automatically update the **CONTROL** register based on the EXC\_RETURN value (see Table 2-10 on page 129). In an OS environment, threads running in Thread mode should use the process stack and the kernel and exception handlers should use the main stack. By default, Thread mode uses the **MSP**. To switch the stack pointer used in Thread mode to the **PSP**, either use the MSR instruction to set the ASP bit, as detailed in the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)), or perform an exception return to Thread mode with the appropriate EXC\_RETURN value, as shown in Table 2-10 on page 129.

**Note:** When changing the stack pointer, software must use an ISB instruction immediately after the MSR instruction, ensuring that instructions after the ISB execute use the new stack pointer. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)).

### Control Register (CONTROL)

Type RW, reset 0x0000.0000

The Cortex-M4F uses this bit to determine whether to preserve floating-point state when processing an exception.

**Important:** Two bits control when FPCA can be enabled: the ASPEN bit in the **Floating-Point Context Control (FPCC)** register and the DISFPCA bit in the **Auxiliary Control (ACTLR)** register.

## Register 22: Floating-Point Status Control (FPSC)

The **FPSC** register provides all necessary user-level control of the floating-point system.

### Floating-Point Status Control (FPSC)

Type RW, reset -

### 2.3.5 Exceptions and Interrupts

The Cortex-M4F processor supports interrupts and system exceptions. The processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions. An exception changes the normal flow of software control. The processor uses Handler mode to handle all exceptions except for reset. See “Exception Entry and Return” on page 126 for more information.

The NVIC registers control interrupt handling. See “Nested Vectored Interrupt Controller (NVIC)” on page 142 for more information.

### 2.3.6 Data Types

The Cortex-M4F supports 32-bit words, 16-bit halfwords, and 8-bit bytes. The processor also supports 64-bit data transfer instructions. All instruction and data memory accesses are little endian. See “Memory Regions, Types and Attributes” on page 111 for more information.

## 2.4 Memory Model

This section describes the processor memory map, the behavior of memory accesses, and the bit-banding features. The processor has a fixed memory map that provides up to 4 GB of addressable memory.

The memory map for the TM4C129DNCPTD controller is provided in Table 2-4 on page 108. In this manual, register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map.

The regions for SRAM and peripherals include bit-band regions. Bit-banding provides atomic operations to bit data (see “Bit-Banding” on page 114).

The processor reserves regions of the Private peripheral bus (PPB) address range for core peripheral registers (see “Cortex-M4 Peripherals” on page 140).

**Note:** Within the memory map, attempts to read or write addresses in reserved spaces result in a bus fault. In addition, attempts to write addresses in the flash range also result in a bus fault.

**Table 2-4. Memory Map**

### 2.4.1 Memory Regions, Types and Attributes

The memory map and the programming of the MPU split the memory map into regions. Each region has a defined memory type, and some regions have additional memory attributes. The memory type and attributes determine the behavior of accesses to the region.

The memory types are:

- Normal: The processor can re-order transactions for efficiency and perform speculative reads.
- Device: The processor preserves transaction order relative to other transactions to Device or Strongly Ordered memory.
- Strongly Ordered: The processor preserves transaction order relative to all other transactions.

The different ordering requirements for Device and Strongly Ordered memory mean that the memory system can buffer a write to Device memory but must not buffer a write to Strongly Ordered memory.

An additional memory attribute is Execute Never (XN), which means the processor prevents instruction accesses. A fault exception is generated only on execution of an instruction executed from an XN region.

## 2.4.2 Memory System Ordering of Memory Accesses

For most memory accesses caused by explicit memory access instructions, the memory system does not guarantee that the order in which the accesses complete matches the program order of the instructions, providing the order does not affect the behavior of the instruction sequence. Normally, if correct program execution depends on two memory accesses completing in program order, software must insert a memory barrier instruction between the memory access instructions (see “Software Ordering of Memory Accesses” on page 113).

However, the memory system does guarantee ordering of accesses to Device and Strongly Ordered memory. For two memory access instructions A1 and A2, if both A1 and A2 are accesses to either Device or Strongly Ordered memory, and if A1 occurs before A2 in program order, A1 is always observed before A2.

## 2.4.3 Behavior of Memory Accesses

Table 2-5 on page 112 shows the behavior of accesses to each region in the memory map. See “Memory Regions, Types and Attributes” on page 111 for more information on memory types and the XN attribute. Tiva™ C Series devices may have reserved memory areas within the address ranges shown below (refer to Table 2-4 on page 108 for more information).

**Table 2-5. Memory Access Behavior**

| Address Range             | Memory Region          | Memory Type      | Execute Never (XN) | Description                                                                                                                                           |
|---------------------------|------------------------|------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0000.0000 - 0x1FFF.FFFF | Code                   | Normal           | -                  | This executable region is for program code. Data can also be stored here.                                                                             |
| 0x2000.0000 - 0x3FFF.FFFF | SRAM                   | Normal           | -                  | This executable region is for data. Code can also be stored here. This region includes bit band and bit band alias areas (see Table 2-6 on page 114). |
| 0x4000.0000 - 0x5FFF.FFFF | Peripheral             | Device           | XN                 | This region includes bit band and bit band alias areas (see Table 2-7 on page 114).                                                                   |
| 0x6000.0000 - 0x9FFF.FFFF | External RAM           | Normal           | -                  | This executable region is for data.                                                                                                                   |
| 0xA000.0000 - 0xDFFF.FFFF | External device        | Device           | XN                 | This region is for external device memory.                                                                                                            |
| 0xE000.0000- 0xE00F.FFFF  | Private peripheral bus | Strongly Ordered | XN                 | This region includes the NVIC, system timer, and system control block.                                                                                |
| 0xE010.0000- 0xFFFF.FFFF  | Reserved               | -                | -                  | -                                                                                                                                                     |

The Code, SRAM, and external RAM regions can hold programs. However, it is recommended that programs always use the Code region because the Cortex-M4F has separate buses that can perform instruction fetches and data accesses simultaneously.

The MPU can override the default memory access behavior described in this section. For more information, see “Memory Protection Unit (MPU)” on page 143.

The Cortex-M4F prefetches instructions ahead of execution and speculatively prefetches from branch target addresses.

## 2.4.4 Software Ordering of Memory Accesses

The order of instructions in the program flow does not always guarantee the order of the corresponding memory transactions for the following reasons:

- The processor can reorder some memory accesses to improve efficiency, providing this does not affect the behavior of the instruction sequence.
- The processor has multiple bus interfaces.
- Memory or devices in the memory map have different wait states.
- Some memory accesses are buffered or speculative.

“Memory System Ordering of Memory Accesses” on page 112 describes the cases where the memory system guarantees the order of memory accesses. Otherwise, if the order of memory accesses is critical, software must include memory barrier instructions to force that ordering. The Cortex-M4F has the following memory barrier instructions:

- The Data Memory Barrier (DMB) instruction ensures that outstanding memory transactions complete before subsequent memory transactions.
- The Data Synchronization Barrier (DSB) instruction ensures that outstanding memory transactions complete before subsequent instructions execute.
- The Instruction Synchronization Barrier (ISB) instruction ensures that the effect of all completed memory transactions is recognizable by subsequent instructions.

Memory barrier instructions can be used in the following situations:

- MPU programming
  - If the MPU settings are changed and the change must be effective on the very next instruction, use a DSB instruction to ensure the effect of the MPU takes place immediately at the end of context switching.
  - Use an ISB instruction to ensure the new MPU setting takes effect immediately after programming the MPU region or regions, if the MPU configuration code was accessed using a branch or call. If the MPU configuration code is entered using exception mechanisms, then an ISB instruction is not required.
- Vector table

If the program changes an entry in the vector table and then enables the corresponding exception, use a DMB instruction between the operations. The DMB instruction ensures that if the exception is taken immediately after being enabled, the processor uses the new exception vector.
- Self-modifying code

If a program contains self-modifying code, use an ISB instruction immediately after the code modification in the program. The ISB instruction ensures subsequent instruction execution uses the updated program.
- Memory map switching

If the system contains a memory map switching mechanism, use a DSB instruction after switching the memory map in the program. The DSB instruction ensures subsequent instruction execution uses the updated memory map.

- Dynamic exception priority change

When an exception priority has to change when the exception is pending or active, use DSB instructions after the change. The change then takes effect on completion of the DSB instruction.

Memory accesses to Strongly Ordered memory, such as the System Control Block, do not require the use of DMB instructions.

For more information on the memory barrier instructions, see the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)).

## 2.4.5 Bit-Banding

A bit-band region maps each word in a bit-band alias region to a single bit in the bit-band region. The bit-band regions occupy the lowest 1 MB of the SRAM and peripheral memory regions. Accesses to the 32-MB SRAM alias region map to the 1-MB SRAM bit-band region, as shown in Table 2-6 on page 114. Accesses to the 32-MB peripheral alias region map to the 1-MB peripheral bit-band region, as shown in Table 2-7 on page 114. For the specific address range of the bit-band regions, see Table 2-4 on page 108.

**Note:** A word access to the SRAM or the peripheral bit-band alias region maps to a single bit in the SRAM or peripheral bit-band region.

A word access to a bit band address results in a word access to the underlying memory, and similarly for halfword and byte accesses. This allows bit band accesses to match the access requirements of the underlying peripheral.

**Table 2-6. SRAM Memory Bit-Banding Regions**

| Address Range |             | Memory Region        | Instruction and Data Accesses                                                                                                                             |
|---------------|-------------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Start         | End         |                      |                                                                                                                                                           |
| 0x2000.0000   | 0x2006.FFFF | SRAM bit-band region | Direct accesses to this memory range behave as SRAM memory accesses, but this region is also bit addressable through bit-band alias.                      |
| 0x2200.0000   | 0x2234.FFFF | SRAM bit-band alias  | Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not remapped. |

**Table 2-7. Peripheral Memory Bit-Banding Regions**

| Address Range |             | Memory Region              | Instruction and Data Accesses                                                                                                                              |
|---------------|-------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Start         | End         |                            |                                                                                                                                                            |
| 0x4000.0000   | 0x400F.FFFF | Peripheral bit-band region | Direct accesses to this memory range behave as peripheral memory accesses, but this region is also bit addressable through bit-band alias.                 |
| 0x4200.0000   | 0x43FF.FFFF | Peripheral bit-band alias  | Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not permitted. |

The following formula shows how the alias region maps onto the bit-band region:

$$\text{bit\_word\_offset} = (\text{byte\_offset} \times 32) + (\text{bit\_number} \times 4)$$

$\text{bit\_word\_addr} = \text{bit\_band\_base} + \text{bit\_word\_offset}$

where:

$\text{bit\_word\_offset}$

The position of the target bit in the bit-band memory region.

$\text{bit\_word\_addr}$

The address of the word in the alias memory region that maps to the targeted bit.

$\text{bit\_band\_base}$

The starting address of the alias region.

$\text{byte\_offset}$

The number of the byte in the bit-band region that contains the targeted bit.

$\text{bit\_number}$

The bit position, 0-7, of the targeted bit.

Figure 2-4 on page 116 shows examples of bit-band mapping between the SRAM bit-band alias region and the SRAM bit-band region:

- The alias word at 0x23FF.FFE0 maps to bit 0 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFE0 = 0x2200.0000 + (0x000F.FFFF * 32) + (0 * 4)$$

- The alias word at 0x23FF.FFFC maps to bit 7 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFFC = 0x2200.0000 + (0x000F.FFFF * 32) + (7 * 4)$$

- The alias word at 0x2200.0000 maps to bit 0 of the bit-band byte at 0x2000.0000:

$$0x2200.0000 = 0x2200.0000 + (0 * 32) + (0 * 4)$$

- The alias word at 0x2200.001C maps to bit 7 of the bit-band byte at 0x2000.0000:

$$0x2200.001C = 0x2200.0000 + (0 * 32) + (7 * 4)$$

**Figure 2-4. Bit-Band Mapping**

#### 2.4.5.1 Directly Accessing an Alias Region

Writing to a word in the alias region updates a single bit in the bit-band region.

Bit 0 of the value written to a word in the alias region determines the value written to the targeted bit in the bit-band region. Writing a value with bit 0 set writes a 1 to the bit-band bit, and writing a value with bit 0 clear writes a 0 to the bit-band bit.

Bits 31:1 of the alias word have no effect on the bit-band bit. Writing 0x01 has the same effect as writing 0xFF. Writing 0x00 has the same effect as writing 0x0E.

When reading a word in the alias region, 0x0000.0000 indicates that the targeted bit in the bit-band region is clear and 0x0000.0001 indicates that the targeted bit in the bit-band region is set.

#### 2.4.5.2 Directly Accessing a Bit-Band Region

“Behavior of Memory Accesses” on page 112 describes the behavior of direct byte, halfword, or word accesses to the bit-band regions.

#### 2.4.6 Data Storage

The processor views memory as a linear collection of bytes numbered in ascending order from zero. For example, bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word. Data is stored in little-endian format, with the least-significant byte (lsbyte) of a word stored at the lowest-numbered byte, and the most-significant byte (msbyte) stored at the highest-numbered byte. Figure 2-5 on page 117 illustrates how data is stored.

**Figure 2-5. Data Storage**

### 2.4.7 Synchronization Primitives

The Cortex-M4F instruction set includes pairs of synchronization primitives which provide a non-blocking mechanism that a thread or process can use to obtain exclusive access to a memory location. Software can use these primitives to perform a guaranteed read-modify-write memory update sequence or for a semaphore mechanism.

**Note:** The available pairs of synchronization primitives are only available for single processor use and should not be used with multi-processor systems.

A pair of synchronization primitives consists of:

- A Load-Exclusive instruction, which is used to read the value of a memory location and requests exclusive access to that location.
- A Store-Exclusive instruction, which is used to attempt to write to the same memory location and returns a status bit to a register. If this status bit is clear, it indicates that the thread or process gained exclusive access to the memory and the write succeeds; if this status bit is set, it indicates that the thread or process did not gain exclusive access to the memory and no write was performed.

The pairs of Load-Exclusive and Store-Exclusive instructions are:

- The word instructions LDREX and STREX
- The halfword instructions LDREXH and STREXH
- The byte instructions LDREXB and STREXB

Software must use a Load-Exclusive instruction with the corresponding Store-Exclusive instruction.

To perform an exclusive read-modify-write of a memory location, software must:

1. Use a Load-Exclusive instruction to read the value of the location.
2. Modify the value, as required.
3. Use a Store-Exclusive instruction to attempt to write the new value back to the memory location.
4. Test the returned status bit.

If the status bit is clear, the read-modify-write completed successfully. If the status bit is set, no write was performed, which indicates that the value returned at step 1 might be out of date. The software must retry the entire read-modify-write sequence.

Software can use the synchronization primitives to implement a semaphore as follows:

1. Use a Load-Exclusive instruction to read from the semaphore address to check whether the semaphore is free.
2. If the semaphore is free, use a Store-Exclusive to write the claim value to the semaphore address.
3. If the returned status bit from step 2 indicates that the Store-Exclusive succeeded, then the software has claimed the semaphore. However, if the Store-Exclusive failed, another process might have claimed the semaphore after the software performed step 1.

The Cortex-M4F includes an exclusive access monitor that tags the fact that the processor has executed a Load-Exclusive instruction. The processor removes its exclusive access tag if:

- It executes a CLREX instruction.
- It executes a Store-Exclusive instruction, regardless of whether the write succeeds.
- An exception occurs, which means the processor can resolve semaphore conflicts between different threads.

For more information about the synchronization primitive instructions, see the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)).

## 2.5 Exception Model

The ARM Cortex-M4F processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration.

Table 2-8 on page 120 lists all exception types. Software can set eight priority levels on seven of these exceptions (system handlers) as well as on 106 interrupts (listed in Table 2-9 on page 121).

Priorities on the system handlers are set with the NVIC **System Handler Priority n (SYSPRIn)** registers. Interrupts are enabled through the NVIC **Interrupt Set Enable n (ENn)** register and prioritized with the NVIC **Interrupt Priority n (PRIn)** registers. Priorities can be grouped by splitting priority levels into preemption priorities and subpriorities. All the interrupt registers are described in “Nested Vectored Interrupt Controller (NVIC)” on page 142.

Internally, the highest user-programmable priority (0) is treated as fourth priority, after a Reset, Non-Maskable Interrupt (NMI), and a Hard Fault, in that order. Note that 0 is the default priority for all the programmable priorities.

---

**Important:** After a write to clear an interrupt source, it may take several processor cycles for the NVIC to see the interrupt source deassert. Thus if the interrupt clear is done as the last action in an interrupt handler, it is possible for the interrupt handler to complete while

the NVIC sees the interrupt as still asserted, causing the interrupt handler to be re-entered errantly. This situation can be avoided by either clearing the interrupt source at the beginning of the interrupt handler or by performing a read or write after the write to clear the interrupt source (and flush the write buffer).

See “Nested Vectored Interrupt Controller (NVIC)” on page 142 for more information on exceptions and interrupts.

### 2.5.1 Exception States

Each exception is in one of the following states:

- **Inactive.** The exception is not active and not pending.
- **Pending.** The exception is waiting to be serviced by the processor. An interrupt request from a peripheral or from software can change the state of the corresponding interrupt to pending.
- **Active.** An exception that is being serviced by the processor but has not completed.  
**Note:** An exception handler can interrupt the execution of another exception handler. In this case, both exceptions are in the active state.
- **Active and Pending.** The exception is being serviced by the processor, and there is a pending exception from the same source.

### 2.5.2 Exception Types

The exception types are:

- **Reset.** Reset is invoked on power up or a warm reset. The exception model treats reset as a special form of exception. When reset is asserted, the operation of the processor stops, potentially at any point in an instruction. When reset is deasserted, execution restarts from the address provided by the reset entry in the vector table. Execution restarts as privileged execution in Thread mode.
- **NMI.** A non-maskable Interrupt (NMI) can be signaled using the NMI signal or triggered by software using the **Interrupt Control and State (INTCTRL)** register. This exception has the highest priority other than reset. NMI is permanently enabled and has a fixed priority of -2. NMIs cannot be masked or prevented from activation by any other exception or preempted by any exception other than reset.
- **Hard Fault.** A hard fault is an exception that occurs because of an error during exception processing, or because an exception cannot be managed by any other exception mechanism. Hard faults have a fixed priority of -1, meaning they have higher priority than any exception with configurable priority.
- **Memory Management Fault.** A memory management fault is an exception that occurs because of a memory protection related fault, including access violation and no match. The MPU or the fixed memory protection constraints determine this fault, for both instruction and data memory transactions. This fault is used to abort instruction accesses to Execute Never (XN) memory regions, even if the MPU is disabled.
- **Bus Fault.** A bus fault is an exception that occurs because of a memory-related fault for an instruction or data memory transaction such as a prefetch fault or a memory access fault. This fault can be enabled or disabled.

- **Usage Fault.** A usage fault is an exception that occurs because of a fault related to instruction execution, such as:
  - An undefined instruction
  - An illegal unaligned access
  - Invalid state on instruction execution
  - An error on exception return
 An unaligned address on a word or halfword memory access or division by zero can cause a usage fault when the core is properly configured.
- **SVCcall.** A supervisor call (SVC) is an exception that is triggered by the SVC instruction. In an OS environment, applications can use SVC instructions to access OS kernel functions and device drivers.
- **Debug Monitor.** This exception is caused by the debug monitor (when not halting). This exception is only active when enabled. This exception does not activate if it is a lower priority than the current activation.
- **PendSV.** PendSV is a pendable, interrupt-driven request for system-level service. In an OS environment, use PendSV for context switching when no other exception is active. PendSV is triggered using the **Interrupt Control and State (INTCTRL)** register.
- **SysTick.** A SysTick exception is an exception that the system timer generates when it reaches zero when it is enabled to generate an interrupt. Software can also generate a SysTick exception using the **Interrupt Control and State (INTCTRL)** register. In an OS environment, the processor can use this exception as system tick.
- **Interrupt (IRQ).** An interrupt, or IRQ, is an exception signaled by a peripheral or generated by a software request and fed through the NVIC (prioritized). All interrupts are asynchronous to instruction execution. In the system, peripherals use interrupts to communicate with the processor. Table 2-9 on page 121 lists the interrupts on the TM4C129DNCPDT controller.

For an asynchronous exception, other than reset, the processor can execute another instruction between when the exception is triggered and when the processor enters the exception handler.

Privileged software can disable the exceptions that Table 2-8 on page 120 shows as having configurable priority (see the **SYSHNDCTRL** register on page 186 and the **DIS0** register on page 161).

For more information about hard faults, memory management faults, bus faults, and usage faults, see “Fault Handling” on page 129.

**Table 2-8. Exception Types**

| Exception Type               | Vector Number | Priority <sup>a</sup>     | Vector Address or Offset <sup>b</sup> | Activation                                                             |
|------------------------------|---------------|---------------------------|---------------------------------------|------------------------------------------------------------------------|
| -                            | 0             | -                         | 0x0000.0000                           | Stack top is loaded from the first entry of the vector table on reset. |
| Reset                        | 1             | -3 (highest)              | 0x0000.0004                           | Asynchronous                                                           |
| Non-Maskable Interrupt (NMI) | 2             | -2                        | 0x0000.0008                           | Asynchronous                                                           |
| Hard Fault                   | 3             | -1                        | 0x0000.000C                           | -                                                                      |
| Memory Management            | 4             | programmable <sup>c</sup> | 0x0000.0010                           | Synchronous                                                            |

**Table 2-8. Exception Types (continued)**

| Exception Type | Vector Number | Priority <sup>a</sup>     | Vector Address or Offset <sup>b</sup> | Activation                                               |
|----------------|---------------|---------------------------|---------------------------------------|----------------------------------------------------------|
| Bus Fault      | 5             | programmable <sup>c</sup> | 0x0000.0014                           | Synchronous when precise and asynchronous when imprecise |
| Usage Fault    | 6             | programmable <sup>c</sup> | 0x0000.0018                           | Synchronous                                              |
| -              | 7-10          | -                         | -                                     | Reserved                                                 |
| SVCall         | 11            | programmable <sup>c</sup> | 0x0000.002C                           | Synchronous                                              |
| Debug Monitor  | 12            | programmable <sup>c</sup> | 0x0000.0030                           | Synchronous                                              |
| -              | 13            | -                         | -                                     | Reserved                                                 |
| PendSV         | 14            | programmable <sup>c</sup> | 0x0000.0038                           | Asynchronous                                             |
| SysTick        | 15            | programmable <sup>c</sup> | 0x0000.003C                           | Asynchronous                                             |
| Interrupts     | 16 and above  | programmable <sup>d</sup> | 0x0000.0040 and above                 | Asynchronous                                             |

a. 0 is the default priority for all the programmable priorities.

b. See "Vector Table" on page 124.

c. See **SYSPR11** on page 183.

d. See **PRIn** registers on page 165.

**Table 2-9. Interrupts**

| Vector Number | Interrupt Number (Bit in Interrupt Registers) | Vector Address or Offset  | Description             |
|---------------|-----------------------------------------------|---------------------------|-------------------------|
| 0-15          | -                                             | 0x0000.0000 - 0x0000.003C | Processor exceptions    |
| 16            | 0                                             | 0x0000.0040               | GPIO Port A             |
| 17            | 1                                             | 0x0000.0044               | GPIO Port B             |
| 18            | 2                                             | 0x0000.0048               | GPIO Port C             |
| 19            | 3                                             | 0x0000.004C               | GPIO Port D             |
| 20            | 4                                             | 0x0000.0050               | GPIO Port E             |
| 21            | 5                                             | 0x0000.0054               | UART0                   |
| 22            | 6                                             | 0x0000.0058               | UART1                   |
| 23            | 7                                             | 0x0000.005C               | SSI0                    |
| 24            | 8                                             | 0x0000.0060               | I <sup>2</sup> C0       |
| 25            | 9                                             | 0x0000.0064               | PWM Fault               |
| 26            | 10                                            | 0x0000.0068               | PWM Generator 0         |
| 27            | 11                                            | 0x0000.006C               | PWM Generator 1         |
| 28            | 12                                            | 0x0000.0070               | PWM Generator 2         |
| 29            | 13                                            | 0x0000.0074               | QEI0                    |
| 30            | 14                                            | 0x0000.0078               | ADC0 Sequence 0         |
| 31            | 15                                            | 0x0000.007C               | ADC0 Sequence 1         |
| 32            | 16                                            | 0x0000.0080               | ADC0 Sequence 2         |
| 33            | 17                                            | 0x0000.0084               | ADC0 Sequence 3         |
| 34            | 18                                            | 0x0000.0088               | Watchdog Timers 0 and 1 |
| 35            | 19                                            | 0x0000.008C               | 16/32-Bit Timer 0A      |
| 36            | 20                                            | 0x0000.0090               | 16/32-Bit Timer 0B      |
| 37            | 21                                            | 0x0000.0094               | 16/32-Bit Timer 1A      |

Table 2-9. Interrupts (*continued*)

| Vector Number | Interrupt Number (Bit in Interrupt Registers) | Vector Address or Offset | Description          |
|---------------|-----------------------------------------------|--------------------------|----------------------|
| 38            | 22                                            | 0x0000.0098              | 16/32-Bit Timer 1B   |
| 39            | 23                                            | 0x0000.009C              | 16/32-Bit Timer 2A   |
| 40            | 24                                            | 0x0000.00A0              | 16/32-Bit Timer 2B   |
| 41            | 25                                            | 0x0000.00A4              | Analog Comparator 0  |
| 42            | 26                                            | 0x0000.00A8              | Analog Comparator 1  |
| 43            | 27                                            | 0x0000.00AC              | Analog Comparator 2  |
| 44            | 28                                            | 0x0000.00B0              | System Control       |
| 45            | 29                                            | 0x0000.00B4              | Flash Memory Control |
| 46            | 30                                            | 0x0000.00B8              | GPIO Port F          |
| 47            | 31                                            | 0x0000.00BC              | GPIO Port G          |

**Table 2-9. Interrupts (continued)**

| Vector Number | Interrupt Number (Bit in Interrupt Registers) | Vector Address or Offset | Description        |
|---------------|-----------------------------------------------|--------------------------|--------------------|
| 126           | 110                                           | 0x0000.01F8              | I <sup>2</sup> C 9 |
| 127-129       | 111-113                                       | -                        | Reserved           |

### 2.5.3 Exception Handlers

The processor handles exceptions using:

- **Interrupt Service Routines (ISRs).** Interrupts (IRQx) are the exceptions handled by ISRs.
- **Fault Handlers.** Hard fault, memory management fault, usage fault, and bus fault are fault exceptions handled by the fault handlers.
- **System Handlers.** NMI, PendSV, SVCall, SysTick, and the fault exceptions are all system exceptions that are handled by system handlers.

### 2.5.4 Vector Table

The vector table contains the reset value of the stack pointer and the start addresses, also called exception vectors, for all exception handlers. The vector table is constructed using the vector address or offset shown in Table 2-8 on page 120. Figure 2-6 on page 125 shows the order of the exception vectors in the vector table. The least-significant bit of each vector must be 1, indicating that the exception handler is Thumb code

**Figure 2-6. Vector Table**

| Exception number<br>(N+16) | IRQ number<br>(N) | Offset<br>0x040<br>+ 0x(N*4) | Vector                  |
|----------------------------|-------------------|------------------------------|-------------------------|
| .                          | .                 | .                            | IRQ N                   |
| .                          | .                 | .                            | .                       |
| .                          | .                 | 0x004C                       | .                       |
| 18                         | 2                 | 0x0048                       | IRQ2                    |

| 6                          | -10               | 0x0018                       | Usage fault             |
| 5                          | -11               | 0x0014                       | Bus fault               |
| 4                          | -12               | 0x0010                       | Memory management fault |
| 3                          | -13               | 0x000C                       | Hard fault              |
| 2                          | -14               | 0x0008                       | NMI                     |
| 1                          | .                 | 0x0004                       | Reset                   |
| 0                          | .                 | 0x0000                       | Initial SP value        |

On system reset, the vector table is fixed at address 0x0000.0000. Privileged software can write to the **Vector Table Offset (VTABLE)** register to relocate the vector table start address to a different memory location, in the range 0x0000.0400 to 0x3FFF.FC00 (see “Vector Table” on page 124). Note that when configuring the **VTABLE** register, the offset must be aligned on a 1024-byte boundary.

### 2.5.5 Exception Priorities

As Table 2-8 on page 120 shows, all exceptions have an associated priority, with a lower priority value indicating a higher priority and configurable priorities for all exceptions except Reset, Hard fault, and NMI. If software does not configure any priorities, then all exceptions with a configurable priority have a priority of 0. For information about configuring exception priorities, see page 183 and page 165.

**Note:** Configurable priority values for the Tiva™ C Series implementation are in the range 0-7. This means that the Reset, Hard fault, and NMI exceptions, with fixed negative priority values, always have higher priority than any other exception.

For example, assigning a higher priority value to IRQ[0] and a lower priority value to IRQ[1] means that IRQ[1] has higher priority than IRQ[0]. If both IRQ[1] and IRQ[0] are asserted, IRQ[1] is processed before IRQ[0].

If multiple pending exceptions have the same priority, the pending exception with the lowest exception number takes precedence. For example, if both IRQ[0] and IRQ[1] are pending and have the same priority, then IRQ[0] is processed before IRQ[1].

When the processor is executing an exception handler, the exception handler is preempted if a higher priority exception occurs. If an exception occurs with the same priority as the exception being handled, the handler is not preempted, irrespective of the exception number. However, the status of the new interrupt changes to pending.

### 2.5.6 Interrupt Priority Grouping

To increase priority control in systems with interrupts, the NVIC supports priority grouping. This grouping divides each interrupt priority register entry into two fields:

- An upper field that defines the group priority
- A lower field that defines a subpriority within the group

Only the group priority determines preemption of interrupt exceptions. When the processor is executing an interrupt exception handler, another interrupt with the same group priority as the interrupt being handled does not preempt the handler.

If multiple pending interrupts have the same group priority, the subpriority field determines the order in which they are processed. If multiple pending interrupts have the same group priority and subpriority, the interrupt with the lowest IRQ number is processed first.

For information about splitting the interrupt priority fields into group priority and subpriority, see page 177.

### 2.5.7 Exception Entry and Return

Descriptions of exception handling use the following terms:

- **Preemption.** When the processor is executing an exception handler, an exception can preempt the exception handler if its priority is higher than the priority of the exception being handled. See “Interrupt Priority Grouping” on page 126 for more information about preemption by an interrupt. When one exception preempts another, the exceptions are called nested exceptions. See “Exception Entry” on page 127 for more information.
- **Return.** Return occurs when the exception handler is completed, and there is no pending exception with sufficient priority to be serviced and the completed exception handler was not handling a late-arriving exception. The processor pops the stack and restores the processor state to the state it had before the interrupt occurred. See “Exception Return” on page 128 for more information.
- **Tail-Chaining.** This mechanism speeds up exception servicing. On completion of an exception handler, if there is a pending exception that meets the requirements for exception entry, the stack pop is skipped and control transfers to the new exception handler.
- **Late-Arriving.** This mechanism speeds up preemption. If a higher priority exception occurs during state saving for a previous exception, the processor switches to handle the higher priority exception and initiates the vector fetch for that exception. State saving is not affected by late arrival because the state saved is the same for both exceptions. Therefore, the state saving continues uninterrupted. The processor can accept a late arriving exception until the first instruction of the exception handler of the original exception enters the execute stage of the processor. On

return from the exception handler of the late-arriving exception, the normal tail-chaining rules apply.

#### 2.5.7.1 Exception Entry

Exception entry occurs when there is a pending exception with sufficient priority and either the processor is in Thread mode or the new exception is of higher priority than the exception being handled, in which case the new exception preempts the original exception.

When one exception preempts another, the exceptions are nested.

Sufficient priority means the exception has more priority than any limits set by the mask registers (see **PRIMASK** on page 101, **FAULTMASK** on page 102, and **BASEPRI** on page 103). An exception with less priority than this is pending but is not handled by the processor.

When the processor takes an exception, unless the exception is a tail-chained or a late-arriving exception, the processor pushes information onto the current stack. This operation is referred to as *stacking* and the structure of eight data words is referred to as *stack frame*.

When using floating-point routines, the Cortex-M4F processor automatically stacks the architected floating-point state on exception entry. Figure 2-7 on page 128 shows the Cortex-M4F stack frame layout when floating-point state is preserved on the stack as the result of an interrupt or an exception.

**Note:** Where stack space for floating-point state is not allocated, the stack frame is the same as that of ARMv7-M implementations without an FPU. Figure 2-7 on page 128 shows this stack frame also.

Figure 2-7. Exception Stack Frame

Immediately after stacking, the stack pointer indicates the lowest address in the stack frame.

The stack frame includes the return address, which is the address of the next instruction in the interrupted program. This value is restored to the **PC** at exception return so that the interrupted program resumes.

In parallel with the stacking operation, the processor performs a vector fetch that reads the exception handler start address from the vector table. When stacking is complete, the processor starts executing the exception handler. At the same time, the processor writes an **EXC\_RETURN** value to the **LR**, indicating which stack pointer corresponds to the stack frame and what operation mode the processor was in before the entry occurred.

If no higher-priority exception occurs during exception entry, the processor starts executing the exception handler and automatically changes the status of the corresponding pending interrupt to active.

If another higher-priority exception occurs during exception entry, known as late arrival, the processor starts executing the exception handler for this exception and does not change the pending status of the earlier exception.

### 2.5.7.2 Exception Return

Exception return occurs when the processor is in Handler mode and executes one of the following instructions to load the **EXC\_RETURN** value into the **PC**:

- An LDM or POP instruction that loads the **PC**
- A BX instruction using any register
- An LDR instruction with the **PC** as the destination

EXC\_RETURN is the value loaded into the **LR** on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. The lowest five bits of this value provide information on the return stack and processor mode. Table 2-10 on page 129 shows the EXC\_RETURN values with a description of the exception return behavior.

EXC\_RETURN bits 31:5 are all set. When this value is loaded into the **PC**, it indicates to the processor that the exception is complete, and the processor initiates the appropriate exception return sequence.

**Table 2-10. Exception Return Behavior**

| EXC_RETURN[31:0]          | Description                                                                                                                            |

## 2.6 Fault Handling

Faults are a subset of the exceptions (see “Exception Model” on page 118). The following conditions generate a fault:

- A bus error on an instruction fetch or vector table load or a data access.

- An internally detected error such as an undefined instruction or an attempt to change state with a BX instruction.
- Attempting to execute an instruction from a memory region marked as Non-Executable (XN).
- An MPU fault because of a privilege violation or an attempt to access an unmanaged region.

## 2.6.1 Fault Types

Table 2-11 on page 130 shows the types of fault, the handler used for the fault, the corresponding fault status register, and the register bit that indicates the fault has occurred. See page 190 for more information about the fault status registers.

**Table 2-11. Faults**

| Fault                                                                        | Handler                 | Fault Status Register                              | Bit Name          |
|------------------------------------------------------------------------------|-------------------------|----------------------------------------------------|-------------------|
| Bus error on a vector read                                                   | Hard fault              | <b>Hard Fault Status (HFAULTSTAT)</b>              | VECT              |
| Fault escalated to a hard fault                                              | Hard fault              | <b>Hard Fault Status (HFAULTSTAT)</b>              | FORCED            |
| MPU or default memory mismatch on instruction access                         | Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | IERR <sup>a</sup> |
| MPU or default memory mismatch on data access                                | Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | DERR              |
| MPU or default memory mismatch on exception stacking                         | Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | MSTKE             |
| MPU or default memory mismatch on exception unstacking                       | Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | MUSTKE            |
| MPU or default memory mismatch during lazy floating-point state preservation | Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | MLSPERR           |
| Bus error during exception stacking                                          | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | BSTKE             |
| Bus error during exception unstacking                                        | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | BUSTKE            |
| Bus error during instruction prefetch                                        | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | IBUS              |
| Bus error during lazy floating-point state preservation                      | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | BLSPE             |
| Precise data bus error                                                       | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | PRECISE           |
| Imprecise data bus error                                                     | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | IMPRE             |
| Attempt to access a coprocessor                                              | Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | NOCP              |

| Illegal unaligned load or store                                              | Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | UNALIGN           |
| Divide by 0                                                                  | Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | DIV0              |

a. Occurs on an access to an XN region even if the MPU is disabled.

b. Attempting to use an instruction set other than the Thumb instruction set, or returning to a non load-store-multiply instruction with ICI continuation.

## 2.6.2 Fault Escalation and Hard Faults

All fault exceptions except for hard fault have configurable exception priority (see **SYSPRI1** on page 183). Software can disable execution of the handlers for these faults (see **SYSHNDCTRL** on page 186).

Usually, the exception priority, together with the values of the exception mask registers, determines whether the processor enters the fault handler, and whether a fault handler can preempt another fault handler as described in “Exception Model” on page 118.

In some situations, a fault with configurable priority is treated as a hard fault. This process is called priority escalation, and the fault is described as *escalated to hard fault*. Escalation to hard fault occurs when:

- A fault handler causes the same kind of fault as the one it is servicing. This escalation to hard fault occurs because a fault handler cannot preempt itself because it must have the same priority as the current priority level.
- A fault handler causes a fault with the same or lower priority as the fault it is servicing. This situation happens because the handler for the new fault cannot preempt the currently executing fault handler.
- An exception handler causes a fault for which the priority is the same as or lower than the currently executing exception.
- A fault occurs and the handler for that fault is not enabled.

If a bus fault occurs during a stack push when entering a bus fault handler, the bus fault does not escalate to a hard fault. Thus if a corrupted stack causes a fault, the fault handler executes even though the stack push for the handler failed. The fault handler operates but the stack contents are corrupted.

**Note:** Only Reset and NMI can preempt the fixed priority hard fault. A hard fault can preempt any exception other than Reset, NMI, or another hard fault.

### 2.6.3 Fault Status Registers and Fault Address Registers

The fault status registers indicate the cause of a fault. For bus faults and memory management faults, the fault address register indicates the address accessed by the operation that caused the fault, as shown in Table 2-12 on page 131.

**Table 2-12. Fault Status and Fault Address Registers**

| Handler                 | Status Register Name                               | Address Register Name                           | Register Description |
|-------------------------|----------------------------------------------------|-------------------------------------------------|----------------------|
| Hard fault              | <b>Hard Fault Status (HFAULTSTAT)</b>              | -                                               | page 196             |
| Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | <b>Memory Management Fault Address (MMADDR)</b> | page 190<br>page 197 |
| Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | <b>Bus Fault Address (FAULTADDR)</b>            | page 190<br>page 198 |
| Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | -                                               | page 190             |

### 2.6.4 Lockup

The processor enters a lockup state if a hard fault occurs when executing the NMI or hard fault handlers. When the processor is in the lockup state, it does not execute any instructions. The processor remains in lockup state until it is reset, an NMI occurs, or it is halted by a debugger.

**Note:** If the lockup state occurs from the NMI handler, a subsequent NMI does not cause the processor to leave the lockup state.

## 2.7 Power Management

The Cortex-M4F processor sleep modes reduce power consumption:

- Sleep mode stops the processor clock.
- Deep-sleep mode stops the system clock and switches off the PLL and Flash memory.

The SLEEPDEEP bit of the **System Control (SYSCTRL)** register selects which sleep mode is used (see page 179). For more information about the behavior of the sleep modes, see “System Control” on page 245.

This section describes the mechanisms for entering sleep mode and the conditions for waking up from sleep mode, both of which apply to Sleep mode and Deep-sleep mode.

### 2.7.1 Entering Sleep Modes

This section describes the mechanisms software can use to put the processor into one of the sleep modes.

The system can generate spurious wake-up events, for example a debug operation wakes up the processor. Therefore, software must be able to put the processor back into sleep mode after such an event. A program might have an idle loop to put the processor back to sleep mode.

#### 2.7.1.1 Wait for Interrupt

The wait for interrupt instruction, WFI, causes immediate entry to sleep mode unless the wake-up condition is true (see “Wake Up from WFI or Sleep-on-Exit” on page 133). When the processor executes a WFI instruction, it stops executing instructions and enters sleep mode. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)) for more information.

#### 2.7.1.2 Wait for Event

The wait for event instruction, WFE, causes entry to sleep mode conditional on the value of a one-bit event register. When the processor executes a WFE instruction, it checks the event register. If the register is 0, the processor stops executing instructions and enters sleep mode. If the register is 1, the processor clears the register and continues executing instructions without entering sleep mode.

If the event register is 1, the processor must not enter sleep mode on execution of a WFE instruction. Typically, this situation occurs if an SEV instruction has been executed. Software cannot access this register directly.

See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)) for more information.

#### 2.7.1.3 Sleep-on-Exit

If the SLEEPEXIT bit of the **SYSCTRL** register is set, when the processor completes the execution of all exception handlers, it returns to Thread mode and immediately enters sleep mode. This mechanism can be used in applications that only require the processor to run when an exception occurs.

### 2.7.2 Wake Up from Sleep Mode

The conditions for the processor to wake up depend on the mechanism that caused it to enter sleep mode.

### 2.7.2.1 Wake Up from WFI or Sleep-on-Exit

Normally, the processor wakes up only when the NVIC detects an exception with sufficient priority to cause exception entry. Some embedded systems might have to execute system restore tasks after the processor wakes up and before executing an interrupt handler. Entry to the interrupt handler can be delayed by setting the PRIMASK bit and clearing the FAULTMASK bit. If an interrupt arrives that is enabled and has a higher priority than current exception priority, the processor wakes up but does not execute the interrupt handler until the processor clears PRIMASK. For more information about **PRIMASK** and **FAULTMASK**, see page 101 and page 102.

### 2.7.2.2 Wake Up from WFE

The processor wakes up if it detects an exception with sufficient priority to cause exception entry.

In addition, if the SEVONPEND bit in the **SYSCTRL** register is set, any new pending interrupt triggers an event and wakes up the processor, even if the interrupt is disabled or has insufficient priority to cause exception entry. For more information about **SYSCTRL**, see page 179.

## 2.8 Instruction Set Summary

The processor implements a version of the Thumb instruction set. Table 2-13 on page 133 lists the supported instructions.

**Note:** In Table 2-13 on page 133:

- Angle brackets, <>, enclose alternative forms of the operand
- Braces, {}, enclose optional operands
- The Operands column is not exhaustive
- Op2 is a flexible second operand that can be either a register or a constant
- Most instructions can use an optional condition code suffix

For more information on the instructions and operands, see the instruction descriptions in the *ARM® Cortex™-M4 Technical Reference Manual*.

**Table 2-13. Cortex-M4F Instruction Summary**

| Mnemonic  | Operands             | Brief Description              | Flags      |
|-----------|----------------------|--------------------------------|------------|
| ADC, ADCS | {Rd,} Rn, Op2        | Add with carry                 | N, Z, C, V |
| ADD, ADDS | {Rd,} Rn, Op2        | Add                            | N, Z, C, V |
| ADD, ADDW | {Rd,} Rn, #imm12     | Add                            | -          |
| ADR       | Rd, label            | Load PC-relative address       | -          |
| AND, ANDS | {Rd,} Rn, Op2        | Logical AND                    | N, Z, C    |
| ASR, ASRS | Rd, Rm, <Rs >#n      | Arithmetic shift right         | N, Z, C    |
| B         | label                | Branch                         | -          |
| BFC       | Rd, #lsb, #width     | Bit field clear                | -          |
| BFI       | Rd, Rn, #lsb, #width | Bit field insert               | -          |
| BIC, BICS | {Rd,} Rn, Op2        | Bit clear                      | N, Z, C    |
| BKPT      | #imm                 | Breakpoint                     | -          |
| BL        | label                | Branch with link               | -          |
| BLX       | Rm                   | Branch indirect with link      | -          |
| BX        | Rm                   | Branch indirect                | -          |
| CBNZ      | Rn, label            | Compare and branch if non-zero | -          |

Table 2-13. Cortex-M4F Instruction Summary (*continued*)

| Mnemonic      | Operands               | Brief Description                              | Flags      |
|---------------|------------------------|------------------------------------------------|------------|

## 3 Cortex-M4 Peripherals

This chapter provides information on the Tiva™ C Series implementation of the Cortex-M4 processor peripherals, including:

- SysTick (see page 141)

Provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism.

- Nested Vectored Interrupt Controller (NVIC) (see page 142)

- Facilitates low-latency exception and interrupt handling
- Controls power management
- Implements system control registers

- System Control Block (SCB) (see page 143)

Provides system implementation information and system control, including configuration, control, and reporting of system exceptions.

- Memory Protection Unit (MPU) (see page 143)

Supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

- Floating-Point Unit (FPU) (see page 148)

Fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

Table 3-1 on page 140 shows the address map of the Private Peripheral Bus (PPB). Some peripheral register regions are split into two address regions, as indicated by two addresses listed.

**Table 3-1. Core Peripheral Register Regions**

| Address                                            | Core Peripheral                      | Description (see page ...) |
|----------------------------------------------------|--------------------------------------|----------------------------|
| 0xE000.E010-0xE000.E01F                            | System Timer                         | 141                        |

| 0xE000.E008-0xE000.E00F<br>0xE000.ED00-0xE000.ED3F | System Control Block                 | 143                        |
| 0xE000.ED90-0xE000.EDB8                            | Memory Protection Unit               | 143                        |
| 0xE000.EF30-0xE000.EF44                            | Floating Point Unit                  | 148                        |

### 3.1 Functional Description

This chapter provides information on the Tiva™ C Series implementation of the Cortex-M4 processor peripherals: SysTick, NVIC, SCB, MPU, FPU.

### 3.1.1 System Timer (SysTick)

Cortex-M4 includes an integrated system timer, SysTick, which provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example as:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter used to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNT bit in the **STCTRL** control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

The timer consists of three registers:

- **SysTick Control and Status (STCTRL)**: A control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status.
- **SysTick Reload Value (STRELOAD)**: The reload value for the counter, used to provide the counter's wrap value.
- **SysTick Current Value (STCURRENT)**: The current value of the counter.

When enabled, the timer counts down on each clock from the reload value to zero, reloads (wraps) to the value in the **STRELOAD** register on the next clock edge, then decrements on subsequent clocks. Clearing the **STRELOAD** register disables the counter on the next wrap. When the counter reaches zero, the COUNT status bit is set. The COUNT bit clears on reads.

Writing to the **STCURRENT** register clears the register and the COUNT status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

The SysTick counter runs on the system clock. If this clock signal is stopped for low power mode, the SysTick counter stops. Ensure software uses aligned word accesses to access the SysTick registers.

The SysTick counter reload and current value are undefined at reset; the correct initialization sequence for the SysTick counter is:

1. Program the value in the **STRELOAD** register.
2. Clear the **STCURRENT** register by writing to it with any value.
3. Configure the **STCTRL** register for the required operation.

**Note:** When the processor is halted for debugging, the counter does not decrement.

### 3.1.2 Nested Vectored Interrupt Controller (NVIC)

This section describes the Nested Vectored Interrupt Controller (NVIC) and the registers it uses. The NVIC supports:

- 106 interrupts.
- A programmable priority level of 0-7 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.
- Low-latency exception and interrupt handling.
- Level and pulse detection of interrupt signals.
- Dynamic reprioritization of interrupts.
- Grouping of priority values into group priority and subpriority fields.
- Interrupt tail-chaining.
- An external Non-maskable interrupt (NMI).

The processor automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead, providing low latency exception handling.

#### 3.1.2.1 Level-Sensitive and Pulse Interrupts

The processor supports both level-sensitive and pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the processor clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the processor enters the ISR, it automatically removes the pending state from the interrupt (see “Hardware and Software Control of Interrupts” on page 142 for more information). For a level-sensitive interrupt, if the signal is not deasserted before the processor returns from the ISR, the interrupt becomes pending again, and the processor must execute its ISR again. As a result, the peripheral can hold the interrupt signal asserted until it no longer needs servicing.

#### 3.1.2.2 Hardware and Software Control of Interrupts

The Cortex-M4 latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- The NVIC detects that the interrupt signal is High and the interrupt is not active.
- The NVIC detects a rising edge on the interrupt signal.
- Software writes to the corresponding interrupt set-pending register bit, or to the **Software Trigger Interrupt (SWTRIG)** register to make a Software-Generated Interrupt pending. See the INT bit in the **PEND0** register on page 162 or **SWTRIG** on page 169.

A pending interrupt remains pending until one of the following:

- The processor enters the ISR for the interrupt, changing the state of the interrupt from pending to active. Then:
  - For a level-sensitive interrupt, when the processor returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the processor returns from the ISR the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR.

If the interrupt signal is not pulsed while the processor is in the ISR, when the processor returns from the ISR the state of the interrupt changes to inactive.
- Software writes to the corresponding interrupt clear-pending register bit
  - For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the state of the interrupt changes to inactive, if the state was pending or to active, if the state was active and pending.

### 3.1.3 System Control Block (SCB)

The System Control Block (SCB) provides system implementation information and system control, including configuration, control, and reporting of the system exceptions.

### 3.1.4 Memory Protection Unit (MPU)

This section describes the Memory protection unit (MPU). The MPU divides the memory map into a number of regions and defines the location, size, access permissions, and memory attributes of each region. The MPU supports independent attribute settings for each region, overlapping regions, and export of memory attributes to the system.

The memory attributes affect the behavior of memory accesses to the region. The Cortex-M4 MPU defines eight separate memory regions, 0-7, and a background region.

When memory regions overlap, a memory access is affected by the attributes of the region with the highest number. For example, the attributes for region 7 take precedence over the attributes of any region that overlaps region 7.

The background region has the same memory access attributes as the default memory map, but is accessible from privileged software only.

The Cortex-M4 MPU memory map is unified, meaning that instruction accesses and data accesses have the same region settings.

If a program accesses a memory location that is prohibited by the MPU, the processor generates a memory management fault, causing a fault exception and possibly causing termination of the process in an OS environment. In an OS environment, the kernel can update the MPU region setting dynamically based on the process to be executed. Typically, an embedded OS uses the MPU for memory protection.

Configuration of MPU regions is based on memory types (see “Memory Regions, Types and Attributes” on page 111 for more information).

Table 3-2 on page 144 shows the possible MPU region attributes. See the section called “MPU Configuration for a Tiva™ C Series Microcontroller” on page 148 for guidelines for programming a microcontroller implementation.

**Table 3-2. Memory Attributes Summary**

| Memory Type      | Description                                                     |
|------------------|-----------------------------------------------------------------|
| Strongly Ordered | All accesses to Strongly Ordered memory occur in program order. |
| Device           | Memory-mapped peripherals                                       |
| Normal           | Normal memory                                                   |

To avoid unexpected behavior, disable the interrupts before updating the attributes of a region that the interrupt handlers might access.

Ensure software uses aligned accesses of the correct size to access MPU registers:

- Except for the **MPU Region Attribute and Size (MPUATTR)** register, all MPU registers must be accessed with aligned word accesses.
- The **MPUATTR** register can be accessed with byte or aligned halfword or word accesses.

The processor does not support unaligned accesses to MPU registers.

When setting up the MPU, and if the MPU has previously been programmed, disable unused regions to prevent any previous region settings from affecting the new MPU setup.

### 3.1.4.1 Updating an MPU Region

To update the attributes for an MPU region, the **MPU Region Number (MPUNUMBER)**, **MPU Region Base Address (MPUBASE)** and **MPUATTR** registers must be updated. Each register can be programmed separately or with a multiple-word write to program all of these registers. You can use the **MPUBASEx** and **MPUATTRx** aliases to program up to four regions simultaneously using an STM instruction.

#### *Updating an MPU Region Using Separate Words*

This example simple code configures one region:

```
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER      ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]      ; Region Number
STR R4, [R0, #0x4]      ; Region Base Address
STRH R2, [R0, #0x8]     ; Region Size and Enable
STRH R3, [R0, #0xA]     ; Region Attribute
```

Disable a region before writing new region settings to the MPU if you have previously enabled the region being changed. For example:

```
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER      ; 0xE000ED98, MPU region number register
```

```

STR R1, [R0, #0x0]      ; Region Number
BIC R2, R2, #1          ; Disable
STRH R2, [R0, #0x8]     ; Region Size and Enable
STR R4, [R0, #0x4]      ; Region Base Address
STRH R3, [R0, #0xA]     ; Region Attribute
ORR R2, #1              ; Enable
STRH R2, [R0, #0x8]     ; Region Size and Enable

```

Software must use memory barrier instructions:

- Before MPU setup, if there might be outstanding memory transfers, such as buffered writes, that might be affected by the change in MPU settings.
- After MPU setup, if it includes memory transfers that must use the new MPU settings.

However, memory barrier instructions are not required if the MPU setup process starts by entering an exception handler, or is followed by an exception return, because the exception entry and exception return mechanism cause memory barrier behavior.

Software does not need any memory barrier instructions during MPU setup, because it accesses the MPU through the Private Peripheral Bus (PPB), which is a Strongly Ordered memory region.

For example, if all of the memory access behavior is intended to take effect immediately after the programming sequence, then a DSB instruction and an ISB instruction should be used. A DSB is required after changing MPU settings, such as at the end of context switch. An ISB is required if the code that programs the MPU region or regions is entered using a branch or call. If the programming sequence is entered using a return from exception, or by taking an exception, then an ISB is not required.

### Updating an MPU Region Using Multi-Word Writes

The MPU can be programmed directly using multi-word writes, depending how the information is divided. Consider the following reprogramming:

```

; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0] ; Region Number
STR R2, [R0, #0x4] ; Region Base Address
STR R3, [R0, #0x8] ; Region Attribute, Size and Enable

```

An STM instruction can be used to optimize this:

```

; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STM R0, {R1-R3}    ; Region number, address, attribute, size and enable

```

This operation can be done in two words for prepacked information, meaning that the **MPU Region Base Address (MPUBASE)** register (see page 203) contains the required region number and has the VALID bit set. This method can be used when the data is statically packed, for example in a boot loader:

```

; R1 = address and region number in one
; R2 = size and attributes in one
LDR R0, =MPUBASE      ; 0xE000ED9C, MPU Region Base register
STR R1, [R0, #0x0]    ; Region base address and region number combined
                        ; with VALID (bit 4) set
STR R2, [R0, #0x4]    ; Region Attribute, Size and Enable

```

### Subregions

Regions of 256 bytes or more are divided into eight equal-sized subregions. Set the corresponding bit in the SRD field of the **MPU Region Attribute and Size (MPUATTR)** register (see page 205) to disable a subregion. The least-significant bit of the SRD field controls the first subregion, and the most-significant bit controls the last subregion. Disabling a subregion means another region overlapping the disabled range matches instead. If no other enabled region overlaps the disabled subregion, the MPU issues a fault.

Regions of 32, 64, and 128 bytes do not support subregions. With regions of these sizes, the SRD field must be configured to 0x00, otherwise the MPU behavior is unpredictable.

### Example of SRD Use

Two regions with the same base address overlap. Region one is 128 KB, and region two is 512 KB. To ensure the attributes from region one apply to the first 128 KB region, configure the SRD field for region two to 0x03 to disable the first two subregions, as Figure 3-1 on page 146 shows.

**Figure 3-1. SRD Use Example**

#### 3.1.4.2 MPU Access Permission Attributes

The access permission bits, TEX, S, C, B, AP, and XN of the **MPUATTR** register, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

Table 3-3 on page 146 shows the encodings for the TEX, C, B, and S access permission bits. All encodings are shown for completeness, however the current implementation of the Cortex-M4 does not support the concept of cacheability or shareability. Refer to the section called “MPU Configuration for a Tiva™ C Series Microcontroller” on page 148 for information on programming the MPU for TM4C129DNC PDT implementations.

**Table 3-3. TEX, S, C, and B Bit Field Encoding**

| TEX  | S              | C | B | Memory Type      | Shareability | Other Attributes |
|------|----------------|---|---|------------------|--------------|------------------|
| 000b | x <sup>a</sup> | 0 | 0 | Strongly Ordered | Shareable    | -                |
| 000  | x <sup>a</sup> | 0 | 1 | Device           | Shareable    | -                |

Table 3-3. TEX, S, C, and B Bit Field Encoding (*continued*)

| TEX | S              | C | B              | Memory Type       | Shareability  | Other Attributes                                                                                            |
|-----|----------------|---|----------------|-------------------|---------------|-------------------------------------------------------------------------------------------------------------|
| 000 | 0              | 1 | 0              | Normal            | Not shareable | Outer and inner write-through. No write allocate.                                                           |
| 000 | 1              | 1 | 0              | Normal            | Shareable     |                                                                                                             |
| 000 | 0              | 1 | 1              | Normal            | Not shareable |                                                                                                             |
| 000 | 1              | 1 | 1              | Normal            | Shareable     |                                                                                                             |
| 001 | 0              | 0 | 0              | Normal            | Not shareable | Outer and inner non-cacheable.                                                                              |
| 001 | 1              | 0 | 0              | Normal            | Shareable     |                                                                                                             |
| 001 | x <sup>a</sup> | 0 | 1              | Reserved encoding | -             | -                                                                                                           |
| 001 | x <sup>a</sup> | 1 | 0              | Reserved encoding | -             | -                                                                                                           |
| 001 | 0              | 1 | 1              | Normal            | Not shareable | Outer and inner write-back. Write and read allocate.                                                        |
| 001 | 1              | 1 | 1              | Normal            | Shareable     |                                                                                                             |
| 010 | x <sup>a</sup> | 0 | 0              | Device            | Not shareable | Nonshared Device.                                                                                           |
| 010 | x <sup>a</sup> | 0 | 1              | Reserved encoding | -             | -                                                                                                           |
| 010 | x <sup>a</sup> | 1 | x <sup>a</sup> | Reserved encoding | -             | -                                                                                                           |
| 1BB | 0              | A | A              | Normal            | Not shareable | Cached memory (BB = outer policy, AA = inner policy). See Table 3-4 for the encoding of the AA and BB bits. |
| 1BB | 1              | A | A              | Normal            | Shareable     |                                                                                                             |

a. The MPU ignores the value of this bit.

Table 3-4 on page 147 shows the cache policy for memory attribute encodings with a TEX value in the range of 0x4-0x7.

Table 3-4. Cache Policy for Memory Attribute Encoding

| Encoding, AA or BB | Corresponding Cache Policy          |
|--------------------|-------------------------------------|
| 00                 | Non-cacheable                       |
| 01                 | Write back, write and read allocate |
| 10                 | Write through, no write allocate    |
| 11                 | Write back, no write allocate       |

Table 3-5 on page 147 shows the AP encodings in the **MPUATTR** register that define the access permissions for privileged and unprivileged software.

Table 3-5. AP Bit Field Encoding

| AP Bit Field | Privileged Permissions | Unprivileged Permissions | Description                                                  |
|--------------|------------------------|--------------------------|--------------------------------------------------------------|
| 000          | No access              | No access                | All accesses generate a permission fault.                    |
| 001          | RW                     | No access                | Access from privileged software only.                        |
| 010          | RW                     | RO                       | Writes by unprivileged software generate a permission fault. |
| 011          | RW                     | RW                       | Full access.                                                 |
| 100          | Unpredictable          | Unpredictable            | Reserved.                                                    |
| 101          | RO                     | No access                | Reads by privileged software only.                           |

**Table 3-5. AP Bit Field Encoding (continued)**

| AP Bit Field | Privileged Permissions | Unprivileged Permissions | Description                                        |
|--------------|------------------------|--------------------------|----------------------------------------------------|
| 110          | RO                     | RO                       | Read-only, by privileged or unprivileged software. |
| 111          | RO                     | RO                       | Read-only, by privileged or unprivileged software. |

**MPU Configuration for a Tiva™ C Series Microcontroller**

Tiva™ C Series microcontrollers have only a single processor and no caches. As a result, the MPU should be programmed as shown in Table 3-6 on page 148.

**Table 3-6. Memory Region Attributes for Tiva™ C Series Microcontrollers**

| Memory Region | TEX  | S | C | B | Memory Type and Attributes                           |
|---------------|------|---|---|---|------------------------------------------------------|
| Flash memory  | 000b | 0 | 1 | 0 | Normal memory, non-shareable, write-through          |
| Internal SRAM | 000b | 1 | 1 | 0 | Normal memory, shareable, write-through              |
| External SRAM | 000b | 1 | 1 | 1 | Normal memory, shareable, write-back, write-allocate |
| Peripherals   | 000b | 1 | 0 | 1 | Device memory, shareable                             |

In current Tiva™ C Series microcontroller implementations, the shareability and cache policy attributes do not affect the system behavior. However, using these settings for the MPU regions can make the application code more portable. The values given are for typical situations.

**3.1.4.3 MPU Mismatch**

When an access violates the MPU permissions, the processor generates a memory management fault (see “Exceptions and Interrupts” on page 108 for more information). The **MFAULTSTAT** register indicates the cause of the fault. See page 190 for more information.

**3.1.5 Floating-Point Unit (FPU)**

This section describes the Floating-Point Unit (FPU) and the registers it uses. The FPU provides:

- 32-bit instructions for single-precision (C float) data-processing operations
- Combined multiply and accumulate instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication with optional accumulate, division, and square-root
- Hardware support for denormals and all IEEE rounding modes
- 32 dedicated 32-bit single-precision registers, also addressable as 16 double-word registers
- Decoupled three stage pipeline

The Cortex-M4F FPU fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions. The FPU provides floating-point computation functionality that is compliant with the ANSI/IEEE Std 754-2008, IEEE Standard for Binary Floating-Point Arithmetic, referred to as the IEEE 754 standard. The FPU's single-precision extension registers can also be accessed as 16 doubleword registers for load, store, and move operations.

### 3.1.5.1 FPU Views of the Register Bank

The FPU provides an extension register file containing 32 single-precision registers. These can be viewed as:

- Sixteen 64-bit doubleword registers, D0-D15
- Thirty-two 32-bit single-word registers, S0-S31
- A combination of registers from the above views

**Figure 3-2. FPU Register Bank**

The mapping between the registers is as follows:

- $S_{\langle 2n \rangle}$  maps to the least significant half of  $D_{\langle n \rangle}$
- $S_{\langle 2n+1 \rangle}$  maps to the most significant half of  $D_{\langle n \rangle}$

For example, you can access the least significant half of the value in D6 by accessing S12, and the most significant half of the elements by accessing S13.

### 3.1.5.2 Modes of Operation

The FPU provides three modes of operation to accommodate a variety of applications.

**Full-Compliance mode.** In Full-Compliance mode, the FPU processes all operations according to the IEEE 754 standard in hardware.

**Flush-to-Zero mode.** Setting the FZ bit of the **Floating-Point Status and Control (FPSC)** register enables Flush-to-Zero mode. In this mode, the FPU treats all subnormal input operands of arithmetic CDP operations as zeros in the operation. Exceptions that result from a zero operand are signalled appropriately. VABS, VNEG, and VMOV are not considered arithmetic CDP operations and are not affected by Flush-to-Zero mode. A result that is tiny, as described in the IEEE 754 standard, where the destination precision is smaller in magnitude than the minimum normal value before rounding, is replaced with a zero. The IDC bit in **FPSC** indicates when an input flush occurs. The UFC bit in **FPSC** indicates when a result flush occurs.

**Default NaN mode.** Setting the DN bit in the **FPSC** register enables default NaN mode. In this mode, the result of any arithmetic data processing operation that involves an input NaN, or that generates a NaN result, returns the default NaN. Propagation of the fraction bits is maintained only by VABS,

VNEG, and VMOV operations. All other CDP operations ignore any information in the fraction bits of an input NaN.

### 3.1.5.3 Compliance with the IEEE 754 standard

When Default NaN (DN) and Flush-to-Zero (FZ) modes are disabled, FPv4 functionality is compliant with the IEEE 754 standard in hardware. No support code is required to achieve this compliance.

### 3.1.5.4 Complete Implementation of the IEEE 754 standard

The Cortex-M4F floating point instruction set does not support all operations defined in the IEEE 754-2008 standard. Unsupported operations include, but are not limited to the following:

- Remainder
- Round floating-point number to integer-valued floating-point number
- Binary-to-decimal conversions
- Decimal-to-binary conversions
- Direct comparison of single-precision and double-precision values

The Cortex-M4 FPU supports fused MAC operations as described in the IEEE standard. For complete implementation of the IEEE 754-2008 standard, floating-point functionality must be augmented with library functions.

### 3.1.5.5 IEEE 754 standard implementation choices

#### ***NaN handling***

All single-precision values with the maximum exponent field value and a nonzero fraction field are valid NaNs. A most-significant fraction bit of zero indicates a Signaling NaN (SNaN). A one indicates a Quiet NaN (QNaN). Two NaN values are treated as different NaNs if they differ in any bit. The below table shows the default NaN values.

| Sign | Fraction | Fraction                                |
|------|----------|-----------------------------------------|
| 0    | 0xFF     | bit [22] = 1, bits [21:0] are all zeros |

Processing of input NaNs for ARM floating-point functionality and libraries is defined as follows:

- In full-compliance mode, NaNs are handled as described in the ARM Architecture Reference Manual. The hardware processes the NaNs directly for arithmetic CDP instructions. For data transfer operations, NaNs are transferred without raising the Invalid Operation exception. For the non-arithmetic CDP instructions, VABS, VNEG, and VMOV, NaNs are copied, with a change of sign if specified in the instructions, without causing the Invalid Operation exception.
- In default NaN mode, arithmetic CDP instructions involving NaN operands return the default NaN regardless of the fractions of any NaN operands. SNaNs in an arithmetic CDP operation set the IOC flag, FPSCR[0]. NaN handling by data transfer and non-arithmetic CDP instructions is the same as in full-compliance mode.

**Table 3-7. QNaN and SNaN Handling**

| Instruction Type   | Default NaN Mode | With QNaN Operand                                                                                                                                   | With SNaN Operand                                                                                                                       |
|--------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Arithmetic CDP     | Off              | The QNaN or one of the QNaN operands, if there is more than one, is returned according to the rules given in the ARM Architecture Reference Manual. | IOC <sup>a</sup> set. The SNaN is quieted and the result NaN is determined by the rules given in the ARM Architecture Reference Manual. |
|                    | On               | Default NaN returns.                                                                                                                                | IOC <sup>a</sup> set. Default NaN returns.                                                                                              |

a. IOC is the Invalid Operation exception flag, FPSCR[0].

### Comparisons

Comparison results modify the flags in the FPSCR. You can use the MVRSPSR\_nzcv instruction (formerly FMSTAT) to transfer the current flags from the FPSCR to the APSR. See the ARM Architecture Reference Manual for mapping of IEEE 754-2008 standard predicates to ARM conditions. The flags used are chosen so that subsequent conditional execution of ARM instructions can test the predicates defined in the IEEE standard.

### Underflow

The Cortex-M4F FPU uses the before rounding form of tininess and the inexact result form of loss of accuracy as described in the IEEE 754-2008 standard to generate Underflow exceptions.

In flush-to-zero mode, results that are tiny before rounding, as described in the IEEE standard, are flushed to a zero, and the UFC flag, FPSCR[3], is set. See the ARM Architecture Reference Manual for information on flush-to-zero mode.

When the FPU is not in flush-to-zero mode, operations are performed on subnormal operands. If the operation does not produce a tiny result, it returns the computed result, and the UFC flag, FPSCR[3], is not set. The IXC flag, FPSCR[4], is set if the operation is inexact. If the operation produces a tiny result, the result is a subnormal or zero value, and the UFC flag, FPSCR[3], is set if the result was also inexact.

#### 3.1.5.6 Exceptions

The FPU sets the cumulative exception status flag in the FPSCR register as required for each instruction, in accordance with the FPUv4 architecture. The FPU does not support user-mode traps. The exception enable bits in the FPSCR read-as-zero, and writes are ignored. The processor also has six output pins, FPIX, FPUFC, FPOFC, FPDZC, FPIDC, and FPIOC, that each reflect the status of one of the cumulative exception flags. For a description of these outputs, see the *ARM Cortex-M4 Integration and Implementation Manual* (ARM DII 0239, available from ARM).

The processor can reduce the exception latency by using lazy stacking. See Auxiliary Control Register, ACTLR on page 4-5. This means that the processor reserves space on the stack for the FP state, but does not save that state information to the stack. See the ARMv7-M Architecture Reference Manual (available from ARM) for more information.

#### 3.1.5.7 Enabling the FPU

The FPU is disabled from reset. You must enable it before you can use any floating-point instructions. The processor must be in privileged mode to read from and write to the **Coprocessor Access**

**Control (CPAC) register.** The below example code sequence enables the FPU in both privileged and user modes.

```
; CPACR is located at address 0xE000ED88
LDR.W R0, =0xE000ED88
; Read CPACR
LDR R1, [R0]
; Set bits 20-23 to enable CP10 and CP11 coprocessors
ORR R1, R1, #(0xF << 20)
; Write back the modified value to the CPACR
STR R1, [R0]; wait for store to complete
DSB
;reset pipeline now the FPU is enabled
ISB
```

## 3.2 Register Map

Table 3-8 on page 152 lists the Cortex-M4 Peripheral SysTick, NVIC, MPU, FPU and SCB registers. The offset listed is a hexadecimal increment to the register's address, relative to the Core Peripherals base address of 0xE000.E000.

**Note:** Register spaces that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

**Table 3-8. Peripherals Register Map**

| Offset                                                       | Name      | Type | Reset       | Description                         | See page |

### 3.3 System Timer (SysTick) Register Descriptions

This section lists and describes the System Timer registers, in numerical order by address offset.

**Register 1: SysTick Control and Status Register (STCTRL), offset 0x010**

**Note:** This register can only be accessed from privileged mode.

The SysTick **STCTRL** register enables the SysTick features.

## SysTick Control and Status Register (STCTRL)

Base 0xE000.E000

Offset 0x010

Type RW, reset 0x0000.0000

|           |        |      |       | 0                | The counter is disabled.                                                                                                                                                                                                                                                        |
|           |        |      |       | 1                | Enables SysTick to operate in a multi-shot way. That is, the counter loads the RELOAD value and begins counting down. On reaching 0, the COUNT bit is set and an interrupt is generated if enabled by INTEN. The counter then loads the RELOAD value again and begins counting. |

**Register 2: SysTick Reload Value Register (STRELOAD), offset 0x014**

**Note:** This register can only be accessed from privileged mode.

The **STRELOAD** register specifies the start value to load into the **SysTick Current Value (STCURRENT)** register when the counter reaches 0. The start value can be between 0x1 and 0x00FF.FFFF. A start value of 0 is possible but has no effect because the SysTick interrupt and the COUNT bit are activated when counting from 1 to 0.

SysTick can be configured as a multi-shot timer, repeated over and over, firing every N+1 clock pulses, where N is any value from 1 to 0x00FF.FFFF. For example, if a tick interrupt is required every 100 clock pulses, 99 must be written into the RELOAD field.

Note that in order to access this register correctly, the system clock must be faster than 8 MHz.

Clearing this register also clears the COUNT bit of the <b>STCTRL</b> register. |

## 3.4 NVIC Register Descriptions

This section lists and describes the NVIC registers, in numerical order by address offset.

The NVIC registers can only be fully accessed from privileged mode, but interrupts can be pended while in unprivileged mode by enabling the **Configuration and Control (CFGCTRL)** register. Any other unprivileged mode access causes a bus fault.

Ensure software uses correctly aligned register accesses. The processor does not support unaligned accesses to NVIC registers.

An interrupt can enter the pending state even if it is disabled.

Before programming the **VTABLE** register to relocate the vector table, ensure the vector table entries of the new vector table are set up for fault handlers, NMI, and all enabled exceptions such as interrupts. For more information, see page 176.

**Register 4: Interrupt 0-31 Set Enable (EN0), offset 0x100****Register 5: Interrupt 32-63 Set Enable (EN1), offset 0x104****Register 6: Interrupt 64-95 Set Enable (EN2), offset 0x108****Register 7: Interrupt 96-113 Set Enable (EN3), offset 0x10C**

**Note:** This register can only be accessed from privileged mode.

The **ENn** registers enable interrupts and show which interrupts are enabled. Bit 0 of **EN0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **EN1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **EN2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **EN3** corresponds to Interrupt 96; bit 17 corresponds to Interrupt 113.

See Table 2-9 on page 121 for interrupt assignments.

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

| 31:0      | INT  | RW   | 0x0000.0000 | Interrupt Disable |

**Value Description**

0 On a read, indicates the interrupt is disabled.

On a write, no effect.

1 On a read, indicates the interrupt is enabled.

On a write, clears the corresponding INT[n] bit in the **EN0** register, disabling interrupt [n].

**Register 12: Interrupt 0-31 Set Pending (PEND0), offset 0x200****Register 13: Interrupt 32-63 Set Pending (PEND1), offset 0x204****Register 14: Interrupt 64-95 Set Pending (PEND2), offset 0x208****Register 15: Interrupt 96-113 Set Pending (PEND3), offset 0x20C**

**Note:** This register can only be accessed from privileged mode.

The **PEND<sub>n</sub>** registers force interrupts into the pending state and show which interrupts are pending. Bit 0 of **PEND0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **PEND1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **PEND2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **PEND3** corresponds to Interrupt 96; bit 17 corresponds to interrupt 113.

See Table 2-9 on page 121 for interrupt assignments.

| Bit/Field | Name | Type | Reset       | Description           |
|-----------|------|------|-------------|-----------------------|
| 31:0      | INT  | RW   | 0x0000.0000 | Interrupt Set Pending |

| Value | Description |
|-------|-------------|
|-------|-------------|

|   |                                                         |
|---|---------------------------------------------------------|
| 0 | On a read, indicates that the interrupt is not pending. |
|---|---------------------------------------------------------|

|  |                        |
|--|------------------------|
|  | On a write, no effect. |
|--|------------------------|

|   |                                                     |
|---|-----------------------------------------------------|
| 1 | On a read, indicates that the interrupt is pending. |
|---|-----------------------------------------------------|

|  |                                                                                   |
|--|-----------------------------------------------------------------------------------|
|  | On a write, the corresponding interrupt is set to pending even if it is disabled. |
|--|-----------------------------------------------------------------------------------|

If the corresponding interrupt is already pending, setting a bit has no effect.

A bit can only be cleared by setting the corresponding INT[n] bit in the **UNPEND0** register.

**Register 16: Interrupt 0-31 Clear Pending (UNPEND0), offset 0x280**

**Register 17: Interrupt 32-63 Clear Pending (UNPEND1), offset 0x284**

**Register 18: Interrupt 64-95 Clear Pending (UNPEND2), offset 0x288**

**Register 19: Interrupt 96-113 Clear Pending (UNPEND3), offset 0x28C**

**Note:** This register can only be accessed from privileged mode.

The **UNPEND<sub>n</sub>** registers show which interrupts are pending and remove the pending state from interrupts. Bit 0 of **UNPEND0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **UNPEND1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **UNPEND2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **UNPEND3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 113.

See Table 2-9 on page 121 for interrupt assignments.

#### Value Description

|   |                                                                                                                                                                                                                                                                    |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | On a read, indicates that the interrupt is not pending.<br>On a write, no effect.                                                                                                                                                                                  |
| 1 | On a read, indicates that the interrupt is pending.<br>On a write, clears the corresponding INT[n] bit in the <b>PEND0</b> register, so that interrupt [n] is no longer pending.<br>Setting a bit does not affect the active state of the corresponding interrupt. |

**Register 20: Interrupt 0-31 Active Bit (ACTIVE0), offset 0x300**

**Register 21: Interrupt 32-63 Active Bit (ACTIVE1), offset 0x304**

**Register 22: Interrupt 64-95 Active Bit (ACTIVE2), offset 0x308**

**Register 23: Interrupt 96-127 Active Bit (ACTIVE3), offset 0x30C**

**Note:** This register can only be accessed from privileged mode.

The **UNPENDn** registers indicate which interrupts are active. Bit 0 of **ACTIVE0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **ACTIVE1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **ACTIVE2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **ACTIVE3** corresponds to Interrupt 96; bit 17 corresponds to Interrupt 113.

See Table 2-9 on page 121 for interrupt assignments.

**Caution – Do not manually set or clear the bits in this register.**

#### Value Description

|   |                                                               |
|---|---------------------------------------------------------------|
| 0 | The corresponding interrupt is not active.                    |
| 1 | The corresponding interrupt is active, or active and pending. |

**Register 24: Interrupt 0-3 Priority (PRI0), offset 0x400**

**Register 25: Interrupt 4-7 Priority (PRI1), offset 0x404**

**Register 26: Interrupt 8-11 Priority (PRI2), offset 0x408**

**Register 27: Interrupt 12-15 Priority (PRI3), offset 0x40C**

**Register 28: Interrupt 16-19 Priority (PRI4), offset 0x410**

**Register 29: Interrupt 20-23 Priority (PRI5), offset 0x414**

**Register 30: Interrupt 24-27 Priority (PRI6), offset 0x418**

**Register 31: Interrupt 28-31 Priority (PRI7), offset 0x41C**

**Register 32: Interrupt 32-35 Priority (PRI8), offset 0x420**

**Register 33: Interrupt 36-39 Priority (PRI9), offset 0x424**

**Register 34: Interrupt 40-43 Priority (PRI10), offset 0x428**

**Register 35: Interrupt 44-47 Priority (PRI11), offset 0x42C**

**Register 36: Interrupt 48-51 Priority (PRI12), offset 0x430**

**Register 37: Interrupt 52-55 Priority (PRI13), offset 0x434**

**Register 38: Interrupt 56-59 Priority (PRI14), offset 0x438**

**Register 39: Interrupt 60-63 Priority (PRI15), offset 0x43C**

**Note:** This register can only be accessed from privileged mode.

The **PRIn** registers (see also page 167) provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

| PRIn Register Bit Field | Interrupt        |
|-------------------------|------------------|
| Bits 31:29              | Interrupt [4n+3] |
| Bits 23:21              | Interrupt [4n+2] |
| Bits 15:13              | Interrupt [4n+1] |
| Bits 7:5                | Interrupt [4n]   |

See Table 2-9 on page 121 for interrupt assignments.

Each priority level can be split into separate group priority and subpriority fields. The **PRIGROUP** field in the **Application Interrupt and Reset Control (APINT)** register (see page 177) indicates the position of the binary point that splits the priority and subpriority fields.

These registers can only be accessed from privileged mode.

## Interrupt 0-3 Priority (PRI0)

Base 0xE000.E000

Offset 0x400

Type RW, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                                                                                                                                             |

| 15:13     | INTB     | RW   | 0x0   | <p>Interrupt Priority for Interrupt [4n+1]</p> <p>This field holds a priority value, 0-7, for the interrupt with the number [4n+1], where n is the number of the <b>Interrupt Priority</b> register (n=0 for <b>PRI0</b>, and so on). The lower the value, the greater the priority of the corresponding interrupt.</p> |
| 12:8      | reserved | RO   | 0x0   | <p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>                                                                                                                    |
| 7:5       | INTA     | RW   | 0x0   | <p>Interrupt Priority for Interrupt [4n]</p> <p>This field holds a priority value, 0-7, for the interrupt with the number [4n], where n is the number of the <b>Interrupt Priority</b> register (n=0 for <b>PRI0</b>, and so on). The lower the value, the greater the priority of the corresponding interrupt.</p>     |
| 4:0       | reserved | RO   | 0x0   | <p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>                                                                                                                    |

**Register 40: Interrupt 64-67 Priority (PRI16), offset 0x440**

**Register 41: Interrupt 68-71 Priority (PRI17), offset 0x444**

**Register 42: Interrupt 72-75 Priority (PRI18), offset 0x448**

**Register 43: Interrupt 76-79 Priority (PRI19), offset 0x44C**

**Register 44: Interrupt 80-83 Priority (PRI20), offset 0x450**

**Register 45: Interrupt 84-87 Priority (PRI21), offset 0x454**

**Register 46: Interrupt 88-91 Priority (PRI22), offset 0x458**

**Register 47: Interrupt 92-95 Priority (PRI23), offset 0x45C**

**Register 48: Interrupt 96-99 Priority (PRI24), offset 0x460**

**Register 49: Interrupt 100-103 Priority (PRI25), offset 0x464**

**Register 50: Interrupt 104-107 Priority (PRI26), offset 0x468**

**Register 51: Interrupt 108-111 Priority (PRI27), offset 0x46C**

**Register 52: Interrupt 112-113 Priority (PRI28), offset 0x470**

**Note:** This register can only be accessed from privileged mode.

The **PRI<sub>n</sub>** registers (see also page 165) provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

| <b>PRI<sub>n</sub> Register Bit Field</b> | <b>Interrupt</b> |
|-------------------------------------------|------------------|
| Bits 31:29                                | Interrupt [4n+3] |
| Bits 23:21                                | Interrupt [4n+2] |
| Bits 15:13                                | Interrupt [4n+1] |
| Bits 7:5                                  | Interrupt [4n]   |

See Table 2-9 on page 121 for interrupt assignments.

Each priority level can be split into separate group priority and subpriority fields. The **PRIGROUP** field in the **Application Interrupt and Reset Control (APINT)** register (see page 177) indicates the position of the binary point that splits the priority and subpriority fields.

These registers can only be accessed from privileged mode.

**Note:** Because the last interrupt vector is number 113, bits [31:16] of the **PRI28** register are reserved.

## Interrupt 64-67 Priority (PRI16)

**Register 53: Software Trigger Interrupt (SWTRIG), offset 0xF00**

**Note:** Only privileged software can enable unprivileged access to the **SWTRIG** register.

Writing an interrupt number to the **SWTRIG** register generates a Software Generated Interrupt (SGI). See Table 2-9 on page 121 for interrupt assignments.

When the MAINPEND bit in the **Configuration and Control (CFGCTRL)** register (see page 181) is set, unprivileged software can access the **SWTRIG** register.

**3.5 System Control Block (SCB) Register Descriptions**

This section lists and describes the System Control Block (SCB) registers, in numerical order by address offset. The SCB registers can only be accessed from privileged mode.

All registers must be accessed with aligned word accesses except for the **FAULTSTAT** and **SYSPRI1-SYSPRI3** registers, which can be accessed with byte or aligned halfword or word accesses. The processor does not support unaligned accesses to system control block registers.

**Register 54: Auxiliary Control (ACTLR), offset 0x008**

**Note:** This register can only be accessed from privileged mode.

The **ACTLR** register provides disable bits for IT folding, write buffer use for accesses to the default memory map, and interruption of multi-cycle instructions. By default, this register is set to provide optimum performance from the Cortex-M4 processor and does not normally require modification.

In some situations, the processor can start executing the first instruction in an IT block while it is still executing the IT instruction. This behavior is called *IT folding*, and improves performance. However, IT folding can cause jitter in looping. If a task must avoid jitter, set the DISFOLD bit before executing the task, to disable IT folding.

**Register 56: Interrupt Control and State (INTCTRL), offset 0xD04**

**Note:** This register can only be accessed from privileged mode.

The **INCTRL** register provides a set-pending bit for the NMI exception, and set-pending and clear-pending bits for the PendSV and SysTick exceptions. In addition, bits in this register indicate the exception number of the exception being processed, whether there are preempted active exceptions, the exception number of the highest priority pending exception, and whether any interrupts are pending.

When writing to **INCTRL**, the effect is unpredictable when writing a 1 to both the PENDSV and UNPENDSV bits, or writing a 1 to both the PENDSTSET and PENDSTCLR bits.

**Interrupt Control and State (INTCTRL)**

Base 0xE000.E000

Offset 0xD04

Type RW, reset 0x0000.0000

|----|---------|----|---|-----------------|
| 31 | NMISSET | RW | 0 | NMI Set Pending |
|----|---------|----|---|-----------------|

**Value Description**

0 On a read, indicates an NMI exception is not pending.

On a write, no effect.

1 On a read, indicates an NMI exception is pending.

On a write, changes the NMI exception state to pending.

Because NMI is the highest-priority exception, normally the processor enters the NMI exception handler as soon as it registers the setting of this bit, and clears this bit on entering the interrupt handler. A read of this bit by the NMI exception handler returns 1 only if the NMI signal is reasserted while the processor is executing that handler.

|----|--------|----|---|--------------------|
| 28 | PENDSV | RW | 0 | PendSV Set Pending |
|----|--------|----|---|--------------------|

**Value Description**

0 On a read, indicates a PendSV exception is not pending.

On a write, no effect.

1 On a read, indicates a PendSV exception is pending.

On a write, changes the PendSV exception state to pending.

Setting this bit is the only way to set the PendSV exception state to pending. This bit is cleared by writing a 1 to the UNPENDSV bit.

The exception numbers can be found in the description for the VECPEND field. If this field is clear, the processor is in Thread mode. This field contains the same value as the ISRNUM field in the <b>IPSR</b> register.</p> <p>Subtract 16 from this value to obtain the IRQ number required to index into the <b>Interrupt Set Enable (ENn)</b>, <b>Interrupt Clear Enable (DISn)</b>, <b>Interrupt Set Pending (PENDn)</b>, <b>Interrupt Clear Pending (UNPENDn)</b>, and <b>Interrupt Priority (PRIn)</b> registers (see page 97).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |       |             |      |                                                   |      |                                                                                                    |      |     |      |            |      |                         |      |           |      |             |           |          |      |        |      |                    |      |          |      |        |      |         |      |                    |      |                    |     |     |      |                      |

Register 57: Vector Table Offset (VTABLE), offset 0xD08

**Note:** This register can only be accessed from privileged mode.

The **VTABLE** register indicates the offset of the vector table base address from memory address 0x0000.0000.

Vector Table Offset (VTABLE)

Base 0xE000.E000  
Offset 0xD08  
Type RW, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset    | Description                                                                                                                                                                                                                            |
|-----------|----------|------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:10     | OFFSET   | RW   | 0x000.00 | Vector Table Offset<br><br>When configuring the OFFSET field, the offset must be aligned to the number of exception entries in the vector table. Because there are 112 interrupts, the offset must be aligned on a 1024-byte boundary. |
| 9:0       | reserved | RO   | 0x00     | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                          |

**Register 58: Application Interrupt and Reset Control (APINT), offset 0xD0C**

**Note:** This register can only be accessed from privileged mode.

The **APINT** register provides priority grouping control for the exception model, endian status for data accesses, and reset control of the system. To write to this register, 0x05FA must be written to the VECTKEY field, otherwise the write is ignored.

The PRIGROUP field indicates the position of the binary point that splits the INTx fields in the **Interrupt Priority (PRIx)** registers into separate group priority and subpriority fields. Table 3-9 on page 177 shows how the PRIGROUP value controls this split. The bit numbers in the Group Priority Field and Subpriority Field columns in the table refer to the bits in the INTA field. For the INTB field, the corresponding bits are 15:13; for INTC, 23:21; and for INTD, 31:29.

**Note:** Determining preemption of an exception uses only the group priority field.

**Table 3-9. Interrupt Priority Levels**

| PRIGROUP Bit Field | Binary Point <sup>a</sup> | Group Priority Field | Subpriority Field | Group Priorities | Subpriorities |
|--------------------|---------------------------|----------------------|-------------------|------------------|---------------|
| 0x0 - 0x4          | bxxx.                     | [7:5]                | None              | 8                | 1             |
| 0x5                | bxx.y                     | [7:6]                | [5]               | 4                | 2             |
| 0x6                | bx.yy                     | [7]                  | [6:5]             | 2                | 4             |
| 0x7                | b.yyy                     | None                 | [7:5]             | 1                | 8             |

a. INTx field showing the binary point. An x denotes a group priority field bit, and a y denotes a subpriority field bit.

**Register 60: Configuration and Control (CFGCTRL), offset 0xD14**

**Note:** This register can only be accessed from privileged mode.

The **CFGCTRL** register controls entry to Thread mode and enables: the handlers for NMI, hard fault and faults escalated by the **FAULTMASK** register to ignore bus faults; trapping of divide by zero and unaligned accesses; and access to the **SWTRIG** register by unprivileged software (see page 169).

**Configuration and Control (CFGCTRL)**

Base 0xE000.E000

**Register 63: System Handler Priority 3 (SYSPRI3), offset 0xD20**

**Note:** This register can only be accessed from privileged mode.

The **SYSPRI3** register configures the priority level, 0 to 7 of the SysTick exception and PendSV handlers. This register is byte-accessible.

**Register 64: System Handler Control and State (SYSHNDCTRL), offset 0xD24**

**Note:** This register can only be accessed from privileged mode.

The **SYSHNDCTRL** register enables the system handlers, and indicates the pending status of the usage fault, bus fault, memory management fault, and SVC exceptions as well as the active status of the system handlers.

If a system handler is disabled and the corresponding fault occurs, the processor treats the fault as a hard fault.

This register can be modified to change the pending or active status of system exceptions. An OS kernel can write to the active bits to perform a context switch that changes the current exception type.

**Caution – Software that changes the value of an active bit in this register without correct adjustment to the stacked content can cause the processor to generate a fault exception. Ensure software that writes to this register retains and subsequently restores the current active status.**

**If the value of a bit in this register must be modified after enabling the system handlers, a read-modify-write procedure must be used to ensure that only the required bit is modified.**

**System Handler Control and State (SYSHNDCTRL)**

**Register 65: Configurable Fault Status (FAULTSTAT), offset 0xD28**

**Note:** This register can only be accessed from privileged mode.

The **FAULTSTAT** register indicates the cause of a memory management fault, bus fault, or usage fault. Each of these functions is assigned to a subregister as follows:

- **Usage Fault Status (UFAULTSTAT)**, bits 31:16
- **Bus Fault Status (BFAULTSTAT)**, bits 15:8
- **Memory Management Fault Status (MFAULTSTAT)**, bits 7:0

**FAULTSTAT** is byte accessible. **FAULTSTAT** or its subregisters can be accessed as follows:

- The complete **FAULTSTAT** register, with a word access to offset 0xD28
- The **MFAULTSTAT**, with a byte access to offset 0xD28
- The **MFAULTSTAT** and **BFAULTSTAT**, with a halfword access to offset 0xD28
- The **BFAULTSTAT**, with a byte access to offset 0xD29
- The **UFAULTSTAT**, with a halfword access to offset 0xD2A

Bits are cleared by writing a 1 to them.

In a fault handler, the true faulting address can be determined by:

1. Read and save the **Memory Management Fault Address (MMADDR)** or **Bus Fault Address (FAULTADDR)** value.
2. Read the MMARV bit in **MFAULTSTAT**, or the BFARV bit in **BFAULTSTAT** to determine if the **MMADDR** or **FAULTADDR** contents are valid.

Software must follow this sequence because another higher priority exception might change the **MMADDR** or **FAULTADDR** value. For example, if a higher priority handler preempts the current fault handler, the other fault might change the **MMADDR** or **FAULTADDR** value.

**Configurable Fault Status (FAULTSTAT)**

Base 0xE000.E000  
Offset 0xD28  
Type RW1C, reset 0x0000.0000

**Register 67: Memory Management Fault Address (MMADDR), offset 0xD34**

**Note:** This register can only be accessed from privileged mode.

The **MMADDR** register contains the address of the location that generated a memory management fault. When an unaligned access faults, the address in the **MMADDR** register is the actual address that faulted. Because a single read or write instruction can be split into multiple aligned accesses, the fault address can be any address in the range of the requested access size. Bits in the **Memory Management Fault Status (MFAULTSTAT)** register indicate the cause of the fault and whether the value in the **MMADDR** register is valid (see page 190).

Register 68: Bus Fault Address (FAULTADDR), offset 0xD38

**Note:** This register can only be accessed from privileged mode.

The **FAULTADDR** register contains the address of the location that generated a bus fault. When an unaligned access faults, the address in the **FAULTADDR** register is the one requested by the instruction, even if it is not the address of the fault. Bits in the **Bus Fault Status (BFAULTSTAT)** register indicate the cause of the fault and whether the value in the **FAULTADDR** register is valid (see page 190).

3.6 Memory Protection Unit (MPU) Register Descriptions

This section lists and describes the Memory Protection Unit (MPU) registers, in numerical order by address offset.

The MPU registers can only be accessed from privileged mode.

**Register 69: MPU Type (MPUTYPE), offset 0xD90****Note:** This register can only be accessed from privileged mode.

The **MPUTYPE** register indicates whether the MPU is present, and if so, how many regions it supports.

**MPU Type (MPUTYPE)**

**Register 70: MPU Control (MPUCTRL), offset 0xD94**

**Note:** This register can only be accessed from privileged mode.

The **MPUCTRL** register enables the MPU, enables the default memory map background region, and enables use of the MPU when in the hard fault, Non-maskable Interrupt (NMI), and **Fault Mask Register (FAULTMASK)** escalated handlers.

When the ENABLE and PRIVDEFEN bits are both set:

- For privileged accesses, the default memory map is as described in “Memory Model” on page 108. Any access by privileged software that does not address an enabled memory region behaves as defined by the default memory map.
- Any access by unprivileged software that does not address an enabled memory region causes a memory management fault.

Execute Never (XN) and Strongly Ordered rules always apply to the System Control Space regardless of the value of the ENABLE bit.

When the ENABLE bit is set, at least one region of the memory map must be enabled for the system to function unless the PRIVDEFEN bit is set. If the PRIVDEFEN bit is set and no regions are enabled, then only privileged software can operate.

When the ENABLE bit is clear, the system uses the default memory map, which has the same memory attributes as if the MPU is not implemented (see Table 2-5 on page 112 for more information). The default memory map applies to accesses from both privileged and unprivileged software.

When the MPU is enabled, accesses to the System Control Space and vector table are always permitted. Other areas are accessible based on regions and whether PRIVDEFEN is set.

Unless HFNMIENA is set, the MPU is not enabled when the processor is executing the handler for an exception with priority –1 or –2. These priorities are only possible when handling a hard fault or NMI exception or when **FAULTMASK** is enabled. Setting the HFNMIENA bit enables the MPU when operating with these two priorities.

Register 71: MPU Region Number (MPUNUMBER), offset 0xD98

**Note:** This register can only be accessed from privileged mode.

The **MPUNUMBER** register selects which memory region is referenced by the **MPU Region Base Address (MPUBASE)** and **MPU Region Attribute and Size (MPUATTR)** registers. Normally, the required region number should be written to this register before accessing the **MPUBASE** or the **MPUATTR** register. However, the region number can be changed by writing to the **MPUBASE** register with the VALID bit set (see page 203). This write updates the value of the REGION field.

MPU Region Number (MPUNUMBER)

Base 0xE000.E000  
Offset 0xD98  
Type RW, reset 0x0000.0000

| 2:0       | NUMBER   | RW   | 0x0        | MPU Region to Access<br>This field indicates the MPU region referenced by the <b>MPUBASE</b> and <b>MPUATTR</b> registers. The MPU supports eight memory regions.                             |

**Register 72: MPU Region Base Address (MPUBASE), offset 0xD9C****Register 73: MPU Region Base Address Alias 1 (MPUBASE1), offset 0xDA4****Register 74: MPU Region Base Address Alias 2 (MPUBASE2), offset 0xDAC****Register 75: MPU Region Base Address Alias 3 (MPUBASE3), offset 0xDB4**

**Note:** This register can only be accessed from privileged mode.

The **MPUBASE** register defines the base address of the MPU region selected by the **MPU Region Number (MPUNUMBER)** register and can update the value of the **MPUNUMBER** register. To change the current region number and update the **MPUNUMBER** register, write the **MPUBASE** register with the **VALID** bit set.

The **ADDR** field is bits 31:*N* of the **MPUBASE** register. Bits (*N*-1):5 are reserved. The region size, as specified by the **SIZE** field in the **MPU Region Attribute and Size (MPUATTR)** register, defines the value of *N* where:

$$N = \text{Log}_2(\text{Region size in bytes})$$

If the region size is configured to 4 GB in the **MPUATTR** register, there is no valid **ADDR** field. In this case, the region occupies the complete memory map, and the base address is 0x0000.0000.

The base address is aligned to the size of the region. For example, a 64-KB region must be aligned on a multiple of 64 KB, for example, at 0x0001.0000 or 0x0002.0000.

**Register 76: MPU Region Attribute and Size (MPUATTR), offset 0xDA0****Register 77: MPU Region Attribute and Size Alias 1 (MPUATTR1), offset 0xDA8****Register 78: MPU Region Attribute and Size Alias 2 (MPUATTR2), offset 0xDB0****Register 79: MPU Region Attribute and Size Alias 3 (MPUATTR3), offset 0xDB8**

**Note:** This register can only be accessed from privileged mode.

The **MPUATTR** register defines the region size and memory attributes of the MPU region specified by the **MPU Region Number (MPUNUMBER)** register and enables that region and any subregions.

The **MPUATTR** register is accessible using word or halfword accesses with the most-significant halfword holding the region attributes and the least-significant halfword holds the region size and the region and subregion enable bits.

The MPU access permission attribute bits, XN, AP, TEX, S, C, and B, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

The **SIZE** field defines the size of the MPU memory region specified by the **MPUNUMBER** register as follows:

$$(\text{Region size in bytes}) = 2^{(\text{SIZE}+1)}$$

The smallest permitted region size is 32 bytes, corresponding to a **SIZE** value of 4. Table 3-10 on page 205 gives example **SIZE** values with the corresponding region size and value of **N** in the **MPU Region Base Address (MPUBASE)** register.

**Table 3-10. Example SIZE Field Values**

| SIZE Encoding | Region Size | Value of N <sup>a</sup>                                                              | Note                   |
|---------------|-------------|--------------------------------------------------------------------------------------|------------------------|
| 00100b (0x4)  | 32 B        | 5                                                                                    | Minimum permitted size |
| 01001b (0x9)  | 1 KB        | 10                                                                                   | -                      |
| 10011b (0x13) | 1 MB        | 20                                                                                   | -                      |
| 11101b (0x1D) | 1 GB        | 30                                                                                   | -                      |
| 11111b (0x1F) | 4 GB        | No valid ADDR field in <b>MPUBASE</b> ; the region occupies the complete memory map. | Maximum possible size  |

a. Refers to the **N** parameter in the **MPUBASE** register (see page 203).

### 3.7 Floating-Point Unit (FPU) Register Descriptions

This section lists and describes the Floating-Point Unit (FPU) registers, in numerical order by address offset.

**Register 80: Coprocessor Access Control (CPAC), offset 0xD88**

The **CPAC** register specifies the access privileges for coprocessors.

**Coprocessor Access Control (CPAC)**

Base 0xE000.E000

Offset 0xD88

Type RW, reset 0x0000.0000

**Register 81: Floating-Point Context Control (FPCC), offset 0xF34**

The **FPCC** register sets or returns FPU control data.

**Floating-Point Context Control (FPCC)**

Base 0xE000.E000

Offset 0xF34

Type RW, reset 0xC000.0000

## 4 JTAG Interface

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is comprised of four pins: TCK, TMS, TDI, and TD0. Data is transmitted serially into the controller on TDI and out of the controller on TD0. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The TM4C129DNCPDT JTAG controller works with the ARM JTAG controller built into the Cortex-M4F core by multiplexing the TD0 outputs from both JTAG controllers. ARM JTAG instructions select the ARM TD0 output while JTAG instructions select the TD0 output. The multiplexer is controlled by the JTAG controller, which has comprehensive programming for the ARM, Tiva™ C Series microcontroller, and unimplemented JTAG instructions.

The TM4C129DNCPDT JTAG module has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, and EXTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
  - Serial Wire JTAG Debug Port (SWJ-DP)
  - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
  - Data Watchpoint and Trace (DWT) unit for implementing watchpoints, trigger resources, and system profiling
  - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
  - Embedded Trace Macrocell (ETM) for instruction trace capture
  - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

See the *ARM® Debug Interface V5 Architecture Specification* for more information on the ARM JTAG controller.

## 4.1 Block Diagram

Figure 4-1. JTAG Module Block Diagram

## 4.2 Signal Description

The following table lists the external signals of the JTAG/SWD controller and describes the function of each. The JTAG/SWD controller signals are alternate functions for some GPIO signals, however note that the reset state of the pins is for the JTAG/SWD function. The JTAG/SWD controller signals are under commit protection and require a special process to be configured as GPIOs, see “Commit Control” on page 753. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the JTAG/SWD controller signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) is set to choose the JTAG/SWD function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPTCL)** register (page 788) to assign the JTAG/SWD controller signals to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 742.

Table 4-1. JTAG\_SWD\_SWO Signals (128TQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description         |
|----------|------------|--------------------------|----------|-------------|---------------------|
| SWCLK    | 100        | PC0 (1)                  | I        | TTL         | JTAG/SWD CLK.       |

| TCK      | 100        | PC0 (1)                  | I        | TTL         | JTAG/SWD CLK.       |
| TDI      | 98         | PC2 (1)                  | I        | TTL         | JTAG TDI.           |
| TDO      | 97         | PC3 (1)                  | O        | TTL         | JTAG TDO and SWO.   |
| TMS      | 99         | PC1 (1)                  | I        | TTL         | JTAG TMS and SWDIO. |

## 4.3 Functional Description

A high-level conceptual drawing of the JTAG module is shown in Figure 4-1 on page 214. The JTAG module is composed of the Test Access Port (TAP) controller and serial shift chains with parallel update registers. The TAP controller is a simple state machine controlled by the TCK and TMS inputs. The current state of the TAP controller depends on the sequence of values captured on TMS at the rising edge of TCK. The TAP controller determines when the serial shift chains capture new data, shift data from TDI towards TD0, and update the parallel load registers. The current state of the TAP controller also determines whether the Instruction Register (IR) chain or one of the Data Register (DR) chains is being accessed.

The serial shift chains with parallel load registers are comprised of a single Instruction Register (IR) chain and multiple Data Register (DR) chains. The current instruction loaded in the parallel load register determines which DR chain is captured, shifted, or updated during the sequencing of the TAP controller.

Some instructions, like EXTEST, operate on data currently in a DR chain and do not capture, shift, or update any of the chains. Instructions that are not implemented decode to the BYPASS instruction to ensure that the serial path between TDI and TD0 is always connected (see Table 4-3 on page 222 for a list of implemented instructions).

See “JTAG and Boundary Scan” on page 1880 for JTAG timing diagrams.

Depending on the reset source, the effect on the JTAG module varies. The following reset sources reset the entire JTAG Module:

- Externally generated Power-On Reset

The following reset sources reset only the JTAG pin configuration:

- RST pin Power-On Reset
- Brown-Out Power-On Reset
- Watchdog Power-On Reset
- HIB Module Power-On Reset
- RST pin System Reset
- Brown-Out System Reset
- Software System Reset Request (using the SYSRESREQ bit in the **APINT** register)
- Software Peripheral Reset
- Watchdog System Reset
- HIB Module System Reset

### 4.3.1 JTAG Interface Pins

The JTAG interface consists of four standard pins: TCK, TMS, TDI, and TD0. These pins and their associated state after a power-on reset or reset caused by the RST input are given in Table 4-2. Detailed information on each pin follows.

**Note:** The following pins are configured as JTAG port pins out of reset. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 742 for information on how to reprogram the configuration of these pins.

**Table 4-2. JTAG Port Pins State after Power-On Reset or  $\overline{\text{RST}}$  assertion**

| Pin Name | Data Direction | Internal Pull-Up | Internal Pull-Down | Drive Strength | Drive Value |
|----------|----------------|------------------|--------------------|----------------|-------------|
| TCK      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TMS      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TDI      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TDO      | Output         | Enabled          | Disabled           | 2-mA driver    | High-Z      |

#### 4.3.1.1 Test Clock Input (TCK)

The TCK pin is the clock for the JTAG module. This clock is provided so the test logic can operate independently of any other system clocks and to ensure that multiple JTAG TAP controllers that are daisy-chained together can synchronously communicate serial test data between components. During normal operation, TCK is driven by a free-running clock with a nominal 50% duty cycle. When necessary, TCK can be stopped at 0 or 1 for extended periods of time. While TCK is stopped at 0 or 1, the state of the TAP controller does not change and data in the JTAG Instruction and Data Registers is not lost.

By default, the internal pull-up resistor on the TCK pin is enabled after reset, assuring that no clocking occurs if the pin is not driven from an external source. The internal pull-up and pull-down resistors can be turned off to save internal power as long as the TCK pin is constantly being driven by an external source (see page 777 and page 779).

#### 4.3.1.2 Test Mode Select (TMS)

The TMS pin selects the next state of the JTAG TAP controller. TMS is sampled on the rising edge of TCK. Depending on the current TAP state and the sampled value of TMS, the next state may be entered. Because the TMS pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TMS to change on the falling edge of TCK.

Holding TMS high for five consecutive TCK cycles drives the TAP controller state machine to the Test-Logic-Reset state. When the TAP controller enters the Test-Logic-Reset state, the JTAG module and associated registers are reset to their default values. This procedure should be performed to initialize the JTAG controller. The JTAG Test Access Port state machine can be seen in its entirety in Figure 4-2 on page 218.

By default, the internal pull-up resistor on the TMS pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC1/TMS; otherwise JTAG communication could be lost (see page 777).

#### 4.3.1.3 Test Data Input (TDI)

The TDI pin provides a stream of serial information to the IR chain and the DR chains. TDI is sampled on the rising edge of TCK and, depending on the current TAP state and the current instruction, may present this data to the proper shift register chain. Because the TDI pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TDI to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDI pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC2/TDI; otherwise JTAG communication could be lost (see page 777).

#### 4.3.1.4 Test Data Output (TDO)

The TDO pin provides an output stream of serial information from the IR chain or the DR chains. The value of TDO depends on the current TAP state, the current instruction, and the data in the chain being accessed. In order to save power when the JTAG port is not being used, the TDO pin is placed in an inactive drive state when not actively shifting out data. Because TDO can be connected to the TDI of another controller in a daisy-chain configuration, the *IEEE Standard 1149.1* expects the value on TDO to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDO pin is enabled after reset, assuring that the pin remains at a constant logic level when the JTAG port is not being used. The internal pull-up and pull-down resistors can be turned off to save internal power if a High-Z output value is acceptable during certain TAP controller states (see page 777 and page 779).

**Note:** If the device fails initialization during reset, the hardware toggles the TDO output as an indication of failure. Thus, during board layout, designers should not designate the TDO pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

#### 4.3.2 JTAG TAP Controller

The JTAG TAP controller state machine is shown in Figure 4-2. The TAP controller state machine is reset to the Test-Logic-Reset state on the assertion of a Power-On-Reset (POR). In order to reset the JTAG module after the microcontroller has been powered on, the TMS input must be held HIGH for five TCK clock cycles, resetting the TAP controller and all associated JTAG chains. Asserting the correct sequence on the TMS pin allows the JTAG module to shift in new instructions, shift in data, or idle during extended testing sequences. For detailed information on the function of the TAP controller and the operations that occur in each state, please refer to *IEEE Standard 1149.1*.

Figure 4-2. Test Access Port State Machine

### 4.3.3 Shift Registers

The Shift Registers consist of a serial shift register chain and a parallel load register. The serial shift register chain samples specific information during the TAP controller's CAPTURE states and allows this information to be shifted out on TD0 during the TAP controller's SHIFT states. While the sampled data is being shifted out of the chain on TD0, new data is being shifted into the serial shift register on TDI. This new data is stored in the parallel load register during the TAP controller's UPDATE states. Each of the shift registers is discussed in detail in "Register Descriptions" on page 221.

### 4.3.4 Operational Considerations

Certain operational parameters must be considered when using the JTAG module. Because the JTAG pins can be programmed to be GPIOs, board configuration and reset conditions on these pins must be considered. In addition, because the JTAG module has integrated ARM Serial Wire Debug, the method for switching between these two operational modes is described below.

#### 4.3.4.1 GPIO Functionality

When the microcontroller is reset with either a POR or RST, the JTAG/SWD port pins default to their JTAG/SWD configurations. The default configuration includes enabling digital functionality (DEN[3:0] set in the **Port C GPIO Digital Enable (GPIODEN)** register), enabling the pull-up resistors (PUE[3:0] set in the **Port C GPIO Pull-Up Select (GPIOPUR)** register), disabling the pull-down resistors (PDE[3:0] cleared in the **Port C GPIO Pull-Down Select (GPIOPDR)** register) and enabling the

alternate hardware function (AFSEL[3:0] set in the **Port C GPIO Alternate Function Select (GPIOAFSEL)** register) on the JTAG/SWD pins. See page 771, page 777, page 779, and page 782.

It is possible for software to configure these pins as GPIOs after reset by clearing AFSEL[3:0] in the **Port C GPIOAFSEL** register. If the user does not require the JTAG/SWD port for debugging or board-level testing, this provides four more GPIOs for use in the design.

**Caution** – It is possible to create a software sequence that prevents the debugger from connecting to the TM4C129DNCPDT microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger. In the case that the software routine is not implemented and the device is locked out of the part, this issue can be solved by using the TM4C129DNCPDT Flash Programmer "Unlock" feature. Please refer to [LMFLASHPROGRAMMER](#) on the TI web for more information.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the NMI pin (see "Signal Tables" on page 1825 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 771), **GPIO Pull Up Select (GPIOPUR)** register (see page 777), **GPIO Pull-Down Select (GPIOPDR)** register (see page 779), and **GPIO Digital Enable (GPIODEN)** register (see page 782) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 784) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 785) have been set.

#### 4.3.4.2 Communication with JTAG/SWD

Because the debug clock and the system clock can be running at different frequencies, care must be taken to maintain reliable communication with the JTAG/SWD interface. In the Capture-DR state, the result of the previous transaction, if any, is returned, together with a 3-bit ACK response. Software should check the ACK response to see if the previous operation has completed before initiating a new transaction. Alternatively, if the system clock is at least 8 times faster than the debug clock (TCK or SWCLK), the previous operation has enough time to complete and the ACK bits do not have to be checked.

#### 4.3.4.3 Recovering a "Locked" Microcontroller

**Note:** Performing the sequence below restores the non-volatile registers discussed in "Non-Volatile Register Programming-- Flash Memory Resident Registers" on page 613 to their factory default values. The mass erase of the Flash memory caused by the sequence below occurs prior to the non-volatile registers being restored.

In addition, the EEPROM is erased and its wear-leveling counters are returned to factory default values when performing the sequence below.

If software configures any of the JTAG/SWD pins as GPIO and loses the ability to communicate with the debugger, there is a debug port unlock sequence that can be used to recover the microcontroller. Performing a total of ten JTAG-to-SWD and SWD-to-JTAG switch sequences while holding the microcontroller in reset mass erases the Flash memory. The debug port unlock sequence is:

1. Assert and hold the RST signal.
2. Apply power to the device.

3. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence on the section called “JTAG-to-SWD Switching” on page 220.
4. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence on the section called “SWD-to-JTAG Switching” on page 221.
5. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
6. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
7. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
8. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
9. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
10. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
11. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
12. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
13. Release the RST signal.
14. Wait 400 ms.
15. Power-cycle the microcontroller.

#### 4.3.4.4 ARM Serial Wire Debug (SWD)

In order to seamlessly integrate the ARM Serial Wire Debug (SWD) functionality, a serial-wire debugger must be able to connect to the Cortex-M4F core without having to perform, or have any knowledge of, JTAG cycles. This integration is accomplished with a SWD preamble that is issued before the SWD session begins.

The switching preamble used to enable the SWD interface of the SWJ-DP module starts with the TAP controller in the Test-Logic-Reset state. From here, the preamble sequences the TAP controller through the following states: Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, and Test Logic Reset states.

Stepping through this sequence of the TAP state machine enables the SWD interface and disables the JTAG interface. For more information on this operation and the SWD interface, see the *ARM® Debug Interface V5 Architecture Specification*.

Because this sequence is a valid series of JTAG operations that could be issued, the ARM JTAG TAP controller is not fully compliant to the *IEEE Standard 1149.1*. This instance is the only one where the ARM JTAG TAP controller does not meet full compliance with the specification. Due to the low probability of this sequence occurring during normal operation of the TAP controller, it should not affect normal performance of the JTAG interface.

#### **JTAG-to-SWD Switching**

To switch the operating mode of the Debug Access Port (DAP) from JTAG to SWD mode, the external debug hardware must send the switching preamble to the microcontroller. The 16-bit TMS/SWDIO command for switching to SWD mode is defined as b1110.0111.1001.1110, transmitted LSB first. This command can also be represented as 0xE79E when transmitted LSB first. The

complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset states.
2. Send the 16-bit JTAG-to-SWD switch command, 0xE79E, on TMS/SWDIO.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in SWD mode before sending the switch sequence, the SWD goes into the line reset state.

To verify that the Debug Access Port (DAP) has switched to the Serial Wire Debug (SWD) operating mode, perform a SWD READID operation. The ID value can be compared against the device's known ID to verify the switch.

### **SWD-to-JTAG Switching**

To switch the operating mode of the Debug Access Port (DAP) from SWD to JTAG mode, the external debug hardware must send a switch command to the microcontroller. The 16-bit TMS/SWDIO command for switching to JTAG mode is defined as b1110.0111.0011.1100, transmitted LSB first. This command can also be represented as 0xE73C when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset states.
2. Send the 16-bit SWD-to-JTAG switch command, 0xE73C, on TMS/SWDIO.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in JTAG mode before sending the switch sequence, the JTAG goes into the Test Logic Reset state.

To verify that the Debug Access Port (DAP) has switched to the JTAG operating mode, set the JTAG Instruction Register (IR) to the IDCODE instruction and shift out the Data Register (DR). The DR value can be compared against the device's known IDCODE to verify the switch.

## **4.4 Initialization and Configuration**

After a Power-On-Reset or an external reset (RST), the JTAG pins are automatically configured for JTAG communication. No user-defined initialization or configuration is needed. However, if the user application changes these pins to their GPIO function, they must be configured back to their JTAG functionality before JTAG communication can be restored. To return the pins to their JTAG functions, enable the four JTAG pins (PC[3:0]) for their alternate function using the **GPIOAFSEL** register. In addition to enabling the alternate functions, any other changes to the GPIO pad configurations on the four JTAG pins (PC[3:0]) should be returned to their default settings.

## **4.5 Register Descriptions**

The registers in the JTAG TAP Controller or Shift Register chains are not memory mapped and are not accessible through the on-chip Advanced Peripheral Bus (APB). Instead, the registers within the JTAG controller are all accessed serially through the TAP Controller. These registers include the Instruction Register and the six Data Registers.

### 4.5.1 Instruction Register (IR)

The JTAG TAP Instruction Register (IR) is a four-bit serial scan chain connected between the JTAG TDI and TD0 pins with a parallel load register. When the TAP Controller is placed in the correct states, bits can be shifted into the IR. Once these bits have been shifted into the chain and updated, they are interpreted as the current instruction. The decode of the IR bits is shown in Table 4-3. A detailed explanation of each instruction, along with its associated Data Register, follows.

**Table 4-3. JTAG Instruction Register Commands**

| IR[3:0]    | Instruction      | Description                                                                                                                        |
|------------|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 0x0        | EXTEST           | Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction onto the pads.                          |
| 0x2        | SAMPLE / PRELOAD | Captures the current I/O values and shifts the sampled values out of the Boundary Scan Chain while new preload data is shifted in. |
| 0x8        | ABORT            | Shifts data into the ARM Debug Port Abort Register.                                                                                |
| 0xA        | DPACC            | Shifts data into and out of the ARM DP Access Register.                                                                            |
| 0xB        | APACC            | Shifts data into and out of the ARM AC Access Register.                                                                            |
| 0xE        | IDCODE           | Loads manufacturing information defined by the <i>IEEE Standard 1149.1</i> into the IDCODE chain and shifts it out.                |
| 0xF        | BYPASS           | Connects TDI to TD0 through a single Shift Register chain.                                                                         |
| All Others | Reserved         | Defaults to the BYPASS instruction to ensure that TDI is always connected to TD0.                                                  |

#### 4.5.1.1 EXTEST Instruction

The EXTEST instruction is not associated with its own Data Register chain. Instead, the EXTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the EXTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the outputs and output enables are used to drive the GPIO pads rather than the signals coming from the core. With tests that drive known values out of the controller, this instruction can be used to verify connectivity. While the EXTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

#### 4.5.1.2 SAMPLE/PRELOAD Instruction

The SAMPLE/PRELOAD instruction connects the Boundary Scan Data Register chain between TDI and TD0. This instruction samples the current state of the pad pins for observation and preloads new test data. Each GPIO pad has an associated input, output, and output enable signal. When the TAP controller enters the Capture DR state during this instruction, the input, output, and output-enable signals to each of the GPIO pads are captured. These samples are serially shifted out on TD0 while the TAP controller is in the Shift DR state and can be used for observation or comparison in various tests.

While these samples of the inputs, outputs, and output enables are being shifted out of the Boundary Scan Data Register, new data is being shifted into the Boundary Scan Data Register from TDI. Once the new data has been shifted into the Boundary Scan Data Register, the data is saved in the parallel load registers when the TAP controller enters the Update DR state. This update of the parallel load register preloads data into the Boundary Scan Data Register that is associated with each input, output, and output enable. This preloaded data can be used with the EXTEST instruction to drive data into or out of the controller. See “Boundary Scan Data Register” on page 224 for more information.

#### 4.5.1.3 ABORT Instruction

The ABORT instruction connects the associated ABORT Data Register chain between TDI and TDO. This instruction provides read and write access to the ABORT Register of the ARM Debug Access Port (DAP). Shifting the proper data into this Data Register clears various error bits or initiates a DAP abort of a previous request. See the “ABORT Data Register” on page 225 for more information.

#### 4.5.1.4 DPACC Instruction

The DPACC instruction connects the associated DPACC Data Register chain between TDI and TDO. This instruction provides read and write access to the DPACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to the ARM debug and status registers. See “DPACC Data Register” on page 225 for more information.

#### 4.5.1.5 APACC Instruction

The APACC instruction connects the associated APACC Data Register chain between TDI and TDO. This instruction provides read and write access to the APACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to internal components and buses through the Debug Port. See “APACC Data Register” on page 224 for more information.

#### 4.5.1.6 IDCODE Instruction

The IDCODE instruction connects the associated IDCODE Data Register chain between TDI and TDO. This instruction provides information on the manufacturer, part number, and version of the ARM core. This information can be used by testing equipment and debuggers to automatically configure input and output data streams. IDCODE is the default instruction loaded into the JTAG Instruction Register when a Power-On-Reset (POR) is asserted, or the Test-Logic-Reset state is entered. See “IDCODE Data Register” on page 223 for more information.

#### 4.5.1.7 BYPASS Instruction

The BYPASS instruction connects the associated BYPASS Data Register chain between TDI and TDO. This instruction is used to create a minimum length serial path between the TDI and TDO ports. The BYPASS Data Register is a single-bit shift register. This instruction improves test efficiency by allowing components that are not needed for a specific test to be bypassed in the JTAG scan chain by loading them with the BYPASS instruction. See “BYPASS Data Register” on page 224 for more information.

### 4.5.2 Data Registers

The JTAG module contains six Data Registers. These serial Data Register chains include: IDCODE, BYPASS, Boundary Scan, APACC, DPACC, and ABORT and are discussed in the following sections.

#### 4.5.2.1 IDCODE Data Register

The format for the 32-bit IDCODE Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-3. The standard requires that every JTAG-compliant microcontroller implement either the IDCODE instruction or the BYPASS instruction as the default instruction. The LSB of the IDCODE Data Register is defined to be a 1 to distinguish it from the BYPASS instruction, which has an LSB of 0. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

The major uses of the JTAG port are for manufacturer testing of component assembly and program development and debug. To facilitate the use of auto-configuration debug tools, the IDCODE instruction outputs a value of 0x4BA0.0477. This value allows the debuggers to automatically configure themselves to work correctly with the Cortex-M4F during debug.

**Figure 4-3. IDCODE Register Format**

#### 4.5.2.2 BYPASS Data Register

The format for the 1-bit BYPASS Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-4. The standard requires that every JTAG-compliant microcontroller implement either the BYPASS instruction or the IDCODE instruction as the default instruction. The LSB of the BYPASS Data Register is defined to be a 0 to distinguish it from the IDCODE instruction, which has an LSB of 1. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

**Figure 4-4. BYPASS Register Format**

#### 4.5.2.3 Boundary Scan Data Register

The format of the Boundary Scan Data Register is shown in Figure 4-5. Each GPIO pin, starting with a GPIO pin next to the JTAG port pins, is included in the Boundary Scan Data Register. Each GPIO pin has three associated digital signals that are included in the chain. These signals are input, output, and output enable, and are arranged in that order as shown in the figure.

When the Boundary Scan Data Register is accessed with the SAMPLE/PRELOAD instruction, the input, output, and output enable from each digital pad are sampled and then shifted out of the chain to be verified. The sampling of these values occurs on the rising edge of TCK in the Capture DR state of the TAP controller. While the sampled data is being shifted out of the Boundary Scan chain in the Shift DR state of the TAP controller, new data can be preloaded into the chain for use with the EXTEST instruction. The EXTEST instruction forces data out of the controller.

**Figure 4-5. Boundary Scan Register Format**

#### 4.5.2.4 APACC Data Register

The format for the 35-bit APACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

#### **4.5.2.5 DPACC Data Register**

The format for the 35-bit DPACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

#### **4.5.2.6 ABORT Data Register**

The format for the 35-bit ABORT Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

## 5 System Control

System control configures the overall operation of the device and provides information about the device. Configurable features include reset control, NMI operation, power control, clock control, and low-power modes.

### 5.1 Signal Description

The following table lists the external signals of the System Control module and describes the function of each. The NMI signal is the alternate function for two GPIO signals, which default to GPIO after reset. The NMI pins are under commit protection and require a special process to be configured as any alternate function or to subsequently return to the GPIO function. See “Commit Control” on page 753 for more information. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the NMI signal. The number in parentheses next to the pin placement listed is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 788) to assign the NMI signal to the specified GPIO port pin. In addition, the AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 771) should be set to choose the NMI function. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 742. The remaining signals listed in the table (with the word “fixed” in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

**Table 5-1. System Control & Clocks Signals (128TQFP)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                                                                                                                                   |
|----------|------------|--------------------------|----------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| DIVSCLK  | 102        | PQ4 (7)                  | O        | TTL         | An optionally divided reference clock output based on a selected clock source. Note that this signal is not synchronized to the System Clock. |
| NMI      | 128        | PD7 (8)                  | I        | TTL         | Non-maskable interrupt.                                                                                                                       |
| OSC0     | 88         | fixed                    | I        | Analog      | Main oscillator crystal input or an external clock reference input.                                                                           |
| OSC1     | 89         | fixed                    | O        | Analog      | Main oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                     |
| RST      | 70         | fixed                    | I        | TTL         | System reset input.                                                                                                                           |

### 5.2 Functional Description

The System Control module provides the following capabilities:

- Device identification, see “Device Identification” on page 226
- Configurable control of reset, power, and clock sources.
- System control (Run, Sleep, and Deep-Sleep modes), see “System Control” on page 245

#### 5.2.1 Device Identification

Read-only registers in the system control module provide information about the microcontroller, such as version, part number, pin count, operating temperature range and available peripherals on the device. The **Device Identification 0 (DID0)** (page 261) and **Device Identification 1 (DID1)** (page 263) registers provide details about the device's version, package, temperature range, and so on. The Peripheral Present registers starting at system control offset 0x300, such as the **Watchdog**

**Timer Peripheral Present (PPWD)** register, provide information on how many of each type of module are included on the device. Finally, information about the capabilities of the on-chip peripherals are provided at offset 0xFC0 in each peripheral's register space in the Peripheral Properties registers, such as the **GPTM Peripheral Properties (GPTMPP)**. In addition, there are four unique identifier registers, **Unique Identifier n (UNIQUEIDn)**, that provide a 128-bit unique identifier for each device that cannot be modified.

## 5.2.2 Reset Control

This section discusses aspects of hardware functions during reset as well as system software requirements following the reset sequence.

### 5.2.2.1 Reset Sources

The TM4C129DNCPDT microcontroller has the following reset sources:

1. Power-on reset (POR) (see page 228).
2. External reset input pin (RST) assertion (see page 229).
3. A brown-out detection of  $V_{DDA}$  (analog voltage source) or  $V_{DD}$  (external voltage source) dropping below its acceptable operating range. (see page 230).
4. Software-initiated reset (with the software reset registers) (see page 232).
5. A watchdog timer reset condition violation (see page 232).
6. Hibernation module event
7. A software restart initiated through a Hardware System Service Request (HSSR)
8. MOSC failure (see page 234).

Table 5-2 provides a summary of results of the various reset operations. Note that the external RST pin, the Brown-out detection unit, the HIB module and watchdog timer can all be programmed to generate either a Power-On Reset (POR) or system reset depending on how the **Reset Behavior Control (RESBEHAVCTL)** register at offset 0x1D8 is programmed.

**Table 5-2. Reset Sources**

| Reset Source                                                                        | Core Reset? | JTAG Reset?            | On-Chip Peripherals Reset? |
|-------------------------------------------------------------------------------------|-------------|------------------------|----------------------------|
| Externally Generated Power-On Reset                                                 | Yes         | Yes                    | Yes                        |
| RST pin Power-On Reset                                                              | Yes         | Pin Configuration Only | Yes                        |
| RST pin System Reset                                                                | Yes         | Pin Configuration Only | Yes                        |
| Brown-Out Power-On Reset                                                            | Yes         | Pin Configuration Only | Yes                        |
| Brown-Out System Reset                                                              | Yes         | Pin Configuration Only | Yes                        |

| Software System Reset Request using the VECTRESET bit in the <b>APINT</b> register. | Yes         | No                     | No                         |

Table 5-2. Reset Sources (*continued*)

| Reset Source              | Core Reset? | JTAG Reset?            | On-Chip Peripherals Reset? |
|---------------------------|-------------|------------------------|----------------------------|
| Software Peripheral Reset | No          | Pin Configuration Only | Yes <sup>a</sup>           |
| Watchdog Power-On Reset   | Yes         | Pin Configuration Only | Yes                        |
| Watchdog System Reset     | Yes         | Pin Configuration Only | Yes                        |
| HIB Module Power-On Reset | Yes         | Pin Configuration Only | Yes                        |
| HIB Module System Reset   | Yes         | Pin Configuration Only | Yes                        |
| HSSR Reset                | Yes         | Pin Configuration Only | Yes                        |
| MOSC Failure Reset        | Yes         | Pin Configuration Only | Yes                        |

a. Programmable on a module-by-module basis by using the individual peripheral Software Reset Registers starting at System Control offset 0x500

After a reset, the **Reset Cause (RESC)** register is set with the reset cause. The bits in this register are sticky and maintain their state across multiple reset sequences. A bit in the **RESC** register can be cleared by writing a 0.

### 5.2.2.2 Boot Configuration

After Power-On-Reset (POR) and device initialization occurs, the hardware loads the stack pointer from either flash or ROM based on the presence of an application in flash and the state of the EN bit in the **BOOTCFG** register. If the flash address 0x0000.0004 contains an erased word (value 0xFFFF.FFFF) or the EN bit of the **BOOTCFG** register is clear, the stack pointer and reset vector pointer are loaded from ROM at address 0x0100.0000 and 0x0100.0004, respectively. The boot loader executes and configures the available boot slave interfaces and waits for an external memory to load its software.

If the check of the Flash at address 0x0000.0004 contains a valid reset vector value and the **BOOTCFG** register does not indicate the boot loader, the boot sequence causes the stack pointer/reset vector fetch from Flash. This application stack pointer and reset vector is loaded and the processor executes the application directly.

**Note:** If the device fails the initialization phase, it toggles the TDO output pin as an indication the device is not executing. This feature is provided for debug purposes.

### 5.2.2.3 Externally Generated Power-On Reset (POR)

**Note:** The JTAG controller can be reset by a power-on reset or by holding the TMS pin to high for 5 clock cycles.

During an externally generated POR, the internal Power-On Reset (POR) circuit monitors the power supply voltage ( $V_{DD}$ ) and generates a reset signal to all of the internal logic including JTAG when the power supply ramp reaches a threshold value ( $V_{POR}$ ). Reset does not complete if specific voltage parameters are not met as defined in the Electrical Characteristics chapter. For applications that require the use of an external reset signal to hold the microcontroller in reset longer than the internal POR, the RST input may be used as discussed in “External  $\overline{RST}$  Pin” on page 229. Holding this pin active can keep the initialization process from starting even though power-on reset has occurred. This is useful in in-circuit testing and other situations where it is desirable to delay the operation of the device until an external supervisor has released.

The Power-On Reset sequence is as follows:

1. The microcontroller waits for internal POR to go inactive.

2. The internal reset is released and the core executes a full initialization of the device. Upon completion, the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The internal POR is only active on the initial power-up of the microcontroller, when the microcontroller wakes from hibernation, and when the VDD supply drops below the its defined operating limit. Please refer to the Electrical Characteristics chapter for information on exact values. The Power-On Reset timing is shown in “Power and Brown-Out” on page 1882.

#### 5.2.2.4 External RST Pin

When the external RST pin is asserted it initiates a system reset or Power-On Reset depending on what has been configured in the **Reset Behavior Control (RESBEHAVCTL)** Register. If the EXTRES bit field in **RESBEHAVCTL** is set to 0x3 then a simulated full initialization will begin upon RST assertion. If these bits are programmed to 0x2 then a system reset is issued. When EXTRES is set to a 0x0 or 0x1, then the external RST pin performs its default operation upon assertion, which is issuing a full simulated POR.

An external reset pin (RST) that is configured to generate a Power-On Reset resets the microcontroller including the core and all the on-chip peripherals. The external reset sequence is as follows:

1. The external reset pin (RST) is asserted for the duration specified by  $T_{MIN}$  and then deasserted (see “Reset” on page 1887). This generates an internal POR signal.
2. The microcontroller waits for internal POR to go inactive.
3. The internal reset is released and the core executes a full initialization of the device. Upon completion, the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution. Refer to “Reset” on page 1887 for internal reset deassertion timing.

An external reset pin (RST) that is configured to generate a system reset will reset the microcontroller including the core and all the on-chip peripherals. The external reset sequence is as follows:

1. The external reset pin (RST) is asserted for the duration specified by  $T_{MIN}$  and then deasserted (see “Reset” on page 1887).
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

**Note:** It is recommended that the trace for the RST signal must be kept as short as possible. Be sure to place any components connected to the RST signal as close to the microcontroller as possible.

If the application only uses the internal POR circuit, the RST input must be connected to the power supply ( $V_{DD}$ ) through an optional pull-up resistor (0 to 100K  $\Omega$ ) as shown in Figure 5-1 on page 230. The RST input has filtering which requires a minimum pulse width in order for the reset pulse to be recognized, see Table 30-14 on page 1887.

To improve noise immunity and/or to delay reset at power up, the RST input may be connected to an RC network as shown in Figure 5-2 on page 230. If the application requires the use of an external reset switch, Figure 5-3 on page 230 shows the proper circuitry to use. In the figures, the  $R_{PU}$  and  $C_1$  components define the power-on delay. The external reset timing is shown in Figure 30-11 on page 1888.

**Figure 5-1. Basic  $\overline{\text{RST}}$  Configuration**

**Note:**  $R_{PU} = 0$  to 100 k $\Omega$

**Figure 5-2. External Circuitry to Extend Power-On Reset**

**Note:**  $R_{PU} = 1$  k $\Omega$  to 100 k $\Omega$

$C_1 = 1$  nF to 10  $\mu$ F

**Figure 5-3. Reset Circuit Controlled by Switch**

**Note:** Typical  $R_{PU} = 10$  k $\Omega$

Typical  $R_S = 470$   $\Omega$

$C_1 = 10$  nF

### 5.2.2.5 Brown-Out Reset (BOR)

The microcontroller provides a brown-out detection circuit that triggers if the  $V_{DD}$  (external) or  $V_{DDA}$  (analog) power supply drops below its corresponding brown-out threshold voltage. If a brown-out condition is detected, the system may generate an interrupt, a system reset or a Power-On Reset. The default value at reset is to generate an interrupt.

The application can identify the type of BOR event that occurred by reading the **Power-Temperature Cause (PWRTC)** register. The BOR detection circuits can be programmed to generate a reset, System Control interrupt, or NMI in the **Power-Temp Brown Out Control (PTBOCTL)** register. The default settings at reset are as follows:

- $V_{DDA}$  under BOR detection default setting is for no action to occur.
- $V_{DD}$  under BOR detection default setting is to execute a full POR.

If the user has programmed a field in the **PTBOCTL** to generate a reset, then the BOR bit of the **Reset Behavior Control (RESBEHAVCTL)** register can be programmed to further define what type of reset is generated. If the BOR field is programmed to 0x3, a full POR is initiated; if is set to 0x2, then a system reset is issued. When the BOR field is set to a 0x0 or 0x1, then the Brown-Out detection circuit will perform its default operation upon assertion, which is issuing an interrupt.

**Note:**  $V_{DDA}$  BOR and  $V_{DD}$  BOR events are a combined BOR to the system logic, such that if either BOR event occurs, the following bits are affected:

- BORRIS bit in the **Raw Interrupt Status (RIS)** register, System Control offset 0x050. See page 267.
- BORMIS bit in the **Masked Interrupt Status and Clear (MISC)** register, System Control offset 0x058. This bit is set only if the BORIM bit in the **Interrupt Mask Control (IMC)** register has been set. See page 269 and page 271.
- BOR bit in the **Reset Cause (RESC)** register, System Control offset 0x05C. This bit is set only if either of the BOR events have been configured to initiate a reset. See page 273.

In addition, the following bits control both BOR events:

- BORIM bit in the **Interrupt Mask Control (IMC)** register, System Control offset 0x054.
- $VDDA\_UBOR0$  and  $VDD\_UBOR0$  bits in the **Power-Temperature Cause (PWRTC)** register.

Please refer to “System Control” on page 226 for more information on how to configure these registers.

The brown-out POR reset sequence is as follows:

1. When one of the BOR event triggers occurs, an internal Brown-Out Reset condition is set.
2. If the BOR event has been programmed to generate a reset in the **PTBOCTL** register and the BOR bit of the **RESBEHAVCTL** has been set to 0x3, an internal POR reset is asserted.
3. The internal reset is released and the core executes a full initialization of the device. Upon completion, the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution. The application starts after deassertion of internal POR. Refer to “Reset” on page 1887 for BOR internal reset deassertion timing.

The brown-out system reset sequence is as follows:

1. When one of the BOR event triggers occurs, an internal Brown-Out Reset condition is set.
2. If the BOR event has been programmed to generate a reset in the **PTBOCTL** register and the BOR bit of the **RESBEHAVCTL** has been set to 0x2, an internal reset is asserted.

3. The internal reset is released and the microcontroller fetches and loads the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.

The result of a brown-out reset is equivalent to that of an assertion of the external RST input, and the reset is held active until the proper voltage level is restored. The **RESC** register can be examined in the reset interrupt handler to determine if a Brown-Out condition was the cause of the reset, thus allowing software to determine what actions are required to recover.

The internal Brown-Out Reset timing is shown in “Power and Brown-Out” on page 1882.

#### 5.2.2.6 Software Reset

Software can reset a specific peripheral or generate a reset to the entire microcontroller.

Peripherals can be individually reset by software via peripheral-specific reset registers available beginning at System Control offset 0x500 (for example the **Watchdog Timer Software Reset (SRWD)** register page 360). If the bit position corresponding to a peripheral is set and subsequently cleared, the peripheral is reset.

The entire microcontroller, including the core, can be reset by software by setting the SYSRESREQ bit in the **Application Interrupt and Reset Control (APINT)** register in the core peripheral memory map space. The software-initiated system reset sequence is as follows:

1. A software microcontroller reset is initiated by setting the SYSRESREQ bit.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The core only can be reset by software by setting the VECTRESET bit in the **APINT** register. The software-initiated core reset sequence is as follows:

1. A core reset is initiated by setting the VECTRESET bit.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The software-initiated system reset timing is shown in Figure 30-12 on page 1888.

#### 5.2.2.7 Watchdog Timer Reset

The Watchdog Timer module's function is to prevent system hangs. The TM4C129DNCNPD microcontroller has two Watchdog Timer modules in case one watchdog clock source fails. One watchdog is run off the system clock and the other is run off the Precision Internal Oscillator (PIOSC). The watchdog timer can be configured to generate an interrupt or a non-maskable interrupt to the microcontroller on its first time-out and to generate a system reset or power-on reset on its second time-out.

After the watchdog's first time-out event, the 32-bit watchdog counter is reloaded with the value of the **Watchdog Timer Load (WDTLOAD)** register and resumes counting down from that value. If the timer counts down to zero again before the first time-out interrupt is cleared, and watchdog reset

generation has been enabled through the RESEN bit in the **Watchdog Control Register (WDTCTL)**, the watchdog timer asserts its reset signal to the microcontroller. The reset generated can be a full Power-On Reset or a system reset depending on the value programmed in WDOGn bit field of the **Reset Behavior Control Register (RESBEHAVCTL)**. If the RESEN bit of the **WDTCTL** register is set to 1 and the WDOGn bit field of the **RESBEHAVCTL** register is programmed to 0x3 a full POR is initiated; if WDOGn set to 0x2, then a system reset is issued. When WDOGn is set to a 0x0 or 0x1, then the watchdog time performs its default operation upon assertion, which is issuing a full POR.

The watchdog timer Power-On Reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal POR reset is asserted.
3. The internal reset is released and the core executes a full initialization of the device. Upon completion, the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution. Refer to “Reset” on page 1887 for watchdog timeout internal reset deassertion timing.

The watch dog timer system reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal reset is asserted.
3. The internal reset is released and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

For more information on the Watchdog Timer module, see “Watchdog Timers” on page 1145.

The watchdog reset timing is shown in Figure 30-13 on page 1888.

#### 5.2.2.8 Hibernation Module Reset

When the Hibernation module has been configured and powered by an initial "cold" POR and is subsequently put into hibernation mode, a wake event (not including an external reset pin wake) causes the module to generate a system reset. This reset signal resets all circuitry on the device with the exception of the Hibernation module. All Hibernation module registers retain their values after this reset.

When the Hibernation module receives a wake event and  $V_{DD}$  is enabled, a system reset sequence occurs as follows:

1. The POR or EXT bit in the **RESC** register is set.
2. An internal reset is asserted.
3. The internal reset is released and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.
4. The **HIBRIS** register in the Hibernation module can be read to determine the cause of the reset.
5. The POR or EXT bit in the **RESC** register is cleared by writing a 0.

### 5.2.2.9 HSSR Reset

The **Hardware System Service Request (HSSR)** register can be used to restore the device back to factory settings. A successful write to the **Hardware System Service Request (HSSR)** register initiates a system reset. The reset initialization process executes before examining the **HSSR** register and processing the command. This register can only be accessed in privileged mode.

Before the return-to-factory settings routine has completed, a system reset sequence executes and the HSSR bit in the **RESC** register is set. After the HSSR function has been processed, the CD0FF field in the **HSSR** register is written with the outcome of the function processing and another HSSR system reset is executed. The HSSR bit can be cleared in the **RESC** register by writing a 0.

For more information regarding use of the **HSSR** register, refer to “Hardware System Service Request” on page 251.

## 5.2.3 Non-Maskable Interrupt

The microcontroller has multiple sources of non-maskable interrupt (NMI):

- The assertion of the NMI signal.
- A main oscillator verification error.
- The NMISSET bit in the **Interrupt Control and State (INTCTRL)** register in the Cortex™-M4F (see page 173).
- The Watchdog module time-out interrupt when the INTTYPE bit in the **Watchdog Control (WDTCTL)** register is set (see page 1151).
- Tamper event (see “Hibernation Module” on page 531 for more information).
- Any of the following BOR trigger events:
  - $V_{DDA}$  under BOR setting
  - $V_{DD}$  under BOR setting

Software must check the cause of the interrupt in the **NMI Cause (NMIC)** register in order to distinguish among the sources.

### 5.2.3.1 NMI Pin

The NMI signal is an alternate function for the GPIO port pin(s) specified in Table 29-3 on page 1839.

The alternate function must be enabled in the GPIO for the signal to be used as an interrupt, as described in “General-Purpose Input/Outputs (GPIOs)” on page 742. Note that enabling the NMI alternate function requires the use of the GPIO lock and commit function, similar to the requirements of the GPIO port pins associated with JTAG/SWD functionality, see page 785. The active sense of the NMI signal is High; asserting the enabled NMI signal above  $V_{IH}$  initiates the NMI interrupt sequence.

### 5.2.3.2 Main Oscillator Verification Failure

The TM4C129DNCPT microcontroller provides a main oscillator verification circuit that generates an error condition if the oscillator is running too fast or too slow. If the main oscillator verification circuit is enabled and a failure occurs, either a power-on reset is generated and control is transferred to the NMI handler, or an interrupt is generated. The MOSCIM bit in the **MOSCCTL** register determines

which action occurs. In either case, the system clock source is automatically switched to the PIOSC. If a MOSC failure reset occurs, the NMI handler is used to address the main oscillator verification failure because the necessary code can be removed from the general reset handler, speeding up reset processing. The detection circuit is enabled by setting the CVAL bit in the **Main Oscillator Control (MOSCCTL)** register. The main oscillator verification error is indicated in the main oscillator fail status (MOSCFAIL) bit in the **Reset Cause (RESC)** register. The main oscillator verification circuit action is described in more detail in the section called “Main Oscillator Verification Circuit” on page 243.

## 5.2.4 Power Control

The TM4C129DNCPDT microcontroller provides an integrated LDO regulator that is used to provide power to the majority of the microcontroller's internal logic. Figure 5-4 shows the power architecture. The voltage output has a maximum voltage of 1.2 V. Refer to “Dynamic Power Management” on page 248 for more information on the LDO operation.

An external LDO may not be used.

**Note:** VDDA must be supplied with 3.3 V, or the microcontroller does not function properly. VDDA is the supply for all of the analog circuitry on the device, including the clock circuitry.

**Figure 5-4. Power Architecture**

**Note:** The V<sub>DDA</sub> voltage source is typically connected to a filtered voltage source or regulator.

## 5.2.5 Clock Control

The system control module determines the control of clocks in this part.

### 5.2.5.1 Fundamental Clock Sources

There are multiple clock sources for use in the microcontroller. The **Run and Sleep Mode Configuration Register (RSCLKCFG)** can be used to configure the required clock source for the device after Power-On Reset, as well as the system clock divisor encodings. The available clock sources are as follows:

- **Precision Internal Oscillator (PIOSC).** The precision internal oscillator is an on-chip clock source that the microcontroller uses during and following POR. It is the clock source in effect at the start of reset vector fetch and the start of code application execution. It does not require the use of any external components and provides a clock that is  $16\text{ MHz} \pm F_{\text{PIOSC}}$  across temperature (see Table 30-19 on page 1893). The PIOSC allows for a reduced system cost in applications that require an accurate enough clock source. If the main oscillator is required, software must enable the main oscillator following reset and allow the main oscillator to stabilize before changing the clock reference. If the Hibernation Module clock source is a 32.768-kHz oscillator, the precision internal oscillator can be trimmed by software based on a reference clock for increased accuracy. Regardless of whether or not the PIOSC is the source for the system clock, the PIOSC can be configured to be an alternate clock source for some of the peripherals. See the section called “Peripheral Clock Sources” on page 240 for more information on peripherals that can use the PIOSC as an alternate clock.
- **Main Oscillator (MOSC).** The main oscillator provides a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins. If the PLL is being used, the crystal value can be any frequency between 5 MHz to 25 MHz (inclusive). Refer to Table 5-7 on page 244 for recommended crystal values and PLL register programming. If the PLL is not being used, the crystal may be any one of the supported frequencies between 4 MHz to 25 MHz. The single-ended clock source range is from DC through the specified speed of the microcontroller.
- **Low-Frequency Internal Oscillator (LFIOSC).** The Low-Frequency Internal Oscillator (LFIOSC) provides a nominal frequency of 33 kHz with percentage variance specified in the Electrical Characteristics section. It is intended for use during Deep-Sleep power-saving modes. This power-savings mode provides reduced internal switching and the ability to power down the MOSC and/or PIOSC while in Deep-Sleep mode through configuration of the **Deep Sleep Clock Configuration Register (DSCLKCFG)** register.
- **Hibernation Module RTC Oscillator (RTCOSC) Clock Source.** The Hibernation Module provides a muxed output of two clocks to the System Control Module, an external 32.768-kHz clock or a low-frequency clock (HIB LFIOSC). The Hibernation module has the option of being clocked by a 32.768-kHz oscillator connected to the XOSC0 pin. The 32.768-kHz oscillator can be used for the system clock, thus eliminating the need for an additional crystal or oscillator. Alternatively, the Hibernation module contains a low-frequency oscillator (HIB LFIOSC) which is intended to provide the system with a real-time clock source and may also provide an accurate source of Deep-Sleep or Hibernate mode power savings. Note that the HIB LFIOSC is a different clock source than the LFIOSC. Refer to the Electrical Characteristic Chapter for more information on frequency range.

The internal system clock (SysClk), is derived from any of the above sources. An internal PLL can also be used by the PIOSC or MOSC clock to generate the system clock and peripheral clocks. Table 5-3 on page 237 shows how the various clock sources can be used in a system.

**Table 5-3. Clock Source Options**

| Clock Source                                                                    | Drive PLL Capability? | PLL Enabled, RSCLKCFG Bit Encodings | SysClk generation capability? | SysClk generation enabled, RSCLKCFG Bit Encodings |
|---------------------------------------------------------------------------------|-----------------------|-------------------------------------|-------------------------------|---------------------------------------------------|
| Precision Internal Oscillator (PIOSC)                                           | Yes                   | USEPLL = 1, PLLSRC = 0x0            | Yes                           | USEPLL = 0, OSCSRC = 0x0                          |
| Main Oscillator (MOSC)                                                          | Yes                   | USEPLL = 1, PLLSRC = 0x3            | Yes                           | USEPLL = 0, OSCSRC = 0x3                          |
| Low Frequency Internal Oscillator (LFIOSC) <sup>a</sup>                         | No                    | -                                   | Yes                           | USEPLL = 0, OSCSRC = 0x2                          |
| Hibernation Module RTC Oscillator (RTCOSC). 32.768-kHz Oscillator or HIB LFIOSC | No                    | -                                   | Yes                           | USEPLL = 0, OSCSRC = 0x4                          |

a. LFIOSC frequency is characterized as 33 kHz nominal, 10 kHz minimum and 90 kHz maximum.

### 5.2.5.2 Clock Configuration

The **Run and Sleep Mode Configuration Register (RSCLKCFG)** provides control for the system clock in run and sleep mode. The **Deep Sleep Clock Configuration register (DSCLKCFG)** specifies the behavior of the clock system while in deep sleep mode. These registers control the following clock functionality:

- Source of system clock in run and sleep mode
- Source of system clock in deep-sleep mode
- Enabling/disabling of PLL-derived system clock
- Clock divisors for PLL or oscillator, depending on what is enabled
- Enabling of memory timing parameters for flash

Providing further configuration, the **PLL Frequency n (PLLREQn)** registers allow the PLL VCO frequency ( $f_{VCO}$ ) to be multiplied or divided by programmable values depending on the system clock speed required.

Table 5-4 on page 237 shows the state of the clock sources following a Power-On Reset.

**Table 5-4. Clock Source State Following POR**

| Clock Source | Power-On Reset State |
|--------------|----------------------|
| PLL          | Disabled/Powered Off |
| MOSC         | Disabled/Powered Off |
| LFIOSC       | Enabled              |
| PIOSC        | Enabled              |
| HIB RTCOSC   | Disabled             |

Figure 5-5 shows the logic for the main clock tree. The peripheral blocks are driven by the system clock signal and can be individually enabled/disabled.

**Note:** The clock sources in Figure 5-5 include a superset of peripherals available in the family. Some peripheral clock sources may not be present on your specific device.

Figure 5-5. Main Clock Tree

### **Peripheral Clock Sources**

In addition to the main clock tree described above, the ADC, USB, Ethernet, PWM, UART, and QSSI all have a Clock Control register in their register map at offset 0xFC8 that can be used to control the clock generation for the module.

### **ADC Clock Control**

The ADC digital block is clocked by the system clock and the ADC analog block is clocked from a separate conversion clock (ADC clock). The ADC clock frequency can be up to 32 MHz to generate a conversion rate of 2 Msps. A 16 MHz ADC clock provides a 1 Msps sampling rate. There are three sources for the ADC clock:

- The PLL VCO ( $f_{VCO}$ ) can be used if the CS bit field is 0x0 in the **ADC Clock Configuration (ADCCC)** register and the CLKDIV bit field is configured in the same register.
- The PIOSC can be used directly to provide a conversion rate near 1 Ms/s. To use the PIOSC, the CS field in the **ADCCC** register needs to be set to 0x1 and the ALTCLK field should be programmed to 0x0 in the **Alternate Clock Configuration (ALTCLKCFG)** register.
- The Main Oscillator (MOSC): The MOSC clock source must be 16 MHz for a 1 Msps conversion rate and 32 MHz for a 2 Msps conversion rate.

**Note:** If the ADC module is not using the PIOSC as the clock source, the system clock must be at least 16 MHz.

### **USB Clock Control**

When the USB module uses the integrated USB PHY, the MOSC must be the clock source, either with or without using the PLL, and the system clock must be at least 30 MHz. In addition, only integer divisors should be used to achieve the 60 MHz USB clock source. Fractional divisors may increase jitter and compromise USB function. The **USB Clock Control Register (USBCC)** register contains a CLKDIV bit field which can be programmed to specify the divisor used to reduce the PLL VCO output to the 60 MHz clock source required for the serialization/deserialization module of the USB controller.

In ULPI mode, if the clock source to the USB is internal, then the USB0CLK pin is an output to the external ULPI PHY. If the USB clock source is external then, the USB0CLK pin functions as an input from the external ULPI PHY.

### **Ethernet Clock Control**

Available clock sources are dependent on the interface chosen. The following sections describe the clock control for the various interfaces.

### **MII Interface Clocking**

Four clock inputs are driven into the Ethernet MAC when the MII configuration is enabled. The clocks are described as follows (see “MII Interface” on page 1526 for more information):

- Gated system clock (SysClk): The SysClk signal acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SysClk frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module.
- MOSC: A gated version of the MOSC clock is provided as the Precision Time Protocol (PTP) reference clock (PTPREF\_CLK). The MOSC clock source can be a single-ended source on the OSC0 pin or a crystal on the OSC0 and OSC1 pins. When advanced timestamping is used and

the Precision Timer Protocol (PTP) module has been enabled by setting the PTPCEN bit in the **EMACCC** register, the MOSC drives PTPREF\_CLK. PTPREF\_CLK has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. Refer to “IEEE 1588 and Advanced Timestamp Function” on page 1559 for more information.

- EN0RXCK: This clock signal is driven by the external PHY oscillator and is either 2.5 or 25 MHz depending on whether the device is operating at 10 Mbps or 100 Mbps.
- EN0TXCK: This clock signal is driven by the external PHY oscillator and is either 2.5 or 25 MHz depending on whether the device is operating at 10 Mbps or 100 Mbps.

### ***RMII Interface Clocking***

There are three clock sources that interface to the Ethernet MAC in an RMII configuration (see “RMII Interface” on page 1527 for more information):

- Gated system clock (SysClk): The SysClk signal acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SysClk frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module.
- MOSC: A gated version of the MOSC clock is provided as the Precision Time Protocol (PTP) reference clock (PTPREF\_CLK). The MOSC clock source can be a single-ended source on the OSC0 pin or a crystal on the OSC0 and OSC1 pins. When advanced timestamping is used and the PTP module has been enabled by setting the PTPCEN bit in the **EMACCC** register, the MOSC drives PTPREF\_CLK. PTPREF\_CLK has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. Refer to “IEEE 1588 and Advanced Timestamp Function” on page 1559 for more information.
- EN0REF\_CLK: When using RMII, a 50 MHz external reference clock must drive the EN0REF\_CLK input signal and the external PHY. Depending on the configuration of the FES bit in the **Ethernet MAC Configuration (EMACCFG)** register, the reference clock input (EN0REF\_CLK) is divided by 20 for 10 Mbps or 2 for 100 Mbps operation and used as the clock for receive and transmit data.

### ***PWM Clock Control***

The **PWMCC** register can be used to select the System Clock as the PWM clock source or a divided System Clock. For more information, see page 1800.

### ***Other Peripheral Clock Control***

In the UART and QSSI Clock Control Registers, users can choose between the system clock (SysClk), which is the default source for the baud clock, and an alternate clock. Note that there may be special considerations when configuring the baud clock.

### ***Optional Clock Output Signal (DIVSCLK)***

An optional clock output, DIVSCLK, is provided which can be used as a clock source to an external device but bears no timing relationship to other signals. Note that this signal is not synchronized to the System Clock. By programming the SRC field in the **Divisor and Source Clock Configuration (DIVSCLK)** register, the following clock outputs may be selected for DIVSCLK:

- System Clock
- PIOSC

### ■ MOSC

The DIV field in the **DIVSCLK** register controls the divided output clock frequency. The DIVSCLK signal is selected as an alternate function of a GPIO signal and has the same inherit electrical characteristics of a GPIO as listed in “Electrical Characteristics” on page 1874.

### System Clock Frequency

The system clock (SysClk) is the clock that is distributed to the processor and the integrated peripherals after clock gating. The SysClk frequency is based on the frequency of the clock source and the divisor factor. For example, if the PLL is not being used and the device is not in deep sleep mode, then the OSYSDIV bit field in the **RSCLKCFG** register is the divisor used to determine the system clock. If the PLL is being used, then PSYSDIV bit field in the **RSCLKCFG** register must be programmed as well as the values in the **PLLREQ0** and **PLLREQ1** registers. If the device is in deep sleep mode, then the **Deep Sleep Clock Configuration Register (DSCLKCFG)** can be programmed with the divisor bit field DSSYSDIV to modify the clock source frequency. Table 5-5 on page 242 shows the different system clock frequency calculations based on the operation mode, clock source and PLL encoding.

**Table 5-5. System Clock Frequency**

| Clock Mode   | USEPLL (RSCLKCFG)             | SYSClk Value                        | Divisor Factors Used                                                                              |
|--------------|-------------------------------|-------------------------------------|---------------------------------------------------------------------------------------------------|
| Run or Sleep | 1                             | $f_{VCO} / (\text{PSYSDIV} + 1)$    | PSYSDIV bit field in <b>RSCLKCFG</b> ; MINT, MDIV in <b>PLLREQ0</b> ; Q, N bits in <b>PLLREQ1</b> |
| Run or Sleep | 0                             | $f_{OSCLK} / (\text{OSYSDIV} + 1)$  | OSYSDIV bit field in <b>RSCLKCFG</b>                                                              |
| Deep Sleep   | PLL not enabled in Deep Sleep | $f_{OSCLK} / (\text{DSSYSDIV} + 1)$ | DSSYSDIV bit field in <b>DSCLKCFG</b>                                                             |

### 5.2.5.3 Precision Internal Oscillator Operation (PIOSC)

The microcontroller powers up with the PIOSC running. If another clock source is desired, the PIOSC must remain enabled because it is used for internal functions. The PIOSC can only be disabled during Deep-Sleep mode. It can be powered down by setting the PIOSCPD bit in the **DSCLKCFG** register.

The PIOSC generates a 16-MHz clock with a  $\pm F_{PIOSC}$  accuracy (see Table 30-19 on page 1893). At the factory, the PIOSC is set to 16 MHz at room temperature, however, the frequency can be trimmed for other voltage or temperature conditions using software in the following ways:

- Default calibration: clear the UTEN bit and set the UPDATE bit in the **Precision Internal Oscillator Calibration (PIOSCCAL)** register.
- User-defined calibration: The user can program the UT value to adjust the PIOSC frequency. As the UT value increases, the generated period increases. To commit a new UT value, first set the UTEN bit, then program the UT field, and then set the UPDATE bit. The adjustment finishes within a few clock periods and is glitch free.
- Automatic calibration using the enable 32.768-kHz oscillator from the Hibernation module: Set the CAL bit in the **PIOSCCAL** register; the results of the calibration are shown in the RESULT field in the **Precision Internal Oscillator Statistic (PIOSCSTAT)** register. After calibration is complete, the PIOSC is trimmed using the trimmed value returned in the CT field.

#### 5.2.5.4 Main Oscillator (MOSC)

The main oscillator supports the use of crystals from 5 to 25 MHz. The system control's **RSCLKCFG** register can be configured to specify the MOSC as the system clock or as the PLL input source. The MOSC can be selected as the oscillator source by programming the OSCRC bit in the **RSCLKCFG** register. The NOXTAL bit in the **MOSCCTL** register allows the user to turn off power to the MOSC if no crystal is connected reducing power draw from the MOSC circuit.

##### **Main Oscillator Verification Circuit**

The clock control includes circuitry to ensure that the main oscillator is running at the appropriate frequency. The circuit monitors the main oscillator frequency and signals if the frequency is outside of the allowable band of attached crystals.

The detection circuit is enabled using the CVAL bit in the **Main Oscillator Control (MOSCCTL)** register. If this circuit is enabled and detects an error, and if the MOSCIM bit in the **MOSCCTL** register is clear, then the following sequence is performed by the hardware:

1. The MOSCFAIL bit in the **Reset Cause (RESC)** register is set.
2. The system clock is switched from the main oscillator to the PIOSC.
3. An internal system reset is initiated.
4. Reset is deasserted and the processor is directed to the NMI handler during the reset sequence.

#### 5.2.5.5 PLL

The PLL has two modes of operation: Normal and Power-Down

- Normal: The PLL oscillates based on the values in the **PLLREQ0** and **PLLREQ1** registers and drives the output.
- Power-Down: Most of the PLL internal circuitry is disabled and the PLL does not drive the output.

The modes are programmed using the PLLPWR bit in the **PLLREQ0** register (see page 298).

##### **PLL Configuration**

The PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the PLL to drive the output. The PLL is controlled using the **PLLREQ0**, **PLLREQ1** and **PLLSTAT** registers. Changes made to these registers do not become active until after the NEWFREQ bit in the **RSCLKCFG** register is enabled.

The clock source for the main PLL is selected by configuring the PLLSRC field in the **Run and Sleep Clock Configuration (RSCLKCFG)** register.

The PLL allows for the generation of system clock frequencies in excess of the reference clock provided. The reference clocks for the PLL are the PIOSC and the MOSC. The PLL is controlled by two registers, **PLLREQ0** and **PLLREQ1**. The PLL VCO frequency ( $f_{VCO}$ ) is determined through the following calculation:

$$f_{VCO} = f_{IN} * MDIV$$

where

$$f_{IN} = f_{XTAL} / (Q+1)(N+1) \text{ or } f_{PIOSC} / (Q+1)(N+1)$$

$$\text{MDIV} = \text{MINT} + (\text{MFRAC} / 1024)$$

The Q and N values are programmed in the **PLLREQ1** register. Note that to reduce jitter, MFRAC should be programmed to 0x0.

When the PLL is active, the system clock frequency (SysClk) is calculated using the following equation:

$$\text{SysClk} = f_{\text{VCO}} / (\text{PSYSDIV} + 1)$$

The PLL system divisor factor (PSYSDIV) determines the value of the system clock. Table 5-6 on page 244 shows how the system divisor encodings affect the system clock frequency when the  $f_{\text{VCO}} = 480$  MHz.

**Table 5-6. System Divisor Factors for  $f_{\text{VCO}}=480$  MHz**

| System Clock (SYSCLK) (MHz) | $f_{\text{VCO}}$ (MHz)= 480 MHz           |
|-----------------------------|-------------------------------------------|
|                             | System Divisors (PSYSDIV +1) <sup>a</sup> |
| 120                         | 4                                         |
| 60                          | 8                                         |
| 48                          | 10                                        |
| 30                          | 16                                        |
| 24                          | 20                                        |
| 12                          | 40                                        |
| 6                           | 80                                        |

a. The use of non-integer divisors introduce additional jitter which may affect interface performance.

If the main oscillator provides the clock reference to the PLL, the translation provided by hardware and used to program the PLL is available for software in the **PLL Frequency n (PLLREQn)** registers (see page 298). The internal translation provides a translation within  $\pm 1\%$  of the targeted PLL VCO frequency. Table 5-7 on page 244 shows the actual PLL frequency and error for a given crystal choice.

Table 5-7 on page 244 provides examples of the programming expected for the **PLLREQ0** and **PLLREQ1** registers. The first column specifies the input crystal frequency and the last column displays the PLL frequency given the values of MINT and N, when Q=0.

**Table 5-7. Actual PLL Frequency<sup>a</sup>**

| Crystal Frequency (MHz) | MINT (Decimal Value) | MINT (Hexadecimal Value) | N   | Reference Frequency (MHz) <sup>b</sup> | PLL Frequency (MHz) |
|-------------------------|----------------------|--------------------------|-----|----------------------------------------|---------------------|
| 5                       | 64                   | 0x40                     | 0x0 | 5                                      | 320                 |
| 6                       | 160                  | 0x35                     | 0x2 | 2                                      | 320                 |
| 8                       | 40                   | 0x28                     | 0x0 | 8                                      | 320                 |
| 10                      | 32                   | 0x20                     | 0x0 | 10                                     | 320                 |
| 12                      | 80                   | 0x50                     | 0x2 | 4                                      | 320                 |
| 16                      | 20                   | 0x14                     | 0x0 | 16                                     | 320                 |
| 18                      | 160                  | 0xA0                     | 0x8 | 2                                      | 320                 |
| 20                      | 16                   | 0x10                     | 0x0 | 20                                     | 320                 |
| 24                      | 40                   | 0x28                     | 0x2 | 8                                      | 320                 |

Table 5-7. Actual PLL Frequency (*continued*)

| Crystal Frequency (MHz) | MINT (Decimal Value) | MINT (Hexadecimal Value) | N   | Reference Frequency (MHz) <sup>b</sup> | PLL Frequency (MHz) |
|-------------------------|----------------------|--------------------------|-----|----------------------------------------|---------------------|
| 25                      | 64                   | 0x40                     | 0x4 | 5                                      | 320                 |
| 5                       | 96                   | 0x60                     | 0x0 | 5                                      | 480                 |
| 6                       | 80                   | 0x50                     | 0x0 | 6                                      | 480                 |
| 8                       | 60                   | 0x3C                     | 0x0 | 8                                      | 480                 |
| 10                      | 48                   | 0x30                     | 0x0 | 10                                     | 480                 |
| 12                      | 40                   | 0x28                     | 0x0 | 12                                     | 480                 |
| 16                      | 30                   | 0x1E                     | 0x0 | 16                                     | 480                 |
| 18                      | 80                   | 0x50                     | 0x2 | 6                                      | 480                 |
| 20                      | 24                   | 0x18                     | 0x0 | 20                                     | 480                 |
| 24                      | 20                   | 0x14                     | 0x0 | 24                                     | 480                 |
| 25                      | 96                   | 0x60                     | 0x4 | 5                                      | 480                 |

a. For all examples listed, Q=0

b. For a given crystal frequency, N should be chosen such that the reference frequency is within 4 to 30 MHz.

### PLL Operation

If a PLL configuration is changed, the PLL output frequency is unstable until it reconverges (relocks) to the new setting. The time between the configuration change and relock is  $T_{\text{READY}}$  (see Table 30-16 on page 1891). During the relock time, the affected PLL is not usable as a clock reference. Software can poll the LOCK bit in the **PLL Status (PLLSTAT)** register to determine when the PLL has locked.

Modification of the PLL VCO frequency may not be performed while the PLL serves as a clock source to the system. All changes to the PLL must be performed using a different clock source until the PLL has locked frequency. Thus, changing the PLL VCO frequency must be done as a sequence from PLL to PIOSC/MOSC and then PIOSC/MOSC to new PLL.

Hardware is provided to keep the PLL from being used as a system clock until the  $T_{\text{READY}}$  condition is met after one of the two changes above. It is the user's responsibility to have a stable clock source (like the main oscillator) before the **RSCLKCFG** register is re-programmed to enable the PLL. Software can use many methods to ensure that the system is clocked from the PLL, including periodically polling the PLLLRIS bit in the **Raw Interrupt Status (RIS)** register at offset 0x050, and enabling the PLL Lock interrupt in the **Interrupt Mask Control (IMC)** register at offset 0x054.

## 5.2.6 System Control

There are four levels of operation for the microcontroller defined as:

- Run mode
- Sleep mode
- Deep-Sleep mode
- Hibernation mode

For power-savings purposes, the peripheral-specific **RCGCx**, **SCGCx**, and **DCGCx** registers (for example, **RCGCWD**) control the clock-gating logic for that peripheral or block in the system while

the microcontroller is in Run, Sleep, and Deep-Sleep mode, respectively. These registers are located in the System Control register map starting at offsets 0x600, 0x700, and 0x800, respectively.

**Note:** A change in the **RCGCx** (or **SCGCx/DCGCx/PCx/SRx**) registers may not have an immediate effect on the clock in all situations. It is recommended that software poll the peripheral's **Peripheral Ready (PRx)** register to determine when a peripheral is ready to be accessed.

**Note:** If a peripheral is configured to be clock-gated during Run, Sleep- or Deep-Sleep mode, then software should ensure that there are no pending transfers or register accesses before or immediately after entering the clock-gated mode.

The following sections describe the different modes in detail.

### 5.2.6.1 Run Mode

In Run mode, the microcontroller actively executes code. Run mode provides normal operation of the processor and all of the peripherals that are currently enabled by the peripheral-specific **RCGC** registers. In run mode (and in sleep mode), the **Run and Sleep Clock Configuration (RSCLKCFG)** register specifies the source of SysClk. The source is either from the VCO output of the PLL divided down by a dedicated divisor (divisor value specified by the PSYSDIV field) or from the output of an oscillator divided down by a dedicated divisor (divisor value specified by the OSYSDIV field). The source is selected using the USEPLL bit in the **RSCLKCFG** register. The PLL has two sources of reference clock as an input: the main oscillator (MOSC) or the precision internal oscillator (PIOSC). The PLL input select is specified by PLLSRC. If the PLL VCO output is not selected as the source of SysClk then the following reference clocks can be programmed as an input:

- Main Oscillator (MOSC)
- Precision Internal Oscillator (PIOSC)
- Low-Frequency Internal Oscillator (LFIOSC)
- Hibernation Module Real-Time Oscillator Source (RTCOSC): The source of this signal can be either a 32.768-kHz oscillator source, an external 32.768-kHz clock source or the internal Hibernation Module Low-Frequency Oscillator (HIBLFIOSC). If this clock source is selected, it has to be enabled in the Hibernation Module as well.

The selection of these alternate sources is through the OSCSRC field in the **RSCLKCFG** register.

### 5.2.6.2 Sleep Mode

In Sleep mode, the clock frequency of the active peripherals is unchanged, but the processor and the memory subsystem are not clocked and therefore no longer execute code. Sleep mode is entered by the Cortex-M4F core executing a WFI (Wait for Interrupt) instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See “Power Management” on page 132 for more details.

Peripherals are clocked that are enabled in the peripheral-specific **SCGC** registers when auto-clock gating is enabled or the peripheral-specific **RCGC** registers when the auto-clock gating is disabled. The system clock has the same source and frequency as that during Run mode.

The option to use the PLL VCO or an alternate oscillator source such as MOSC, PIOSC, Hibernation Module real time clock, or the LFIOSC is the same as described in Run Mode. The **RSCLKCFG** register programming applies to Sleep Mode.

Additional sleep modes are available that lower the power consumption of the SRAM and Flash memory. However, the lower power consumption modes have slower sleep and wake-up times.

**Caution** – If the Cortex-M4F Debug Access Port (DAP) has been enabled, and the device wakes from a low power sleep or deep-sleep mode, the core may start executing code before all clocks to peripherals have been restored to their Run mode configuration. The DAP is usually enabled by software tools accessing the JTAG or SWD interface when debugging or flash programming. If this condition occurs, a Hard Fault is triggered when software accesses a peripheral with an invalid clock.

A software delay loop can be used at the beginning of the interrupt routine that is used to wake up a system from a WFI (Wait For Interrupt) instruction. This stalls the execution of any code that accesses a peripheral register that might cause a fault. This loop can be removed for production software as the DAP is most likely not enabled during normal execution.

Because the DAP is disabled by default (power on reset), the user can also power cycle the device. The DAP is not enabled unless it is enabled through the JTAG or SWD interface.

### 5.2.6.3 Deep-Sleep Mode

In Deep-Sleep mode, the clock frequency of the active peripherals may change (depending on the Deep-Sleep mode clock configuration) in addition to the processor clock being stopped. An interrupt returns the microcontroller to Run mode from one of the sleep modes; the sleep modes are entered on request from the code. Deep-Sleep mode is entered by first setting the SLEEPDEEP bit in the **System Control (SYSCTRL)** register (see page 179) and then executing a WFI instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See “Power Management” on page 132 for more details.

**Note:** If the Debug Access Port is enabled in Run Mode and attempts to transition into Deep-Sleep mode, the device is prevented from entering Deep-Sleep.

The Cortex-M4F processor core and the memory subsystem are not clocked in Deep-Sleep mode. Peripherals are clocked that are enabled in the peripheral-specific **DCGC** registers when auto-clock gating is enabled or the peripheral-specific **RCGC** registers when auto-clock gating is disabled. The system clock source is specified in the **DSCLKCFG** register. When the **DSCLKCFG** register is used, the internal oscillator source is powered up, if necessary, and other clocks are powered down. If the PLL is running at the time of the WFI instruction, hardware shuts down the PLL for power savings. For further power savings the PIOSC can be disabled through the PIOUSCPD bit in the **DSCLKCFG** register. When the Deep-Sleep exit event occurs, hardware brings the system clock back to the source and frequency it had at the onset of Deep-Sleep mode before enabling the clocks that had been stopped during the Deep-Sleep duration. If the PIOSC is used as the PLL reference clock source, it may continue to provide the clock during Deep-Sleep. See page 287.

**Note:** If the MOSC is chosen as the Deep-Sleep clock source in the **DSCLKCFG** register, the MOSC must also be configured as the Run and Sleep clock source in the **RSCLKCFG** register prior to entering Deep Sleep. If the PIOSC, LFIOSC, or Hibernation RTC Module Oscillator (HIBLFIOSC or 32-kHz crystal) is configured as the Run and Sleep clock source in the **RSCLKCFG** register, and the MOSC is configured as the Deep-Sleep clock source in the **DSCLKCFG** register, then two outcomes are possible:

- If the PIOSC is still powered in Deep Sleep (using the PIOUSCPD bit in the **DSCLKCFG** register) then the PIOSC is utilized as the clock source when entering Deep Sleep and the device enters and exits the Deep-Sleep state normally. The MOSC is not used as the clock source in Deep Sleep.
- If the PIOSC has been configured to be powered down in Deep Sleep, then the device can enter the Deep-Sleep state, but cannot exit properly. This situation can be avoided by programming the MOSC as the Run and Sleep clock source in the **RSCLKCFG** register prior to entering Deep Sleep.

To provide the lowest possible Deep-Sleep power consumption as well the ability to wake the processor from a peripheral without reconfiguring the peripheral for a change in clock, some of the communications modules have a Clock Control register at offset 0xFC8 in the module register space. The CS field in the Clock Control register allows the user to select the PIOSC or ALTCLK as the clock source for the module's baud clock. When the microcontroller enters Deep-Sleep mode, the PIOSC or ALTCLK becomes the source for the module clock as well, which allows the transmit and receive FIFOs to continue operation while the part is in Deep-Sleep. Figure 5-6 on page 248 shows how the clocks are selected.

**Figure 5-6. Module Clock Selection**

Additional power management modes are available that lower the power consumption of the peripheral memory, Flash, and SRAM memory. However, the lower power consumption modes have slower deep-sleep and wake-up times.

**Note:** If one or more wait states are configured for Run Mode, then when the device enters Deep-Sleep mode, it will achieve its lowest possible current. If there are no wait states applied in Run mode, then lowest possible current is not achieved.

#### 5.2.6.4 Dynamic Power Management

In addition to the Sleep and Deep-Sleep modes and the clock gating for the on-chip modules, there are several additional power mode options that allow the LDO, Flash memory, and SRAM into different levels of power savings while in Sleep or Deep-Sleep modes. In addition, software has the ability to control the LDO settings to gain a power advantage when running at slower speeds. Note that these features may not be available on all devices; the **System Properties (SYSPROP)** register provides information on whether a mode is supported on a given MCU. The following registers provide these capabilities:

- **Peripheral Power Control (PCx):** Controls power to peripheral if that peripheral has the ability to respond to a power request.

- **Peripheral Memory Power Control (xMPC):** Provides power control to some the peripheral memory arrays.
- **LDO Sleep Power Control (LDOSPCTL):** Controls the LDO value in Sleep mode
- **LDO Deep-Sleep Power Control (LDODPCTL):** Controls the LDO value in Deep-Sleep mode
- **LDO Sleep Power Calibration (LDOSPCAL):** Provides factory recommendations for the LDO value in Sleep mode
- **LDO Deep-Sleep Power Calibration (LDODPCAL):** Provides factory recommendations for the LDO value in Deep-Sleep mode
- **Sleep Power Configuration (SLPPWRCFG):** Controls the power saving modes for Flash memory and SRAM in Sleep mode
- **Deep-Sleep Power Configuration (DSLPPWRCFG):** Controls the power saving modes for Flash memory and SRAM in Deep-Sleep mode
- **Deep-Sleep Clock Configuration (DSCLKCFG):** Controls the clocking in Deep-Sleep mode
- **Sleep / Deep-Sleep Power Mode Status (SDPMST):** Provides status information on the various power saving events

### ***Peripheral Power Control***

The **Peripheral Power Control (PCx)** registers reside at offset 0x900 in the System Control module register space. For modules that reside in a separate power domain, the user has the capability to power down the module by setting the appropriate Pn bit to 0x0. This configuration provides the lowest power consumption state of the module. Currently the following registers can be programmed to disable power to the module:

- **PCCAN** register
- **PCEMAC** register
- **PCUSB** register
- **PCCCM** register

Modification to other PCx registers have no effect, since they are not on their own power domain.

### ***Peripheral Memory Power Control***

When Deep-Sleep is entered, users have the capability to reduce power further in peripheral modules which have their own associated memory array. Many of these peripherals can be programmed to enable a low-power retention mode or a power down of their associated peripheral SRAM array. If retention is supported and the PWRCTL bit field of the module's **xMPC** register is programmed to 0x1, the associated peripheral SRAM memory array is put in retention mode in which no accesses can be performed. When the PWRCTL bit is set to 0x0 in Deep-Sleep mode, the memory is powered off, the contents are lost and the SRAM is not accessible. The peripheral's **Power Domain Status (xPDS)** can be read to determine the status of the peripheral's memory array as well as the peripheral's current power domain status. The table below lists the capabilities of peripherals with SRAM arrays during low power modes.

**Table 5-8. Peripheral Memory Power Control**

| Module | Memory Retention Capability? | Memory Array Power Down Capability?                                  |
|--------|------------------------------|----------------------------------------------------------------------|
| USB    | Yes                          | Yes                                                                  |
| EMAC   | No                           | Yes<br>(only when power domain is off, <b>PCEMAC</b> register = 0x0) |
| CAN    | No                           | Yes                                                                  |

**LDO Power Control**

**Note:** While the device is connected through JTAG, the LDO control settings for Sleep or Deep-Sleep are not available and will not be applied.

Software can configure the **LDOSPCTL** register (see page 306) and/or the **LDODPCTL** register (see page 309) to dynamically raise or lower the LDO voltage in Sleep and Deep-Sleep mode depending on whether an increase in performance or reduction in power consumption is required. The VLDO field in the **LDOSPCTL** register is set to 1.2 V as default. The **LDODPCTL** register is set to an LDO voltage of 0.9 V as default. If an application requires performance over power consumption in Deep-Sleep, the Deep-Sleep LDO voltage can be configured to a higher voltage than 0.9 V during System Control initialization by setting the VADJEN bit and programming the VLDO field of the **LDODPCTL** register.

Before the LDO level is lowered in Sleep or Deep-Sleep, the system clock must be configured to an acceptable frequency in the **RSCLKCFG** register for Sleep mode and in **DSLPCLKCFG** for Deep-Sleep mode. The following table shows the maximum System Clock and PIOSC frequency with respect to the LDO voltage.

**Table 5-9. Maximum System Clock and PIOSC Frequency with Respect to LDO Voltage**

| Operating Voltage (LDO) | Maximum System Clock Frequency | PIOSC  |
|-------------------------|--------------------------------|--------|
| 1.2                     | 120 MHz                        | 16 MHz |
| 0.9                     | 30 MHz                         | 16 MHz |

The LDO Power Calibration registers, **LDOSPCAL** and **LDODPCAL**, provide suggested values for the LDO in the various modes. If software requests an LDO value that is too low or too high, the value is not accepted and an error is reported in the **SDPMST** register.

**Note:** When using the USB, Ethernet, EPI, and QSSI interfaces, the LDO must be configured to 1.2 V.

**Flash Memory and SRAM Power Control**

During Sleep or Deep-Sleep mode, Flash memory can be in either the default active mode or the low power mode; SRAM can be in the default active mode, standby mode, or low power mode. The active mode in each case provides the fastest times to sleep and wake up, but consumes more power. Low power mode provides the lowest power consumption, but takes longer to sleep and wake up.

The SRAM can be programmed to prohibit any power management by configuring the SRAMPM bit in the **Sleep Power Configuration (SLPPWRCFG)** register. This configuration operates in the same way that legacy Stellaris® devices operate and provides the fastest sleep and wake-up times, but consumes the most power while in Sleep and Deep-Sleep mode.

The following power saving options are available in Sleep and Deep-Sleep modes:

- The clocks can be gated according to the settings in the peripheral-specific **SCGC** or **DCGC** registers.
- In Deep-Sleep mode, the clock source can be changed and the PIOSC can be powered off (if no active peripheral requires it) using the **DSCLKCFG** register. These options are not available for Sleep mode.
- The LDO voltage can be changed using the **LDOSPCTL** or **LDODPCTL** register.
- The Flash memory can be put into low power mode.
- The SRAM can be put into standby or low power mode.

For typical power consumption and sleep/wake-up times, refer to “Current Consumption” on page 1937 and “Sleep Modes” on page 1899.

The **SDPMST** register provides results on the Dynamic Power Management command issued. It also has some real time status that can be viewed by a debugger or the core if it is running. These events do not trigger an interrupt and are meant to provide information to help tune software for power management. The status register gets written at the beginning of every Dynamic Power Management event request that provides error checking. There is no mechanism to clear the bits; they are overwritten on the next event. The data is real time and there is no event to register that information.

#### 5.2.6.5 Hibernation Mode

In this mode, the power supplies are turned off to the main part of the microcontroller and only the Hibernation module's circuitry is active. An external wake event or RTC event is required to bring the microcontroller back to Run mode. The Cortex-M4F processor and peripherals outside of the Hibernation module see a normal "power on" sequence and the processor starts running code. If the HIB module has been put in hibernation mode and a reset occurs, the reset handler should check the **HIB Raw Interrupt Status (HIBRIS)** register in the HIB module to determine the cause of the reset.

#### 5.2.6.6 Hardware System Service Request

The **Hardware System Service Request (HSSR)** register is used to issue a request that returns a device to factory settings. An HSSR consists of writing the appropriate key and data structure address offset to the **HSSR** register in the System Control Module. Any HSSR initiates a reset event as the first event in the process. Then the **HSSR** register is evaluated.

To write to the **HSSR** register the KEY field must be set to 0xCA. The CD0FF field in the **HSSR** register can have one of the following three values:

- 0x00.0000 – No request and/or the previous request completed successfully
- 0xFF.FFFF – No request and the previous request failed
- Anything else – The offset into SRAM of a HSSR request structure

During the HSSR routine, if anything else is seen in the CD0FF field, then the offset is examined for validity and the structure it points to is examined for validity. If either is invalid, the request has failed and 0xFF.FFFF is written to the CD0FF field.

The offset is valid if all the following conditions are met:

- The CD0FF value is word aligned (that is, the two LSBs are both zero)

- The CD0FF value is at least 0x2000.4000
- The CD0FF value is at most 0x2003.FFF0

Once a valid HSSR offset is determined, the following structure is examined in the SRAM that is indicated by the CD0FF field in the **HSSR** register. In order to initiate a return-to-factory settings function, the data structure must be as follows:

- Request (32 bits) = 0xFEED.0001
- Data 1 (32 bits) = 0x0201.0100
- Data 2 (32 bits) = 0x0D08.0503
- Data 3 (32 bits) = 0x5937.2215

If the data bytes are correct, then the device is returned to factory condition. During the return-to-factory settings function, the following events occur:

- The RAM is erased in the Hibernation module
- The system SRAM is erased
- The **FMPPEn** registers are set to 0xFFFF.FFFF (to allow a Flash erase operation to occur)
- The EEPROM pages are erased
- A mass-erase of the flash array occurs
- The **BOOTCFG** register is written with 0xFFFF.FFFE

Once the return-to-factory settings sequence is completed, the CD0FF field of the **HSSR** register is written with 0x00.0000, indicating a successful completion and activating a system reset.

## 5.3 Initialization and Configuration

The PLL is configured using direct register writes to the **PLLFREQn**, **MEMTIM0**, and **PLLSTAT** registers. The steps for initializing the system clock from POR to use the PLL from the main oscillator is as follows:

1. Once POR has completed, the PIOSC is acting as the system clock.
2. Power up the MOSC by clearing the NOXTAL bit in the **MOSCCTL** register.
3. If single-ended MOSC mode is required, the MOSC is ready to use. If crystal mode is required, clear the PWRDN bit and wait for the MOSCPUPRIS bit to be set in the **Raw Interrupt Status (RIS)**, indicating MOSC crystal mode is ready.
4. Set the OSCSRC field to 0x3 in the **RSCLKCFG** register at offset 0x0B0.
5. If the application also requires the MOSC to be the deep-sleep clock source, then program the DSOSCSRC field in the **DSCLKCFG** register to 0x3.
6. Write the **PLLFREQ0** and **PLLFREQ1** registers with the values of Q, N, MINT, and MFRAC to configure the desired VCO frequency setting.

7. Write the **MEMTIMO** register to correspond to the new system clock setting.
8. Wait for the **PLLSTAT** register to indicate the PLL has reached lock at the new operating point (or that a timeout period has passed and lock has failed, in which case an error condition exists and this sequence is abandoned and error processing is initiated).
9. Write the **RSCLKCFG** register's PSYSDIV value, set the USEPLL bit to enabled, and MEMTIMU bit.

If it is necessary to keep the MOSC powered on during automatic (deep-sleep) or accidental power down, then the MOSCDPD bit should be set to 0x1. Otherwise, if the MOSCDPD bit is set to 0x0, the MOSC is powered off when deep-sleep is entered or automatic power down occurs. The following table describes the relationship between the PWRDN bit in the **MOSCCTL** register and the MOSCDPD bit in the **DSCLKCFG** register:

**Table 5-10. MOSC Configurations**

| PWRDN bit | MOSCDPD field | Result                                                                                                                                                                                                                                |
|-----------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0         | 0             | MOSC is powered ON in run and sleep modes, but is disabled in accidental power down, when the PWRDN bit is set in the <b>MOSCCTL</b> register, or in deep-sleep mode only if it is not the deep-sleep clock source (DS0SCSRC != 0x3). |
| 0         | 1             | MOSC is powered and running in run, sleep and deep-sleep modes.                                                                                                                                                                       |
| 1         | 0             | MOSC is powered off, and does not run in any mode. Please note, that in this configuration, when the MOSC is disabled, the MOSC must not be chosen as a clock source or indeterminate results occur.                                  |
| 1         | 1             | MOSC runs and does not disable itself in run, sleep, and deep-sleep modes regardless of the fact that the PWRDN bit is set.                                                                                                           |

**Note:** The MOSCDPD bit has an effect in all modes of operation

To change the system clock frequency by changing its corresponding PSYSDIV or OSYSDIV value, a user must ensure timing parameters to memory are within range through the following steps:

1. If the change in system clock frequency changes the operational range of the timing parameters, the **MEMTIMO** register must be updated. If so, write the timing configuration register, **MEMTIMO**, setting the value to correspond to the final SYCLK frequency ( $f_{VCO}/\text{new SYSDIV}$  or  $f_{OSC}$ ). Otherwise the **MEMTIMO** register should not be changed.
2. Write the **RSCLKCFG** register's PSYSDIV value and MEMTIMU bit if the **MEMTIMO** register is updated in the first step. The new SYSDIV is now in effect.

## 5.4 Register Map

Table 5-11 on page 254 lists the System Control registers, grouped by function. The offset listed is a hexadecimal increment to the register's address, relative to the System Control base address of 0x400F.E000.

**Note:** Spaces in the System Control register space that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

Additional Flash and ROM registers defined in the System Control register space are described in the "Internal Memory" on page 600.

Table 5-11. System Control Register Map

| Offset                                                  | Name        | Type | Reset       | Description                                                  | See page |
|---------------------------------------------------------|-------------|------|-------------|--------------------------------------------------------------|----------|
| <b>System Control Registers (System Control Offset)</b> |             |      |             |                                                              |          |
| 0x000                                                   | DID0        | RO   | -           | Device Identification 0                                      | 261      |
| 0x004                                                   | DID1        | RO   | 0x1027.C06E | Device Identification 1                                      | 263      |
| 0x038                                                   | PTBOCTL     | RW   | 0x0000.0003 | Power-Temp Brown Out Control                                 | 265      |
| 0x050                                                   | RIS         | RO   | 0x0000.0000 | Raw Interrupt Status                                         | 267      |
| 0x054                                                   | IMC         | RW   | 0x0000.0000 | Interrupt Mask Control                                       | 269      |
| 0x058                                                   | MISC        | RW1C | 0x0000.0000 | Masked Interrupt Status and Clear                            | 271      |
| 0x05C                                                   | RESC        | RW   | 0x0000.0002 | Reset Cause                                                  | 273      |
| 0x060                                                   | PWRTC       | RW1C | 0x0000.0000 | Power-Temperature Cause                                      | 276      |

## 5.5 System Control Register Descriptions (System Control Offset)

All addresses given are relative to the System Control base address of 0x400F.E000.

**Register 1: Device Identification 0 (DID0), offset 0x000**

This register identifies the version of the microcontroller. Each microcontroller is uniquely identified by the combined values of the CLASS field in the **DID0** register and the PARTNO field in the **DID1** register. The MAJOR and MINOR bit fields indicate the die revision number. Combined, the MAJOR and MINOR bit fields indicate the part revision number.

| MAJOR Bitfield Value | MINOR Bitfield Value | Die Revision | Part Revision |
|----------------------|----------------------|--------------|---------------|
| 0x0                  | 0x0                  | A0           | 1             |
| 0x0                  | 0x1                  | A1           | 2             |
| 0x0                  | 0x2                  | A2           | 3             |

The major revision reflects changes to base layers of the design. The major revision number is indicated in the part number as a letter (A for first revision, B for second, and so on). This field is encoded as follows:</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>Revision A (initial device)</td></tr><tr><td>0x1</td><td>Revision B (first base layer revision)</td></tr><tr><td>0x2</td><td>Revision C (second base layer revision)</td></tr></table> <p>and so on.</p> | Value | Description | 0x0 | Revision A (initial device)                 | 0x1 | Revision B (first base layer revision) | 0x2 | Revision C (second base layer revision) |

## Register 2: Device Identification 1 (DID1), offset 0x004

This register identifies the device family, part number, temperature range, pin count, and package type. Each microcontroller is uniquely identified by the combined values of the CLASS field in the **DID0** register and the PARTNO field in the **DID1** register.

### Device Identification 1 (DID1)

Base 0x400F.E000

Offset 0x004

Type RO, reset 0x1027.C06E

**Register 3: Power-Temp Brown Out Control (PTBOCTL), offset 0x038**

This register determines, based on an individual event level, the appropriate next level of action (for example, NONE, System Control Interrupt, NMI, or reset) when an event occurs.

Power-temperature event actions are directed to the core as a System Control Interrupt or NMI. When a reset occurs, its behavior is controlled by the **Reset Behavior Control (RESBEHAVCTL)** register. If one of the events configured in the **PTBOCTL** register causes a reset, it is registered as a BOR interrupt in the **Reset Cause (RESC)** register.

**Note:**  $V_{DDA}$  is the supply voltage to the analog components of the device and  $V_{DD}$  is the supply voltage to the digital components of the device.

**Power-Temp Brown Out Control (PTBOCTL)**

Base 0x400F.E000

Offset 0x038

Type RW, reset 0x0000.0003

## Register 4: Raw Interrupt Status (RIS), offset 0x050

This register indicates the status for system control raw interrupts. An interrupt is sent to the interrupt controller if the corresponding bit in the **Interrupt Mask Control (IMC)** register is set. Writing a 1 to the corresponding bit in the **Masked Interrupt Status and Clear (MISC)** register clears an interrupt status bit.

### Raw Interrupt Status (RIS)

Base 0x400F.E000

Offset 0x050

Type RO, reset 0x0000.0000

## Register 5: Interrupt Mask Control (IMC), offset 0x054

This register contains the mask bits for system control raw interrupts. A raw interrupt, indicated by a bit being set in the **Raw Interrupt Status (RIS)** register, is sent to the interrupt controller if the corresponding bit in this register is set.

**Register 6: Masked Interrupt Status and Clear (MISC), offset 0x058**

On a read, this register gives the current masked status value of the corresponding interrupt in the **Raw Interrupt Status (RIS)** register. All of the bits are RW1C, thus writing a 1 to a bit clears the corresponding raw interrupt bit in the **RIS** register (see page 267).

## Register 7: Reset Cause (RESC), offset 0x05C

This register is set with the reset cause after reset. The bits in this register are sticky and maintain their state across multiple reset sequences. If a full POK-POR is initiated, the POR bit in the **RESC** register is set and all other bits are cleared. If the WDOGn, BOR or EXTRES configuration fields are set to 0x3 in the **RESBEHAVCTL** register and a simulated POR is initiated, the cause of the reset is reflected in the **RESC** register.

**Note:** After the **Reset Cause (RESC)** register is read, the **Hibernate Raw Interrupt Status (HIBRIS)** register in the Hibernation module must be evaluated to determine the full cause of the reset. Although an external reset assertion or POR resulting from a wake event is registered in the **RESC** register, the specific external wake source, including a low battery detect, is only registered in the **HIBRIS** register.

## Register 8: Power-Temperature Cause (PWRTC), offset 0x060

This register provides detailed information on the power subsystem event that caused a reset or interrupt. The event sets the condition in this register without regard to whether it is used to generate a System control Interrupt, Reset, NMI, or no action. The **PTBOCTL** register contains the action to be taken on the specific events. The combination of the **PWRTC** register outputs and the **PTBOCTL** register causes the appropriate interrupt or reset condition to occur and the corresponding status bits to be set.

## Register 9: NMI Cause Register (NMIC), offset 0x064

This register provides the detailed information on the cause of an NMI interrupt. These bits are set via hardware when the event occurs AND the higher level control indicates that it should be NMI event.

**Note:** The **NMIC** register has to be cleared by the following sequence:

1. Read the **NMIC** register to identify the source of the NMI.
2. Clear the source of the NMI.
3. Read the **NMIC** register again to check the status.
4. Write a 0 into the **NMIC** register bit that corresponds with the NMI source.
5. Read the **NMIC** to check whether it is cleared. If not, repeat 3 on page 277 and 4 on page 277 again.

**Register 10: Main Oscillator Control (MOSCCTL), offset 0x07C**

This register provides control over the features of the main oscillator, including the ability to enable the MOSC clock verification circuit, what action to take when the MOSC fails, and whether or not a crystal is connected. When enabled, this circuit monitors the frequency of the MOSC to verify that the oscillator is operating within specified limits. If the clock goes invalid after being enabled, the microcontroller issues a power-on reset and reboots to the NMI handler or generates an interrupt.

**Main Oscillator Control (MOSCCTL)**

## Register 11: Run and Sleep Mode Configuration Register (RSCLKCFG), offset 0x0B0

**Important:** When transitioning the system clock configuration to use the MOSC as the fundamental clock source, the PWRDN bit must be set in the **MOSCCTL** register prior to reselecting the MOSC for proper operation.

### Run and Sleep Mode Configuration Register (RSCLKCFG)

Base 0x400F.E000  
Offset 0x0B0

The <b>SCGCn</b> and <b>DCGCn</b> registers allow unused peripherals to consume less power when the microcontroller is in a sleep mode. |
| Value     | Description                                                                                                                                                                                                                                                                                                                                                                                                        |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |       |             |   |                                                                                                                   |   |                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 0         | The <b>Run-Mode Clock Gating Control (RCGCn)</b> registers are used when the microcontroller enters a sleep mode.                                                                                                                                                                                                                                                                                                  |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |       |             |   |                                                                                                                   |   |                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 1         | If the microcontroller is in sleep mode, the <b>SCGCn</b> registers are used to control the clocks distributed to the peripherals. If the microcontroller is in deep-sleep mode, the <b>DCGCn</b> registers are used to control the clocks distributed to the peripherals. The <b>SCGCn</b> and <b>DCGCn</b> registers allow unused peripherals to consume less power when the microcontroller is in a sleep mode. |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |       |             |   |                                                                                                                   |   |                                                                                                                                                                                                                                                                                                                                                                                                                    |

The **RCGCn** registers are always used to control the clocks in Run mode.

## Register 12: Memory Timing Parameter Register 0 for Main Flash and EEPROM (MEMTIM0), offset 0x0C0

The **MEMTIM0** register provides timing parameters for the main Flash and EEPROM memories. The timing parameters apply to the memory while the system is in run or sleep mode; the clocking for these modes is consistent and unchanged since the system clock frequency and source remains unchanged during transitions between run-to-sleep and sleep-back-to-run. Writes to **MEMTIM0** do not have any effect on system state; the register contents are applied only when the MEMTIMU bit in the **RSCLKCFG** register is set. Doing so allows the software to execute out of the same memory system for which the timing parameters are being modified.

Depending on the CPU frequency, the application must program specific values into the fields of the **Memory Timing Parameter Register 0 for Main Flash and EEPROM (MEMTIM0)**. The following table details the bit field values that are required for the given CPU frequency ranges.

**Table 5-12. MEMTIM0 Register Configuration versus Frequency**

| CPU Frequency range (f) in MHz | Time Period Range (t) in ns | FBCHT/EBCHT | FBCE/EBCE | FWS/EWS |
|--------------------------------|-----------------------------|-------------|-----------|---------|
| 16                             | 62.5                        | 0x0         | 1         | 0x0     |
| 16 < f ≤ 40                    | 62.5 > t ≥ 25               | 0x2         | 0         | 0x1     |
| 40 < f ≤ 60                    | 25 > t ≥ 16.67              | 0x3         | 0         | 0x2     |
| 60 < f ≤ 80                    | 16.67 > t ≥ 12.5            | 0x4         | 0         | 0x3     |
| 80 < f ≤ 100                   | 12.5 > t ≥ 10               | 0x5         | 0         | 0x4     |
| 100 < f ≤ 120                  | 10 > t ≥ 8.33               | 0x6         | 0         | 0x5     |

**Note:** The associated Flash and EEPROM fields in the **MEMTIM0** register must be programmed to the same values. For example, the FWS field must be programmed to the same value as the EWS field.

Refer to “Flash Memory” on page 604 and “EEPROM” on page 615 for more information about Flash and EEPROM programming.

## Register 13: Alternate Clock Configuration (ALTCLKCFG), offset 0x138

The **ALTCLKCFG** register specifies the alternate clock source used by many of the peripherals.

### Alternate Clock Configuration (ALTCLKCFG)

Base 0x400F.E000

Offset 0x138

Type RW, reset 0x0000.0000

## Register 14: Deep Sleep Clock Configuration Register (DSCLKCFG), offset 0x144

The **DSCLKCFG** register specifies the behavior of the clock system while in deep sleep.

Note that the MOSCDPD bit not only affects deep-sleep mode, but all other modes as well depending on the value of the bit. Please refer to the following table when programming this bit:

**Table 5-13. MOSC Configurations**

| PWRDN bit | MOSCDPD field | Result                                                                                                                                                                                                                               |
|-----------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0         | 0             | MOSC is powered ON in run and sleep modes, but is disabled in accidental power down, when the PWRDN bit is set in the <b>MOSCCTL</b> register, or in deep-sleep mode only if it is not the deep-sleep clock source (DS0SCSRC !=0x3). |
| 0         | 1             | MOSC is powered and running in run, sleep and deep-sleep modes.                                                                                                                                                                      |
| 1         | 0             | MOSC is powered off, and does not run in any mode. Please note, that in this configuration, when the MOSC is disabled, the MOSC must not be chosen as a clock source or indeterminate results occur.                                 |
| 1         | 1             | MOSC runs and does not disable itself in run, sleep, and deep-sleep modes regardless of the fact that the PWRDN bit is set.                                                                                                          |

**Note:** The MOSCDPD bit has an effect in all modes of operation

**Note:** If the MOSC is chosen as the Deep-Sleep clock source in the **DSCLKCFG** register, the MOSC must also be configured as the Run and Sleep clock source in the **RSCLKCFG** register prior to entering Deep Sleep. If the PIOSC, LFIOSC, or Hibernation RTC Module Oscillator (HIBLFIOSC or 32-kHz crystal) is configured as the Run and Sleep clock source in the **RSCLKCFG** register, and the MOSC is configured as the Deep-Sleep clock source in the **DSCLKCFG** register, then two outcomes are possible:

- If the PIOSC is still powered in Deep Sleep (using the PIOSCPD bit in the **DSCLKCFG** register) then the PIOSC is utilized as the clock source when entering Deep Sleep and the device enters and exits the Deep-Sleep state normally. The MOSC is not used as the clock source in Deep Sleep.
- If the PIOSC has been configured to be powered down in Deep Sleep, then the device can enter the Deep-Sleep state, but cannot exit properly. This situation can be avoided by programming the MOSC as the Run and Sleep clock source in the **RSCLKCFG** register prior to entering Deep Sleep.

| 9:0       | DSSYSDIV | RW   | 0x0   | <p>Deep Sleep Clock Divisor</p> <p>This field specifies the system clock divisor value during deep sleep mode. The clock source selected by DS0SCSRC is divided by DSSYSDIV + 1:</p> $f_{\text{SYSCLK}} = f_{\text{OSCCLK}} / (\text{DSSYSDIV} + 1)$ <p><b>Note:</b> Values 0x0 and 0x1 should not be used. If Deep-Sleep clock divide by 1 or divide by 2 is desired, the 0SYSDIV bit field of the <b>RSCLKCFG</b> register must be configured for the desired Deep-Sleep divider before entering Deep-Sleep. In this case, the Q post-divider bit field in the <b>PLLREQ1</b> register may need to be adjusted to keep the system clock frequency within the maximum clock frequency before entering Deep-Sleep.</p> |

## Register 15: Divisor and Source Clock Configuration (DIVSCLK), offset 0x148

The **DIVSCLK** register specifies the source and divisor of the DIVSCLK reference clock output. This signal can be used as a clock source to an external device but bears no timing relationship to other signals.

**Note:** The DIVSCLK signal output is not synchronized to the System Clock.

### Divisor and Source Clock Configuration (DIVSCLK)

Base 0x400F.E000

Offset 0x148

Type RW, reset 0x0000.0000

## Register 16: System Properties (SYSPROP), offset 0x14C

This register provides information on whether certain System Control properties are present on the microcontroller.

### System Properties (SYSPROP)

Base 0x400F.E000

Offset 0x14C

Type RO, reset 0x0003.1F31

**Register 17: Precision Internal Oscillator Calibration (PIOSCCAL), offset 0x150**

This register provides the ability to update or recalibrate the precision internal oscillator. Note that a 32.768-kHz oscillator must be used as the Hibernation module clock source for the user to be able to calibrate the PIOSC.

**Precision Internal Oscillator Calibration (PIOSCCAL)**

Base 0x400F.E000

Offset 0x150

Type RW, reset 0x0000.0000

## Register 19: PLL Frequency 0 (PLLREQ0), offset 0x160

This register always contains the variables used to configure the PLL. If the PLL is reprogrammed, it must go through a relock sequence which is defined by the parameter  $T_{\text{READY}}$  in Table 30-16 on page 1891. When controlling this register directly, software must change this value while the PLL is powered down. Writes to **PLLREQ0** are delayed from affecting the PLL until the **RSCLKCFG** register **NEWREQ** bit is written with a 1.

The PLL frequency can be calculated using the following equation:

$$f_{\text{VCO}} = (f_{\text{IN}} * \text{MDIV})$$

where

$$f_{\text{IN}} = f_{\text{XTAL}} / ((Q+1)(N+1)) \text{ or } f_{\text{PIOSC}} / ((Q+1)(N+1))$$

$$\text{MDIV} = \text{MINT} + (\text{MFRAC} / 1024)$$

The Q and N values are programmed in the **PLLREQ1** register. Note that to reduce jitter, MFRAC should be programmed to 0x0.

**Register 20: PLL Frequency 1 (PLLREQ1), offset 0x164**

This register always contains the current Q and N values presented to the system PLL. If the PLL is reconfigured, it must go through a relock sequence which takes about 128 PIOSC clocks. When controlling this register directly, software must change this value while the PLL is powered down. Writes to **PLLREQ0** are delayed from affecting the PLL until the **RSCLKCFG** register NEWFREQ bit is written with a 1.

The MINT and MFRAC fields are present in the **PLLREQ0** register.

## Register 25: LDO Sleep Power Control (LDOSPCTL), offset 0x1B4

This register specifies the LDO output voltage in Sleep mode. This register should be configured while in Run Mode. If the VADJEN bit is set, writes can be made to the VLDO field within the provided encodings. The following table shows the maximum clock frequencies with respect to LDO Voltage.

**Table 5-14. Maximum System Clock and PIOSC Frequency with Respect to LDO Voltage**

| Operating Voltage (LDO) | Maximum System Clock Frequency | PIOSC  |
|-------------------------|--------------------------------|--------|
| 1.2                     | 120 MHz                        | 16 MHz |
| 0.9                     | 30 MHz                         | 16 MHz |

## Register 26: LDO Sleep Power Calibration (LDOSPCAL), offset 0x1B8

This register provides factory determined values that are recommended for the VLDO field in the **LDOSPCTL** register while in Sleep mode. The reset value of this register cannot be determined until the product has been characterized.

### LDO Sleep Power Calibration (LDOSPCAL)

Base 0x400F.E000

Offset 0x1B8

Type RO, reset 0x0000.1818

| 31:16     | reserved | RO   | 0x0   | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                              |
| 15:8      | WITHPLL  | RO   | 0x18  | Sleep with PLL<br>The value in this field is the suggested value for the VLDO field in the <b>LDOSPCTL</b> register when using the PLL. This value provides the lowest recommended LDO output voltage for use with the PLL at the maximum specified value. |
| 7:0       | NOPLL    | RO   | 0x18  | Sleep without PLL<br>The value in this field is the suggested value for the VLDO field in the <b>LDOSPCTL</b> register when not using the PLL. This value provides the lowest recommended LDO output voltage for use without the PLL.                      |

**Register 27: LDO Deep-Sleep Power Control (LDODPCTL), offset 0x1BC**

This register specifies the LDO output voltage in Sleep mode. This register should be configured while in Run Mode. If the VADJEN bit is set, writes can be made to the VLDO field within the provided encodings. The following table shows the maximum clock frequencies with respect to LDO Voltage.

**Table 5-15. Maximum System Clock and PIOSC Frequency with Respect to LDO Voltage**

| Operating Voltage (LDO) | Maximum System Clock Frequency | PIOSC  |
|-------------------------|--------------------------------|--------|
| 1.2                     | 120 MHz                        | 16 MHz |
| 0.9                     | 30 MHz                         | 16 MHz |

**LDO Deep-Sleep Power Control (LDODPCTL)**

Base 0x400F.E000

Offset 0x1BC

Type RW, reset 0x0000.0012

**Register 28: LDO Deep-Sleep Power Calibration (LDODPCAL), offset 0x1C0**

This register provides factory determined values that are recommended for the VLDO field in the **LDODPCTL** register while in Deep-Sleep mode. The reset value of this register cannot be determined until the product has been characterized.

This value provides the lowest recommended LDO output voltage for use with the low-frequency internal oscillator. |

## Register 29: Sleep / Deep-Sleep Power Mode Status (SDPMST), offset 0x1CC

This register provides status information on the Sleep and Deep-Sleep power modes as well as some real time status that can be viewed by a debugger or the core if it is running. These events do not trigger an interrupt and are meant to provide information that can help tune software for power management. The status register gets written at the beginning of every Dynamic Power Management event request with the results of any error checking. There is no mechanism to clear the bits; they are overwritten on the next event. The LDOUA, FLASHLP, LOWPWR, PRACT bits provide real time data and there are no events to register that information.

**Register 30: Reset Behavior Control Register (RESBEHAVCTL), offset 0x1D8**

The Reset Behavior Control Register contains system management controls.

The **RESBEHAVCTL** register effect occurs immediately when the register is changed. The next power-on reset sequence returns the reset value.

If any bit field below is set to 0x3 when a reset occurs, a simulated POR will be generated and the appropriate reset cause will be set in the **Reset Cause (RESC)** register. During a simulated POR, registers are reloaded and the bootloader is executed. If a full POR is initiated the POR bit in the **RESC** register will be set and all other bits will be cleared.

**Reset Behavior Control Register (RESBEHAVCTL)**

Base 0x400F.E000

Offset 0x1D8

Type RW, reset 0xFFFF.FFFF

**Register 31: Hardware System Service Request (HSSR), offset 0x1F4**

The **HSSR** register is used to control system configuration functions, such as Return-to-Factory settings. A write to the **HSSR** register stores a command descriptor pointer (CDOFF) value if the **KEY** field is correct (0xCA). A successful write to this register also initiates a system reset. The initialization process executes before examining the **HSSR** register and processing the command. This register can only be accessed in privilege mode. Refer to “Hardware System Service Request” on page 251 for more information on how to use the **HSSR** register.

## Register 32: USB Power Domain Status (USBPDS), offset 0x280

This register provides the status of power to the USB SRAM memory array.

**Note:** If the **USBMPC** register's **PWRCTL** field is set to 0x3 and the power domain to the USB is turned off by writing a 0 to the **P0** bit of the **PCUSB** register, then the SRAM memory goes into retention and the **MEMSTAT** field of the **USBPDS** register reads as 0x1 (retention).

**Register 33: USB Memory Power Control (USBMPC), offset 0x284**

This register provides power control to the peripheral memory array.

**Note:** If the **USBMPC** register's PWRCTL field is set to 0x3 and the power domain to the USB is turned off by writing a 0 to the P0 bit of the **PCUSB** register, then the SRAM memory goes into retention and the MEMSTAT field of the **USBPDS** register reads as 0x1 (retention).

**Register 34: Ethernet MAC Power Domain Status (EMACPDS), offset 0x288**

This register provides the status of power to the EMAC SRAM memory array.

**Note:** The EMAC memory array does not support retention and can only be turned ON and OFF. Memory array OFF is supported only when the power domain is off. If the memory array is currently turned on (PWRCTL = 0x3) and the power control to the EMAC is subsequently removed by clearing the P0 bit of the **PCEMAC** register, the event causes the memory array to turn off and the MEMSTAT bit in the **EMACPDS** register to be 0x0 (array OFF).

**Ethernet MAC Power Domain Status (EMACPDS)**

**Register 35: Ethernet MAC Memory Power Control (EMACMPC), offset 0x28C**

This register provides power control to the peripheral memory array.

**Note:** The EMAC memory array does not support retention and can only be turned ON and OFF. Memory array OFF is supported only when the power domain is off. If the memory array is turned on (PWRCTL = 0x3) and the power control to the EMAC is removed by clearing the P0 bit of the **PCEMAC** register, the memory array is turned off and the MEMSTAT bit in the **EMACPDS** register is 0x0.

**Ethernet MAC Memory Power Control (EMACMPC)**

**Register 36: CAN 0 Power Domain Status (CAN0PDS), offset 0x298**

This register provides the status of power to the CAN0 SRAM memory array.

**Note:** The CAN0 memory array does not support retention and can only be turned ON and OFF. If the memory array is currently turned on (PWRCTL = 0x3) and the power control to the CAN0 is subsequently removed by clearing the P0 bit of the **PCCAN** register, the event causes the memory array to turn off and the MEMSTAT bit in the **CAN0PDS** register to be 0x0 (array OFF).

**Register 38: CAN 1 Power Domain Status (CAN1PDS), offset 0x2A0**

This register provides the status of power to the CAN 1 SRAM memory array.

**Note:** The CAN1 memory array does not support retention and can only be turned ON and OFF. If the memory array is currently turned on (PWRCTL = 0x3) and the power control to CAN1 is subsequently removed by clearing the P1 bit of the **PCCAN** register, the event causes the memory array to turn off and the MEMSTAT bit in the **CAN1PDS** register to be 0x0 (array OFF).

**CAN 1 Power Domain Status (CAN1PDS)**

## Register 40: Watchdog Timer Peripheral Present (PPWD), offset 0x300

The **PPWD** register provides software information regarding the watchdog modules.

**Important:** This register should be used to determine which watchdog timers are implemented on this microcontroller.

## Register 43: Micro Direct Memory Access Peripheral Present (PPDMA), offset 0x30C

The **PPDMA** register provides software information regarding the  $\mu$ DMA module.

**Important:** This register should be used to determine if the  $\mu$ DMA module is implemented on this microcontroller.

## Register 47: Synchronous Serial Interface Peripheral Present (PPSSI), offset 0x31C

The **PPSSI** register provides software information regarding the SSI modules.

**Important:** This register should be used to determine which SSI modules are implemented on this microcontroller. However, to support legacy software, the **DC2** register is available. A read of the **DC2** register correctly identifies if a legacy SSI module is present. Software must use this register to determine if a module that is not supported by the **DC2** register is present.

**Register 53: Analog Comparator Peripheral Present (PPACMP), offset 0x33C**

The **PPACMP** register provides software information regarding the analog comparator module.

**Important:** This register should be used to determine if the analog comparator module is implemented on this microcontroller.

Note that the **Analog Comparator Peripheral Properties (ACMPPP)** register indicates how many analog comparator blocks are included in the module.

## Register 68: Watchdog Timer Software Reset (SRWD), offset 0x500

The **SRWD** register provides software the capability to reset the available watchdog modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRWD** register. While the **SRWD** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRWD** bit.

There may be latency from the clearing of the **SRWD** bit to when the peripheral is ready for use. Software should check the corresponding **PRWD** bit to verify that the Watchdog Timer Module registers are ready to be accessed.

**Important:** This register should be used to reset the watchdog modules.

## Register 69: 16/32-Bit General-Purpose Timer Software Reset (SRTIMER), offset 0x504

The **SRTIMER** register provides software the capability to reset the available 16/32-bit timer modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRTIMER** register. While the **SRTIMER** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRTIMER** bit.

There may be latency from the clearing of the **SRTIMER** bit to when the peripheral is ready for use. Software should check the corresponding **PRTIMER** bit to verify that the Timer Module registers are ready to be accessed.

**Important:** This register should be used to reset the timer modules.

## Register 70: General-Purpose Input/Output Software Reset (SRGPIO), offset 0x508

The **SRGPIO** register provides software the capability to reset the available GPIO modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRGPIO** register. While the **SRGPIO** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRGPIO** bit.

There may be latency from the clearing of the **SRGPIO** bit to when the peripheral is ready for use. Software should check the corresponding **PRGPIO** bit to verify that the GPIO Module registers are ready to be accessed.

**Important:** This register should be used to reset the GPIO modules.

## Register 71: Micro Direct Memory Access Software Reset (SRDMA), offset 0x50C

The **SRDMA** register provides software the capability to reset the available  $\mu$ DMA module.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRDMA** register. While the **SRDMA** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRDMA** bit.

There may be latency from the clearing of the **SRDMA** bit to when the peripheral is ready for use. Software should check the corresponding **PRDMA** bit to verify that the  $\mu$ DMA Module registers are ready to be accessed.

**Important:** This register should be used to reset the  $\mu$ DMA module.

**Register 72: EPI Software Reset (SREPI), offset 0x510**

The **SREPI** register provides software the capability to reset the available EPI module.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SREPI** register. While the **SREPI** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SREPI** bit.

There may be latency from the clearing of the **SREPI** bit to when the peripheral is ready for use. Software should check the corresponding **PREPI** bit to verify that the EPI Module registers are ready to be accessed.

**Important:** This register should be used to reset the EPI module.

## Register 74: Universal Asynchronous Receiver/Transmitter Software Reset (SRUART), offset 0x518

The **SRUART** register provides software the capability to reset the available UART modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRUART** register. While the **SRUART** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRUART** bit.

There may be latency from the clearing of the **SRUART** bit to when the peripheral is ready for use. Software should check the corresponding **PRUART** bit to verify that the UART Module registers are ready to be accessed.

**Important:** This register should be used to reset the UART modules.

## Register 75: Synchronous Serial Interface Software Reset (SRSSI), offset 0x51C

The **SRSSI** register provides software the capability to reset the available SSI modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRSSI** register. While the **SRSSI** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRSSI** bit.

There may be latency from the clearing of the **SRSSI** bit to when the peripheral is ready for use. Software should check the corresponding **PRSSI** bit to verify that the SSI Module registers are ready to be accessed.

**Important:** This register should be used to reset the SSI modules.

**Register 79: Analog-to-Digital Converter Software Reset (SRADC), offset 0x538**

The **SRADC** register provides software the capability to reset the available ADC modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRADC** register. While the **SRADC** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRADC** bit.

There may be latency from the clearing of the **SRADC** bit to when the peripheral is ready for use. Software should check the corresponding **PRADC** bit to verify that the ADC Module registers are ready to be accessed.

**Important:** This register should be used to reset the ADC modules.

## Register 80: Analog Comparator Software Reset (SRACMP), offset 0x53C

The **SRACMP** register provides software the capability to reset the available analog comparator module.

A block is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRACMP** register. While the **SRACMP** bit is 1, the module is held in reset.
2. Software completes the reset process by clearing the **SRACMP** bit.

There may be latency from the clearing of the **SRACMP** bit to when the module is ready for use. Software should check the corresponding **PRACMP** bit to verify that the Analog Comparator Module registers are ready to be accessed.

**Important:** This register should be used to reset the analog comparator module.

## Register 82: Quadrature Encoder Interface Software Reset (SRQEI), offset 0x544

The **SRQEI** register provides software the capability to reset the available QEI modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRQEI** register. While the **SRQEI** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRQEI** bit.

There may be latency from the clearing of the **SRQEI** bit to when the peripheral is ready for use. Software should check the corresponding **PRQEI** bit to verify that the QEI Module registers are ready to be accessed.

**Important:** This register should be used to reset the QEI modules.

## Register 84: CRC and Cryptographic Modules Software Reset (SRCCM), offset 0x574

The **SRCCM** register provides software the capability to reset the CRC and Cryptographic Modules (AES, DES, and SHA/MD5).

A module is reset by software using a simple two-step process:

1. Software sets the bit in the **SRCCM** register. While the **SRCCM** bit is 1, the peripherals are held in reset.
2. Software completes the reset process by clearing the **SRCCM** bit.

There may be latency from the clearing of the **SRCCM** bit to when the peripheral is ready for use. Software should check the corresponding **PRCCM** bit to verify that the CRC and Cryptographic Module (AES, DES, and SHA/MD5) registers are ready to be accessed.

**Important:** This register should be used to reset the CRC, AES, DES, and SHA/MD5 modules.

## Register 86: Watchdog Timer Run Mode Clock Gating Control (RCGCWD), offset 0x600

The **RCGCWD** register provides software the capability to enable and disable watchdog modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

**Important:** This register should be used to control the clocking for the watchdog modules

## Register 87: 16/32-Bit General-Purpose Timer Run Mode Clock Gating Control (RCGCTIMER), offset 0x604

The **RCGCGPT32** register provides software the capability to enable and disable 16/32-bit timer modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

**Important:** This register should be used to control the clocking for the timer modules.

## Register 88: General-Purpose Input/Output Run Mode Clock Gating Control (RCGCGPIO), offset 0x608

The **RCGCGPIO** register provides software the capability to enable and disable GPIO modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

**Important:** This register should be used to control the clocking for the GPIO modules.

Register 89: Micro Direct Memory Access Run Mode Clock Gating Control (RCGCDMA), offset 0x60C

The **RCGCDMA** register provides software the capability to enable and disable the  $\mu$ DMA module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

**Important:** This register should be used to control the clocking for the  $\mu$ DMA module.

## Register 93: Synchronous Serial Interface Run Mode Clock Gating Control (RCGCSSI), offset 0x61C

The **RCGCSSI** register provides software the capability to enable and disable the SSI modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

**Important:** This register should be used to control the clocking for the SSI modules.

## Register 95: Universal Serial Bus Run Mode Clock Gating Control (RCGCUSB), offset 0x628

The **RCGCUSB** register provides software the capability to enable and disable the USB module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

**Important:** This register should be used to control the clocking for the USB module.

## Register 98: Analog Comparator Run Mode Clock Gating Control (RCGCACMP), offset 0x63C

The **RCGCACMP** register provides software the capability to enable and disable the analog comparator module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

**Important:** This register should be used to control the clocking for the analog comparator module.

## Register 101: EEPROM Run Mode Clock Gating Control (RCGCEEPROM), offset 0x658

The **RCGCEEPROM** register provides software the capability to enable and disable the EEPROM module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

## Register 102: CRC and Cryptographic Modules Run Mode Clock Gating Control (RCGCCCM), offset 0x674

The **RCGCCCM** register provides software the capability to enable and disable the CRC and Encryption Modules (AES, DES, and SHA/MD5) in Run mode. When enabled, the modules are provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

**Important:** This register should be used to control the clocking for the CRC, AES, DES, and SHA/MD5 modules.

## Register 105: 16/32-Bit General-Purpose Timer Sleep Mode Clock Gating Control (SCGCTIMER), offset 0x704

The **SCGCGPT32** register provides software the capability to enable and disable 16/32-bit timer modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the timer modules.

## Register 107: Micro Direct Memory Access Sleep Mode Clock Gating Control (SCGCDMA), offset 0x70C

The **SCGCDMA** register provides software the capability to enable and disable the  $\mu$ DMA module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the  $\mu$ DMA module.

## Register 112: Inter-Integrated Circuit Sleep Mode Clock Gating Control (SCGCI2C), offset 0x720

The **SCGCI2C** register provides software the capability to enable and disable the I<sup>2</sup>C modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the I<sup>2</sup>C modules.

## Register 115: Analog-to-Digital Converter Sleep Mode Clock Gating Control (SCGCADC), offset 0x738

The **SCGCADC** register provides software the capability to enable and disable the ADC modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the ADC modules.

## Register 117: Pulse Width Modulator Sleep Mode Clock Gating Control (SCGCPWM), offset 0x740

The **SCGCPWM** register provides software the capability to enable and disable the PWM modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the PWM modules.

## Register 121: Ethernet MAC Sleep Mode Clock Gating Control (SCGCEMAC), offset 0x79C

The **SCGCEMAC** register provides software the capability to enable and disable the Ethernet MAC module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the Ethernet MAC module.

## Register 124: General-Purpose Input/Output Deep-Sleep Mode Clock Gating Control (DCGCGPIO), offset 0x808

The **DCGCGPIO** register provides software the capability to enable and disable GPIO modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the GPIO modules.

### General-Purpose Input/Output Deep-Sleep Mode Clock Gating Control (DCGCGPIO)

Base 0x400F.E000

Offset 0x808

## Register 125: Micro Direct Memory Access Deep-Sleep Mode Clock Gating Control (DCGCDMA), offset 0x80C

The **DCGCDMA** register provides software the capability to enable and disable the  $\mu$ DMA module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the  $\mu$ DMA module.

## Register 129: Synchronous Serial Interface Deep-Sleep Mode Clock Gating Control (DCGCSSI), offset 0x81C

The **DCGCSSI** register provides software the capability to enable and disable the SSI modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the SSI modules.

### Synchronous Serial Interface Deep-Sleep Mode Clock Gating Control (DCGCSSI)

Base 0x400F.E000

Offset 0x81C

## Register 130: Inter-Integrated Circuit Deep-Sleep Mode Clock Gating Control (DCGCI2C), offset 0x820

The **DCGCI2C** register provides software the capability to enable and disable the I<sup>2</sup>C modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the I<sup>2</sup>C modules.

## Register 133: Analog-to-Digital Converter Deep-Sleep Mode Clock Gating Control (DCGCADC), offset 0x838

The **DCGCADC** register provides software the capability to enable and disable the ADC modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the ADC modules.

## Register 138: CRC and Cryptographic Modules Deep-Sleep Mode Clock Gating Control (DCGCCCM), offset 0x874

The **DCGCCCM** register provides software the capability to enable and disable the CRC, AES, DES, and SHA/MD5 modules in deep-sleep mode. When enabled, the modules are provided a clock. When disabled, the clock is disabled to save power.

**Important:** This register should be used to control the clocking for the CRC, AES, DES, and SHA/MD modules.

**Register 140: Watchdog Timer Power Control (PCWD), offset 0x900**

**Important:** The Watchdog Timer modules do not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCWD** register controls the power applied to the Watchdog Module module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCWD**, **SCGCWD** and **DCGCWD** registers. If the Rn, Sn, or Dn bit of the respective **RCGCWD**, **SCGCWD** and **DCGCWD** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCWD** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCWD**, **SCGCWD** and **DCGCWD** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCWD** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

**Table 5-16. Module Power Control**

| Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register | Pn | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------------------------|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                                                | 0  | Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.<br><br>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the <b>RCGCx</b> , <b>SCGCx</b> , or <b>DCGCx</b> register is a 1 or the P0 bit is changed to a 1.<br><br>Software must re-initialize the peripheral when re-enabled due to the loss of state. |
| 0                                                                | 1  | Module is powered, but does not receive a clock.<br><br>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.                                                                                                                                                                                                                                                                                                  |
| 1                                                                | X  | Module is powered and receives a clock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Register 141: 16/32-Bit General-Purpose Timer Power Control (PCTIMER), offset 0x904

**Important:** The Timer module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCTIMER** register controls the power applied to the Timer module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCTIMER**, **SCGCTIMER** and **DCGCTIMER** registers. If the Rn, Sn, or Dn bit of the respective **RCGCTIMER**, **SCGCTIMER** and **DCGCTIMER** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCTIMER** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCTIMER**, **SCGCTIMER** and **DCGCTIMER** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCTIMER** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

**Table 5-17. Module Power Control**

| Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register | Pn | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Register 142: General-Purpose Input/Output Power Control (PCGPIO), offset 0x908

**Important:** The GPIO modules do not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCGPIO** register controls the power applied to the GPIO module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCGPIO**, **SCGCGPIO** and **DCGCGPIO** registers. If the Rn, Sn, or Dn bit of the respective **RCGCGPIO**, **SCGCGPIO** and **DCGCGPIO** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCGPIO** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCGPIO**, **SCGCGPIO** and **DCGCGPIO** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCGPIO** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

**Table 5-18. Module Power Control**

| Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register | Pn | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------------------------|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                                                | 0  | Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.<br><br>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the <b>RCGCx</b> , <b>SCGCx</b> , or <b>DCGCx</b> register is a 1 or the P0 bit is changed to a 1.<br><br>Software must re-initialize the peripheral when re-enabled due to the loss of state. |
| 0                                                                | 1  | Module is powered, but does not receive a clock.<br><br>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.                                                                                                                                                                                                                                                                                                  |
| 1                                                                | X  | Module is powered and receives a clock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Register 143: Micro Direct Memory Access Power Control (PCDMA), offset 0x90C

**Important:** The  $\mu$ DMA module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCDMA** register controls the power applied to the DMA module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCDMA**, **SCGCDMA** and **DCGCDMA** registers. If the Rn, Sn, or Dn bit of the respective **RCGCDMA**, **SCGCDMA** and **DCGCDMA** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCDMA** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCDMA**, **SCGCDMA** and **DCGCDMA** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCDMA** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

**Table 5-19. Module Power Control**

| Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register | Pn | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------------------------|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                                                | 0  | Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.<br><br>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the <b>RCGCx</b> , <b>SCGCx</b> , or <b>DCGCx</b> register is a 1 or the P0 bit is changed to a 1.<br><br>Software must re-initialize the peripheral when re-enabled due to the loss of state. |
| 0                                                                | 1  | Module is powered, but does not receive a clock.<br><br>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.                                                                                                                                                                                                                                                                                                  |
| 1                                                                | X  | Module is powered and receives a clock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

In this case, the module is inactive.                                                                                       |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |             |   |                                                                                                                                                                                       |   |                                                                                                 |

## Register 144: External Peripheral Interface Power Control (PCEPI), offset 0x910

**Important:** The EPI module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCEPI** register controls the power applied to the EPI module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCEPI**, **SCGCEPI** and **DCGCEPI** registers. If the Rn, Sn, or Dn bit of the respective **RCGCEPI**, **SCGCEPI** and **DCGCEPI** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCEPI** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCEPI**, **SCGCEPI** and **DCGCEPI** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCEPI** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

**Table 5-20. Module Power Control**

| Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register | Pn | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Register 146: Universal Asynchronous Receiver/Transmitter Power Control (PCUART), offset 0x918

**Important:** The UART module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCUART** register controls the power applied to the UART module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCUART**, **SCGCUART** and **DCGCUART** registers. If the Rn, Sn, or Dn bit of the respective **RCGCUART**, **SCGCUART** and **DCGCUART** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCUART** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCUART**, **SCGCUART** and **DCGCUART** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCUART** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

**Table 5-22. Module Power Control**

| Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register | Pn | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
