

# 5.5-V TO 52-V INPUT, CURRENT-MODE BOOST CONTROLLER

Check for Samples: TPS40210-HT

#### **FEATURES**

•	For Boost, Flyback, SEPIC, LED Driver
	Applications

- Wide Input Operating Voltage: 5.5 V to 52 V
- Adjustable Oscillator Frequency
- Fixed-Frequency Current-Mode Control
- Internal Slope Compensation
- Integrated Low-Side Driver
- Programmable Closed-Loop Soft Start
- Overcurrent Protection
- External Synchronization Capable
- Reference Voltage: 700 mV
- Low-Current Disable Function

# **APPLICATIONS**

- Down-Hole Drilling
- High Temperature Environments

# SUPPORTS EXTREME TEMPERATURE APPLICATIONS

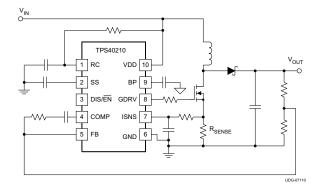

- Controlled Baseline
- One Assembly/Test Site
- One Fabrication Site
- Available in Extreme (–55°C/210°C)
   Temperature Range<sup>(1)</sup>
- Extended Product Life Cycle
- Extended Product-Change Notification
- Product Traceability
- Texas Instruments high temperature products utilize highly optimized silicon (die) solutions with design and process enhancements to maximize performance over extended temperatures.
- (1) Custom temperature ranges available

## **DESCRIPTION**

The TPS40210 is a wide input voltage (5.5 V to 52 V) non-synchronous boost controller. It is suitable for topologies that require a grounded source N-channel FET, including boost, flyback, SEPIC, and various LED driver applications. Device features include programmable soft start, overcurrent protection with automatic retry, and programmable oscillator frequency. Current-mode control provides improved transient response and simplified loop compensation.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

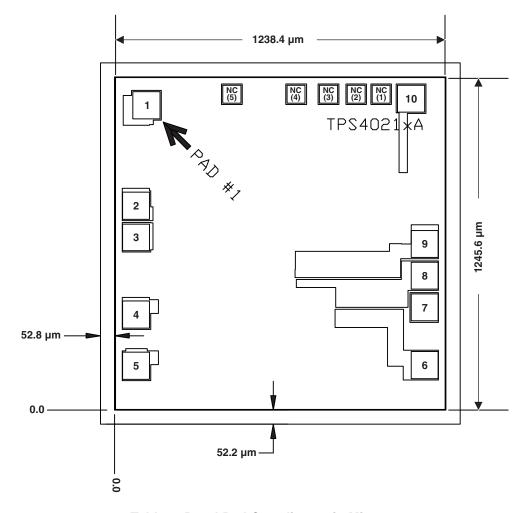

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

#### **DEVICE RATINGS**

## **ABSOLUTE MAXIMUM RATINGS**

over operating free-air temperature range unless otherwise noted (1)

		VDD	–0.3 V to 52 V
Input voltage range		RC, SS, FB, DIS/EN	–0.3 V to 10 V
		ISNS	-0.3 V to 8 V
	Output voltage range	COMP, BP, GDRV	–0.3 V to 9 V
$T_{J}$	Operating junction temperature range	−55°C to 210°C	
T <sub>stg</sub>	Storage temperature range	–55°C to 210°C	

Stresses beyond those listed under "absolute maximum ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under "recommended operating conditions" is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

## **CURRENT SENSE AMPLIFIER GAIN**

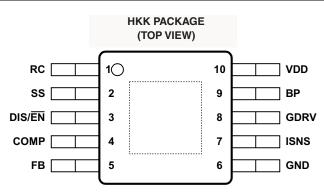

# **DEVICE INFORMATION**

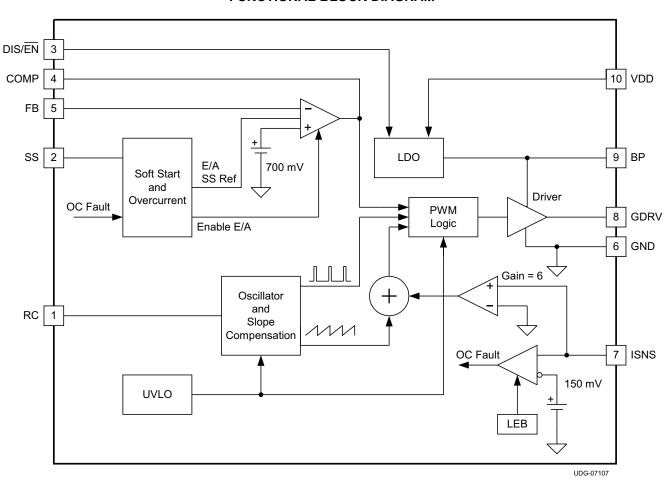

## **TERMINAL FUNCTIONS**

TERMINAL		1/0	DESCRIPTION					
NAME	NO.	1/0	DESCRIPTION					
BP	9	0	Regulator output. Connect a 1.0-μF bypass capacitor from this pin to GND.					
COMP	4	0	Error amplifier output. Connect control loop compensation network between COMP pin and FB pin.					
DIS/EN	3	I	Disable/enable. Pulling this pin high places the part into a shutdown mode. Shutdown mode is characterized by a very low quiescent current. While in shutdown mode, the functionality of all blocks is disabled, and the BP regulator is shut down. This pin has an internal 1-M $\Omega$ pulldown resistor to GND. Leaving this pin unconnected enables the device.					
FB	5	I	Error amplifier inverting input. Connect a voltage divider from the output to this pin to set the output voltage. Compensation network is connected between this pin and COMP.					
GDRV	8	0	Connect the gate of the power N-channel MOSFET to this pin.					
GND	6	-	Device ground					
ISNS	7	I	Current sense. Connect an external current sensing resistor between this pin and GND. The voltage on this pin is used to provide current feedback in the control loop and detect an overcurrent condition. An overcurrent condition is declared when ISNS pin voltage exceeds the overcurrent threshold voltage, 150 mV typical.					
RC	1	I	Switching frequency setting. Connect capacitor from RC pin to GND. Connect a resistor from RC pin to VDD of the IC power supply and a capacitor from RC to GND.					
SS	2	_	Soft-start time programming. Connect capacitor from SS pin to GND to program converter soft-start time. This pin also functions as a timeout timer when the power supply is in an overcurrent condition.					
VDD	10	I	System input voltage. Connect a local bypass capacitor from this pin to GND. Depending on the amount of required slope compensation, this pin can be connected to the converter output. See <i>Application Information</i> section for additional details.					

# **FUNCTIONAL BLOCK DIAGRAM**

#### APPLICATION INFORMATION

#### Minimum On-Time and Off-Time Considerations

The TPS40210 has a minimum off time of approximately 200 ns and a minimum on time of 300 ns. These two constraints place limitations on the operating frequency that can be used for a given input-to-output conversion ratio. See Figure 3 for the maximum frequency that can be used for a given duty cycle.

The duty cycle at which the converter operates is dependent on the mode in which the converter is running. If the converter is running in discontinuous conduction mode, the duty cycle varies with changes to the load much more than it does when running in continuous conduction mode.

In continuous conduction mode, the duty cycle is related primarily to the input and output voltages.

$$\frac{V_{OUT} + V_{D}}{V_{IN}} = \frac{1}{1 - D} \tag{1}$$

$$D = \left(1 - \left(\frac{V_{IN}}{V_{OUT} + V_{D}}\right)\right)$$
 (2)

In discontinuous mode, the duty cycle is a function of the load, input and output voltages, inductance, and switching frequency.

$$D = \frac{2 \times (V_{OUT} + V_D) \times I_{OUT} \times L \times f_{SW}}{(V_{IN})^2}$$
(3)

All converters using a diode as the freewheeling or catch component have a load current level at which they transition from discontinuous conduction to continuous conduction. This is the point at which the inductor current falls to zero. At higher load currents, the inductor current does not fall to zero but remains flowing in a positive direction and assumes a trapezoidal wave shape as opposed to a triangular wave shape. This load boundary between discontinuous conduction and continuous conduction can be found for a set of converter parameters as shown in Equation 4.

$$I_{OUT(crit)} = \frac{\left(V_{OUT} + V_D - V_{IN}\right) \times \left(V_{IN}\right)^2}{2 \times \left(V_{OUT} + V_D\right)^2 \times f_{SW} \times L}$$
(4)

For loads higher than the result of Equation 4, the duty cycle is given by Equation 2, and for loads less than the results of Equation 4, the duty cycle is given Equation 3. For Equation 1 through Equation 4, the variable definitions are as follows:

- V<sub>OUT</sub> is the output voltage of the converter in V
- V<sub>D</sub> is the forward conduction voltage drop across the rectifier or catch diode in V
- V<sub>IN</sub> is the input voltage to the converter in V
- I<sub>OUT</sub> is the output current of the converter in A
- L is the inductor value in H
- f<sub>SW</sub> is the switching frequency in Hz

# **Setting the Oscillator Frequency**

The oscillator frequency is determined by a resistor and capacitor connected to the RC pin of the TPS40210. The capacitor is charged to a level of approximately  $V_{VDD}/20$  by current flowing through the resistor and is then discharged by a transistor internal to the TPS40210. The required resistor for a given oscillator frequency is found from either Figure 2 or Equation 5.

$$R_T = \frac{1}{5.8 \times 10^{-8} \times f_{SW} \times C_T + 8 \times 10^{-10} \times f_{SW}^2 + 1.4 \times 10^{-7} \times f_{SW} - 1.5 \times 10^{-4} + 1.7 \times 10^{-6} \times C_T - 4 \times 10^{-9} \times C_T^2}$$

where

- $R_T$  is the timing resistance in  $k\Omega$
- f<sub>SW</sub> is the switching frequency in kHz
- C<sub>T</sub> is the timing capacitance in pF

(5)

For most applications, a capacitor in the range of 68 pF to 120 pF gives the best results. Resistor values should be limited to between 100 k $\Omega$  and 1 M $\Omega$  as well. If the resistor value falls below 100 k $\Omega$ , decrease the capacitor size and recalculate the resistor value for the desired frequency. As the capacitor size decreases below 47 pF, the accuracy of Equation 5 degrades, and empirical means may be needed to fine tune the timing component values to achieve the desired switching frequency.

# Synchronizing the Oscillator

The TPS40210 can be synchronized to an external clock source. Figure 21 shows the functional diagram of the oscillator. When synchronizing the oscillator to an external clock, the RC pin must be pulled below 150 mV for 20 ns or more. The external clock frequency must be higher than the free running frequency of the converter as well. When synchronizing the controller, if the RC pin is held low for an excessive amount of time, erratic operation may occur. The maximum amount of time that the RC pin should be held low is 50% of a nominal output pulse, or 10% of the period of the synchronization frequency.

Under circumstances where the duty cycle is less than 50%, a Schottky diode connected from the RC pin to an external clock may be used to synchronize the oscillator. The cathode of the diode is connected to the RC pin. The trip point of the oscillator is set by an internal voltage divider to be 1/20 of the input voltage. The clock signal must have an amplitude higher than this trip point. When the clock goes low, it allows the reset current to restart the RC ramp, synchronizing the oscillator to the external clock. This provides a simple single-component method for clock synchronization.

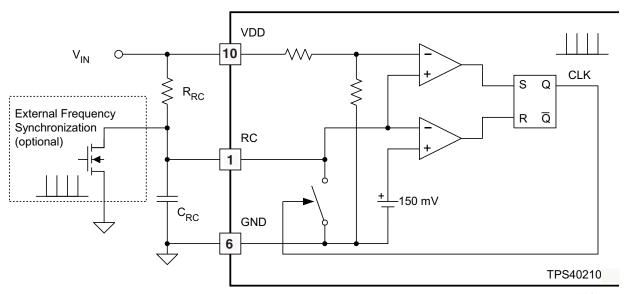

Figure 21. Oscillator Functional Diagram

UDG-0806

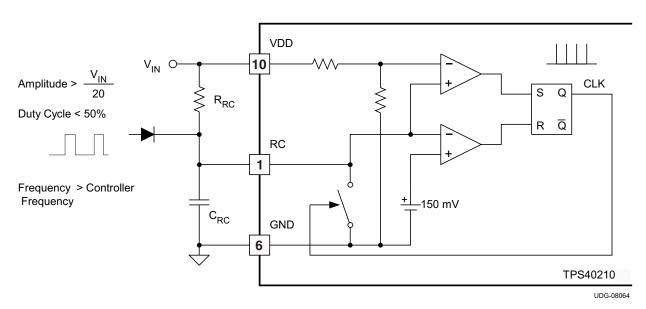

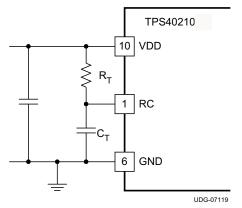

Figure 22. Diode Connected Synchronization

#### **Current Sense and Overcurrent**

The TPS40210 are current-mode controllers and use a resistor in series with the source terminal power FET to sense current for both the current-mode control and overcurrent protection. The device enters a current-limit state if the voltage on the ISNS pin exceeds the current-limit threshold voltage  $V_{\rm ISNS(oc)}$  from the electrical specifications table. When this happens, the controller discharges the SS capacitor through a relatively high impedance and then attempts to restart. The amount of output current that causes this to happen is dependent on several variables in the converter.

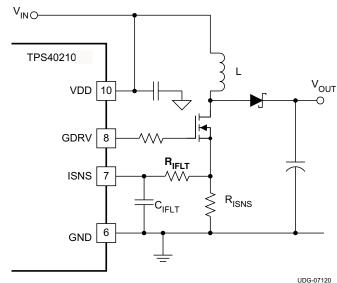

Figure 23. Oscillator Components

Figure 24. Current Sense Components

The load current overcurrent threshold is set by proper choice of RISNS. If the converter is operating in discontinuous mode the current sense resistor is found in Equation 6.

$$R_{ISNS} = \frac{f_{SW} \times L \times V_{ISNS(oc)}}{\sqrt{2 \times L \times f_{SW} \times I_{OUT(oc)} \times (V_{OUT} + V_D - V_{IN})}}$$
(6)

If the converter is operating in continuous conduction mode R<sub>ISNS</sub> can be found in Equation 7.

$$R_{ISNS} = \frac{V_{ISNS}}{\left(\frac{I_{OUT}}{1-D}\right) + \left(\frac{I_{RIPPLE}}{2}\right)} = \frac{V_{ISNS}}{\left(\frac{I_{OUT}}{\left(1-D\right)}\right) + \left(\frac{D \times V_{IN}}{2 \times f_{SW} \times L}\right)}$$

where

- $R_{ISNS}$  is the value of the current sense resistor in  $\Omega$ .
- V<sub>ISNS(oc)</sub> is the overcurrent threshold voltage at the ISNS pin (from electrical specifications)
- D is the duty cycle (from Equation 2)
- f <sub>SW</sub> is the switching frequency in Hz
- V<sub>IN</sub> is the input voltage to the power stage in V (see text)
- . L is the value of the inductor in H
- I<sub>OUT</sub>(oc) is the desired overcurrent trip point in A
- V<sub>D</sub> is the drop across the diode in Figure 24

(7)The TPS40210 have a fixed undervoltage lockout (UVLO) that allows the controller to start at a typical input

voltage of 4.25 V. If the input voltage is slowly rising, the converter might have less than its designed nominal input voltage available when it has reached regulation. As a result, this may decreases the apparent current-limit load current value and must be taken into consideration when selecting R<sub>ISNS</sub>. The value of V<sub>IN</sub> used to calculate R<sub>ISNS</sub> must be the value at which the converter finishes startup. The total converter output current at startup is the sum of the external load current and the current required to charge the output capacitor(s). See the Soft Start section of this data sheet for information on calculating the required output capacitor charging current.

The topology of the standard boost converter has no method to limit current from the input to the output in the event of a short circuit fault on the output of the converter. If protection from this type of event is desired, it is necessary to use some secondary protection scheme such as a fuse or rely on the current limit of the upstream power source.

#### **Current Sense and Sub-Harmonic Instability**

A characteristic of peak current-mode control results in a condition where the current control loop can exhibit instability. This results in alternating long and short pulses from the pulse-width modulator. The voltage loop maintains regulation and does not oscillate, but the output ripple voltage increases. The condition occurs only when the converter is operating in continuous conduction mode, and the duty cycle is 50% or greater. The cause of this condition is described in Texas Instruments literature number SLUA101, available at www.ti.com. The remedy for this condition is to apply a compensating ramp from the oscillator to the signal going to the pulse-width modulator. In the TPS40210, the oscillator ramp is applied in a fixed amount to the pulse-width modulator. The slope of the ramp is given in Equation 8.

$$s_{e} = f_{SW} \times \left(\frac{V_{VDD}}{20}\right) \tag{8}$$

To ensure that the converter does not enter into sub-harmonic instability, the slope of the compensating ramp signal must be at least half of the down slope of the current ramp signal. Because the compensating ramp is fixed in the TPS40210, this places a constraint on the selection of the current sense resistor.

The down slope of the current sense wave form at the pulse-width modulator is described in Equation 9.

$$m2 = \frac{A_{CS} \times R_{ISNS} \times (V_{OUT} + V_D - V_{IN})}{L}$$
(9)

Submit Documentation Feedback

Copyright © 2010, Texas Instruments Incorporated

Since the slope compensation ramp must be at least half, and preferably equal to the down slope of the current sense waveform seen at the pulse-width modulator, a maximum value is placed on the current sense resistor when operating in continuous mode at 50% duty cycle or greater. For design purposes, some margin should be applied to the actual value of the current sense resistor. As a starting point, the actual resistor chosen should be 80% or less that the value calculated in Equation 10. This equation calculates the resistor value that makes the slope compensation ramp equal to one half of the current ramp downslope. Values no more than 80% of this result are acceptable.

$$R_{ISNS(max)} = \frac{V_{VDD} \times L \times \textit{f}_{SW}}{60 \times \left(V_{OUT} + V_{D} - V_{IN}\right)}$$

#### where

- S<sub>e</sub> is the slope of the voltage compensating ramp applied to the pulse-width modulator in V/s
- f<sub>SW</sub> is the switching frequency in Hz
- V<sub>VDD</sub> is the voltage at the VDD pin in V
- m2 is the down slope of the current sense waveform seen at the pulse-width modulator in V/s
- R<sub>ISNS</sub> is the value of the current sense resistor in Ω
- V<sub>OUT</sub> is the converter output voltage V<sub>IN</sub> is the converter power stage input voltage
- V<sub>D</sub> is the drop across the diode in Figure 24

(10)

It is possible to increase the voltage compensation ramp slope by connecting the VDD pin to the output voltage of the converter instead of the input voltage as shown in Figure 24. This can help in situations where the converter design calls for a large ripple current value in relation to the desired output current limit setting.

#### **NOTE**

Connecting the VDD pin to the output voltage of the converter affects the startup voltage of the converter since the controller undervoltage lockout (UVLO) circuit monitors the VDD pin and senses the input voltage less the diode drop before startup. The effect is to increase the startup voltage by the value of the diode voltage drop.

If an acceptable  $R_{\text{ISNS}}$  value is not available, the next higher value can be used and the signal from the resistor divided down to an acceptable level by placing another resistor in parallel with  $C_{\text{ISNS}}$ .

## **Current Sense Filtering**

In most cases, a small filter placed on the ISNS pin improves performance of the converter. These are the components  $R_{\text{IFLT}}$  and  $C_{\text{IFLT}}$  in Figure 24. The time constant of this filter should be approximately 10% of the nominal pulse width of the converter. The pulse width can be found using Equation 11.

$$t_{ON} = \frac{D}{f_{SW}} \tag{11}$$

The suggested time constant is then

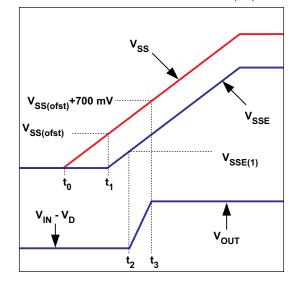

$$R_{IFLT} \times C_{IFLT} = 0.1 \times t_{ON}$$
(12)

The range of  $R_{IFLT}$  should be from about 1 k $\Omega$  to 5 k $\Omega$  for best results. Higher values can be used, but this raises the impedance of the ISNS pin connection more than necessary and can lead to noise-pickup issues in some layouts.  $C_{ISNS}$  should be located as close as possible to the ISNS pin as well to provide noise immunity.

#### **Soft Start**

The soft-start feature of the TPS40210 is a closed-loop soft start, meaning that the output voltage follows a linear ramp that is proportional to the ramp generated at the SS pin. This ramp is generated by an internal resistor connected from the BP pin to the SS pin and an external capacitor connected from the SS pin to GND. The SS pin voltage ( $V_{SS}$ ) is level shifted down by approximately  $V_{SS(ofst)}$  (approximately 1 V) and sent to one of the "+" input (the "+" input with the lowest voltage dominates) of the error amplifier. When this level-shifted voltage ( $V_{SSE}$ ) starts to rise at time  $t_1$  (see Figure 25), the output voltage that the controller expects rises as well. Since  $V_{SSE}$  starts at near 0 V, the controller attempts to regulate the output voltage from a starting point of zero volts. It

cannot do this, due to the converter architecture. The output voltage starts from the input voltage less the drop across the diode  $(V_{IN}-V_D)$  and rises from there. The point at which the output voltage starts to rise  $(t_2)$  is when the  $V_{SSE}$  ramp passes the point where it is commanding more output voltage than  $(V_{IN}-V_D)$ . This voltage level is labeled  $V_{SSE(1)}$ . The time required for the output voltage to ramp from a theoretical zero to the final regulated value (from  $t_1$  to  $t_3$ ) is determined by the time it takes for the capacitor connected to the SS pin  $(C_{SS})$  to rise through a 700-mV range, beginning at  $V_{SS(ofst)}$  above GND.

(13)

www.ti.com SLVSAD8 – JUNE 2010

The required capacitance for a given soft start time  $t_3 - t_1$  in Figure 25 is calculated in Equation 13.

$$C_{SS} = \frac{t_{SS}}{R_{SS} \times In \left( \frac{V_{BP} - V_{SS(ofst)}}{V_{BP} - \left(V_{SS(ofst)} + V_{FB}\right)} \right)}$$

#### where

- t<sub>SS</sub> is the soft-start time
- $R_{SS(chg)}$  is the SS charging resistance in  $\Omega$ , typically 500 k $\Omega$
- C<sub>SS</sub> is the value of the capacitor on the SS pin, in F
- V<sub>BP</sub> is the value of the voltage on the BP pin in V
- V<sub>SS(ofst)</sub> is the approximate level shift from the SS pin to the error amplifier (~1 V)
- V<sub>FB</sub> is the error amplifier reference voltage, 700 mV typical

Note that  $t_{SS}$  is the time it takes for the output voltage to rise from 0 V to the final output voltage. Also note the tolerance on  $R_{SS(chg)}$  given in the electrical specifications table. This contributes to some variability in the output voltage rise time, and margin must be applied to account for it in design.

Also take note of  $V_{BP}$ . Its value varies depending on input conditions. For example, a converter operating from a slowly rising input initializes  $V_{BP}$  at a fairly low value and increases during the entire startup sequence. If the controller has a voltage above 8 V at the input and the DIS pin is used to stop and then restart the converter,  $V_{BP}$  is approximately 8 V for the entire startup sequence. The higher the voltage on BP, the shorter the startup time is and conversely, the lower the voltage on BP, the longer the startup time is.

The soft-start time ( $t_{SS}$ ) must be chosen long enough so that the converter can start up without going into an overcurrent state. Since the overcurrent state is triggered by sensing the peak voltage on the ISNS pin, that voltage must be kept below the overcurrent threshold voltage  $V_{ISNS(oc)}$ . The voltage on the ISNS pin is a function of the load current of the converter, the rate of rise of the output voltage and the output capacitance, and the current sensing resistor. The total output current that must be supported by the converter is the sum of the charging current required by the output capacitor and any external load that must be supplied during startup. This current must be less than the  $I_{OUT(oc)}$  value used in Equation 6 or Equation 7 (depending on the operating mode of the converter) to determine the current sense resistor value.

In these equations, the actual input voltage at the time that the controller reaches the final output voltage is the important input voltage to use in the calculations. If the input voltage is slowly rising and is at less than the nominal input voltage when the startup time ends, the output current limit is less than  $I_{OUT(oc)}$  at the nominal input voltage. The output capacitor charging current must be reduced (decrease  $C_{OUT}$  or increase the  $t_{SS}$ ) or  $I_{OUT(oc)}$  must be increased and a new value for  $R_{ISNS}$  calculated.

$$I_{C(chg)} = \left[ \frac{C_{OUT} \times V_{OUT}}{t_{SS}} \right]$$

$$t_{SS} > \left[ \frac{C_{OUT} \times V_{OUT}}{(I_{OUT(oc)} - I_{EXT})} \right]$$
(14)

#### where

- I<sub>C(chq)</sub> is the output capacitor charging current in A
- C<sub>OUT</sub> is the total output capacitance in F
- V<sub>OUT</sub> is the output voltage in V
- t<sub>SS</sub> is the soft start time from Equation 13
- I<sub>OUT(oc)</sub> is the desired over current trip point in A
- I<sub>EXT</sub> is any external load current in A

(15)

The capacitor on the SS pin ( $C_{SS}$ ) also plays a role in overcurrent functionality. It is used as the timer between restart attempts. The SS pin is connected to GND through a resistor,  $R_{SS(dchg)}$ , when the controller senses an overcurrent condition. Switching stops and nothing else happens until the SS pin discharges to the soft-start reset threshold,  $V_{SS(rst)}$ . At this point, the SS pin capacitor is allowed to charge again through the charging resistor  $R_{SS(chg)}$ , and the controller restarts from that point. The shortest time between restart attempts occurs when the SS pin discharges from  $V_{SS(ofst)}$  (approximately 1 V) to  $V_{SS(rst)}$  (150 mV) and then back to  $V_{SS(ofst)}$  and switching resumes. In actuality, this is a conservative estimate since switching does not resume until the  $V_{SSE}$  ramp rises to a point where it is commanding more output voltage than exists at the output of the controller. This occurs at some SS pin voltage greater than  $V_{SS(ofst)}$  and depends on the voltage that remains on the output overvoltage the converter while switching has been halted. The fastest restart time can be calculated by using Equation 16, Equation 17, and Equation 18.

$$t_{DCHG} = R_{SS(dchg)} \times C_{SS} \times In \left( \frac{V_{SS(ofst)}}{V_{SS(rst)}} \right)$$
(16)

$$t_{CHG} = R_{SS(chg)} \times C_{SS} \times In \left( \frac{\left( V_{BP} - V_{SS(rst)} \right)}{\left( V_{BP} - V_{SS(ofst)} \right)} \right) \tag{17}$$

$$t_{RSTRT(min)} = t_{CHG} + t_{DCHG}$$
 (18)

## **BP** Regulator

The TPS40210 has an on-board linear regulator that supplies power for the internal circuitry of the controller, including the gate driver. This regulator has a nominal output voltage of 8 V and must be bypassed with a  $1-\mu F$  capacitor. If the voltage at the VDD pin is less than 8 V, the voltage on the BP pin is also less, and the gate drive voltage to the external FET is reduced from the nominal 8 V. This should be considered when choosing a FET for the converter.

Connecting external loads to this regulator can be done, but care must be taken to ensure that the thermal rating of the device is observed, because there is no thermal shutdown feature in this controller. Exceeding the thermal ratings causes out-of-specification behavior and can lead to reduced reliability. The controller dissipates more power when there is an external load on the BP pin and is tested for dropout voltage for up to 5-mA load. When the controller is in the disabled state, the BP pin regulator also shuts off so loads connected there power down as well. When the controller is disabled with the DIS/EN pin, this regulator is turned off.

The total power dissipation in the controller can be calculated as follows. The total power is the sum of  $P_Q$ ,  $P_G$  and  $P_E$ .

$$P_{Q} = V_{VDD} \times I_{VDD(en)}$$
(19)

$$P_{G} = V_{VDD} \times Q_{g} \times f_{SW}$$
(20)

$$P_{F} = V_{VDD} \times I_{FXT}$$

#### where

- P<sub>O</sub> is the quiescent power of the device in W
- V<sub>VDD</sub> is the VDD pin voltage in V
- I<sub>VDD(en)</sub> is the quiescent current of the controller when enabled but not switching in A
- P<sub>G</sub> is the power dissipated by driving the gate of the FET in W
- Q<sub>a</sub> is the total gate charge of the FET at the voltage on the BP pin in C
- f SW is the switching frequency in Hz
- · PE is the dissipation caused be external loading of the BP pin in W
- I<sub>EXT</sub> is the external load current in A
   (21)

# Shutdown (DIS/EN Pin)

The DIS/EN pin is an active-high shutdown command for the controller. Pulling this pin above 1.2 V causes the controller to completely shut down and enter a low current consumption state. In this state, the regulator connected to the BP pin is turned off. There is an internal 1.1-M $\Omega$  pull-down resistor connected to this pin that keeps the pin at GND level when left floating. If this function is not used in an application, it is best to connect this pin to GND

## **Control Loop Considerations**

There are two methods to design a suitable control loop for the TPS40210. The first (and preferred, if equipment is available) is to use a frequency-response analyzer to measure the open-loop modulator and power stage gain and to then design compensation to fit that. The usage of these tools for this purpose is well documented with the literature that accompanies the tool and is not discussed here.

The second option is to make an initial guess at compensation, and then evaluate the transient response of the system to see if the compensation is acceptable to the application or not. For most systems, an adequate response can be obtained by simply placing a series resistor and capacitor (RFB and CFB) from the COMP pin to the FB pin as shown in Figure 28.

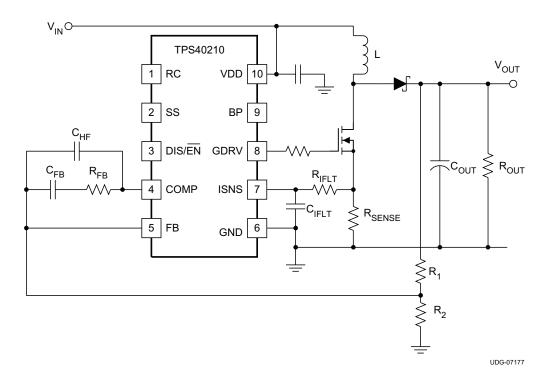

Figure 28. Basic Compensation Network

The natural phase characteristics of most capacitors used for boost outputs combined with the current mode control provide adequate phase margin when using this type of compensation. To determine an initial starting point for the compensation, the desired crossover frequency must be considered when estimating the control to output gain. The model used is a current source into the output capacitor and load.

When using these equations, the loop bandwidth should be no more than 20% of the switching frequency, f SW. A more reasonable loop bandwidth would be 10% of the switching frequency. Be sure to evaluate the transient response of the converter over the expected load range to ensure acceptable operation.

$$|K_{CO}| = g_{M} \times |Z_{OUT}(f_{CO})| = 19.1 \frac{A}{\sqrt{10}} \times 0.146 \Omega = 2.80$$

$$g_{M} = \frac{0.13 \times \sqrt{L \times \frac{f_{SW}}{R_{OUT}}}}{(R_{ISNS})^{2} \times (120 \times R_{ISNS} + L \times f_{SW})} = \frac{0.13 \times \sqrt{10 \,\mu\text{H} \times \frac{600 \,k\text{Hz}}{240 \,\Omega}}}{(12m\Omega)^{2} \times (120 \times 12m\Omega + 10 \,\mu\text{H} \times 600 \,k\text{Hz})} = 19.1 \frac{A}{\sqrt{100 \,\mu\text{Hz}}}$$

(23)

(24)

www.ti.com SLVSAD8 – JUNE 2010

$$\left|Z_{OUT}\right| = R_{OUT} \times \sqrt{\frac{\left(1 + \left(2\pi \times f_{L} \times R_{ESR} \times C_{OUT}\right)^{2}\right)}{1 + \left(\left(R_{OUT}\right)^{2} + 2 \times R_{OUT} \times R_{ESR} + \left(R_{ESR}\right)^{2}\right) \cdot \left(2\pi \times f_{L} \times C_{OUT}\right)^{2}}}$$

#### where

- K<sub>CO</sub> is the control to output gain of the converter, in V/V
- g<sub>M</sub> is the transconductance of the power stage and modulator, in S
- R<sub>OUT</sub> is the output load equivalent resistance, in Ω
- $Z_{OUT}$  is the output impedance, including the output capacitor, in  $\Omega$
- $R_{ISNS}$  is the value of the current sense resistor, in  $\Omega$
- L is the value of the inductor, in H
- $C_{OUT}$  is the value of the output capacitance, in  $\mu F$
- $R_{ESR}$  is the equivalent series resistance of  $C_{OUT}$ , in  $\Omega$
- f SW is the switching frequency, in Hz
- f<sub>L</sub> is the desired crossover frequency for the control loop, in Hz

These equations assume that the operation is discontinuous and that the load is purely resistive. The gain in continuous conduction can be found by evaluating Equation 23 at the resistance that gives the critical conduction current for the converter. Loads that are more like current sources give slightly higher gains than predicted here. To find the gain of the compensation network required for a control loop of bandwidth  $f_{\rm L}$ , take the reciprocal of Equation 22.

$$K_{COMP} = \frac{1}{|K_{CO}|} = \frac{1}{2.80} = 0.356$$
 (25)

The GBWP of the error amplifier is only specified to be at least 1.5 MHz. If  $K_{COMP}$  multiplied by the  $f_L$  is greater than 750 kHz, reduce the desired loop crossover frequency until this condition is satisfied. This ensures that the high-frequency pole from the error amplifier response with the compensation network in place does not cause excessive phase lag at the  $f_L$  and decrease phase margin in the loop.

The R-C network connected from COMP to FB places a zero in the compensation response. That zero should be approximately  $1/10^{th}$  of the desired crossover frequency,  $f_L$ . With that being the case,  $R_{FB}$  and  $C_{FB}$  can be found from Equation 26 and Equation 27

$$R_{FB} = \frac{R1}{|K_{CO}|} = R1 \times K_{COMP}$$
(26)

$$C_{FB} = \frac{10}{2\pi \times f_L \times R_{FB}}$$

#### where

• R1 is in f<sub>L</sub> is the loop crossover frequency desired, in Hz.

Thought not strictly necessary, it is recommended that a capacitor be added between COMP and FB to provide high-frequency noise attenuation in the control loop circuit. This capacitor introduces another pole in the compensation response. The allowable location of that pole frequency determines the capacitor value. As a starting point, the pole frequency should be  $10 \times f_1$ . The value of  $C_{HF}$  can be found from Equation 28.

$$C_{HF} = \frac{1}{20\pi \times f_L \times R_{FB}}$$
 (28)

(29)

SLVSAD8 – JUNE 2010 www.ti.com

The error amplifier GBWP will usually be higher, but is ensured by design to be at least 1.5 MHz. If the gain required in Equation 25 multiplied by 10 times the desired control loop crossover frequency, the high-frequency pole introduced by  $C_{HF}$  is overridden by the error amplifier capability and the effective pole is lower in frequency. If this is the case,  $C_{HF}$  can be made larger to provide a consistent high-frequency roll off in the control loop design. Equation 29 calculates the required  $C_{HF}$  in this case.

$$C_{HF} = \frac{1}{2\pi \times 1.5 \times (10)^6 \times R_{FB}}$$

where

- $C_{HF}$  is the high-frequency roll-off capacitor value in  $\mu F$
- R<sub>FB</sub> is the mid-band gain-setting resistor value in  $\Omega$

#### **Gate Drive Circuit**

Some applications benefit from the addition of a resistor connected between the GDRV pin and the gate of the switching MOSFET. In applications that have particularly stringent load regulation (under 0.75%) requirements and operate from input voltages above 5 V, or are sensitive to pulse jitter in the discontinuous conduction region, this resistor is recommended. The recommended starting point for the value of this resistor can be calculated from Equation 30.

$$R_G = \frac{105}{Q_G}$$

where

- Q<sub>G</sub> is the MOSFET total gate charge at 8-V V<sub>GS</sub> in nC.
- R<sub>G</sub> is the suggested starting point gate resistance in Ω.

  (30)

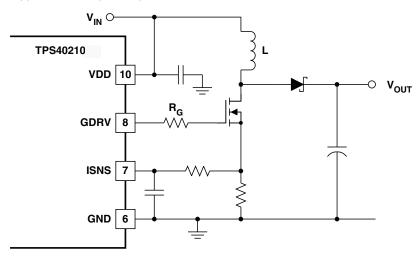

Figure 29. Gate Drive Resistor

#### **TPS40211**

The only difference between the TPS40210 and the TPS40211 is the reference voltage that the error amplifier uses to regulate the output voltage. The TPS40211 uses a 260-mV reference and is intended for applications where the output is actually a current instead of a regulated voltage. A typical example of an application of this type is an LED driver. An example schematic is shown in Figure 30.

24 Submit Do

UDG-07196

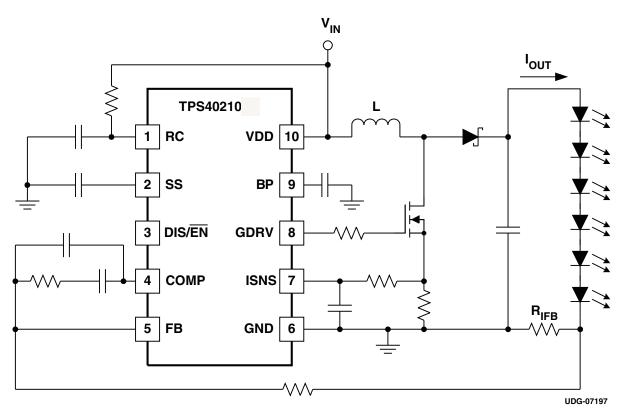

Figure 30. Typical LED Drive Schematic

The current in the LED string is set by the choice of the resistor R<sub>ISNS</sub> as shown in Equation 31.

$$R_{IFB} = \frac{V_{FB}}{I_{OUT}}$$

## where

- $R_{IFB}$  is the value of the current sense resistor for the LED string in  $\Omega$ .
- V<sub>FB</sub> is the reference voltage for the TPS40211 in V (0.260 V typ).
- I<sub>OUT</sub> is the desired DC current in the LED string in A. (31)

## Step-By-Step Design Procedure

## **Duty Cycle Estimation**

The duty cycle of the main switching MOSFET is estimated using Equation 32 and Equation 33.

$$D_{MIN} \approx \frac{V_{OUT} - V_{IN(max)} + V_{FD}}{V_{OUT} + V_{FD}} = \frac{24 \, V - 14 \, V + 0.5 \, V}{24 \, V + 0.5 \, V} = 42.8\% \tag{32}$$

$$D_{MAX} \approx \frac{V_{OUT} - V_{IN(min)} + V_{FD}}{V_{OUT} + V_{FD}} = \frac{24 \, V - 8 \, V + 0.5 \, V}{24 \, V + 0.5 \, V} = 67.3\% \tag{33}$$

Using and estimated forward drop of 0.5 V for a Schottky rectifier diode, the approximate duty cycle is 42.8% (minimum) to 67.3% (maximum).

#### **Inductor Selection**

The peak-to-peak ripple is limited to 30% of the maximum output current.

$$I_{Lrip(max)} = 0.3 \times \frac{I_{OUT(max)}}{1 - D_{MIN}} = 0.3 \times \frac{2}{1 - 0.428} = 1.05 \,A \tag{34}$$

The minimum inductor size can be estimated using Equation 35.

$$L_{MIN} \gg \frac{V_{IN(max)}}{I_{Lrip(max)}} \times D_{MIN} \times \frac{1}{f_{SW}} = \frac{14 \text{ V}}{1.05 \text{ A}} \times 0.428 \times \frac{1}{600 \text{ kHz}} = 9.5 \,\mu\text{H}$$
(35)

The next higher standard inductor value of 10 μH is selected. The ripple current is estimated by Equation 36.

$$I_{\text{RIPPLE}} \approx \frac{V_{\text{IN}}}{L} \times D \times \frac{1}{f_{\text{SW}}} = \frac{12 \text{ V}}{10 \,\mu\text{H}} \times 0.50 \times \frac{1}{600 \,\text{kHz}} = 1.02 \,\text{A}$$
 (36)

$$I_{\text{RIPPLE(Vinmin)}} \approx \frac{V_{\text{IN}}}{L} \times D \times \frac{1}{f_{\text{SW}}} = \frac{8 \, V}{10 \, \mu \text{H}} \times 0.673 \times \frac{1}{600 \, \text{kHz}} = 0.89 \, \text{A}$$
 (37)

The worst-case peak-to-peak ripple current occurs at 50% duty cycle and is estimated as 1.02 A. Worst-case RMS current through the inductor is approximated by Equation 38.

$$I_{Lrms} = \sqrt{\left(I_{L(avg)}\right)^{2} + \left(\frac{1}{12}I_{RIPPLE}\right)^{2}} \approx \sqrt{\left(\frac{I_{OUT(max)}}{1 - D_{MAX}}\right)^{2} + \left(\frac{1}{12}I_{RIPPLE(VINmin)}\right)^{2}} = \sqrt{\left(\frac{2}{1 - 0.673}\right)^{2} + \left(\left(\frac{1}{12}\right) \times 0.817A\right)^{2}} = 6.13 \text{ Arms}$$
(38)

The worst case RMS inductor current is 6.13 Arms. The peak inductor current is estimated by Equation 39.

Submit Documentation Feedback

$$I_{Lpeak} \approx \frac{I_{OUT(max)}}{1 - D_{MAX}} + \left(\frac{1}{2}\right)I_{RIPPLE(Vinmin)} = \frac{2}{1 - 0.673} + \left(\frac{1}{2}\right)0.718 = 6.57 \,\text{A}$$
(39)

A 10-μH inductor with a minimum RMS current rating of 6.13 A and minimum saturation current rating of 6.57 A must be selected. A TDK RLF12560T-100M-7R5 7.5-A 10-μH inductor is selected.

This inductor power dissipation is estimated by Equation 40.

$$P_L \approx (I_{Lrms})^2 \times DCR$$
 (40)

The TDK RLF12560T-100M-7R5 12.4-m $\Omega$  DCR dissipates 466 mW of power.

#### **Rectifier Diode Selection**

A low-forward voltage drop Schottky diode is used as a rectifier diode to reduce its power dissipation and improve efficiency. Using 80% derating, on  $V_{OUT}$  for ringing on the switch node, the rectifier diode minimum reverse break-down voltage is given by Equation 41.

$$V_{(BR)R(min)} \ge \frac{V_{OUT}}{0.8} = 1.25 \times V_{OUT} = 1.25 \times 24 \text{ V} = 30 \text{ V}$$
 (41)

The diode must have reverse breakdown voltage greater than 30 V. The rectifier diode peak and average currents are estimated by Equation 42 and Equation 43.

$$I_{D(avg)} \approx I_{OUT(max)} = 2A$$
(42)

$$I_{D(peak)} = I_{L(peak)} = 6.57 A \tag{43}$$

For this design, 2-A average and 6.57-A peak is

The power dissipation in the diode is estimated by Equation 44.

$$P_{D(max)} \approx V_F \times I_{OUT(max)} = 0.5 \text{ V} \times 2 \text{ A} = 1 \text{W}$$
(44)

For this design, the maximum power dissipation is estimated as 1 W. Reviewing 30-V and 40-V Schottky diodes, the MBRS340T3 40-V 3-A diode in an SMC package is selected. This diode has a forward voltage drop of 0.48 V at 6 A, so the conduction power dissipation is approximately 960 mW, less than half its rated power dissipation.

#### **Output Capacitor Selection**

Output capacitors must be selected to meet the required output ripple and transient specifications.

$$C_{OUT} = 8 \frac{I_{OUT} \times D}{V_{OUT(ripple)}} \times \frac{1}{f_{SW}} = 8 \left( \frac{2A \times 0.673}{500 \,\text{mV}} \right) \times \frac{1}{600 \,\text{kHz}} = 35 \,\mu\text{F}$$
(45)

$$ESR = \frac{7}{8} \times \frac{V_{OUT(ripple)}}{I_{L(peak)} - I_{OUT}} = \frac{7}{8} \times \frac{500 \,\text{mV}}{6.57 \,\text{A} - 2 \,\text{A}} = 95 \,\text{m}\Omega \tag{46}$$

A Panasonic EEEFC1V330P 35-V 33- $\mu$ F, 120-m $\Omega$  bulk capacitor and 6.8- $\mu$ F ceramic capacitor is selected to provide the required capacitance and ESR at the switching frequency. The combined capacitances of 39.8  $\mu$ F and 60 m $\Omega$  are used in compensation calculations.

#### **Input Capacitor Selection**

Since a boost converter has continuous input current, the input capacitor senses only the inductor ripple current. The input capacitor value can be calculated by Equation 47 and Equation 48.

$$C_{\text{IN}} > \frac{I_{\text{L}(\text{ripple})}}{4 \times V_{\text{IN}(\text{ripple})} \times f_{\text{SW}}} = \frac{1.02 \,\text{A}}{4 \times 60 \,\text{mV} \times 600 \,\text{kHz}} = 7.0 \,\mu\text{F} \tag{47}$$

$$ESR < \frac{V_{IN(ripple)}}{2 \times I_{L(ripple)}} = \frac{60 \,\text{mV}}{2 \times 1.02 \,\text{A}} = 30 \,\text{m}\Omega \tag{48}$$

For this design, to meet a maximum input ripple of 60 mV, a minimum 7.0- $\mu$ F input capacitor with ESR less than 30 m $\Omega$  is needed. A 10- $\mu$ F X7R ceramic capacitor is selected.

#### **Current Sense and Current Limit**

The maximum allowable current sense resistor value is limited by both the current limit and sub-harmonic stability. These two limitations are given by Equation 49 and Equation 50.

$$R_{ISNS} < \frac{V_{OCP(min)}}{1.1 \times \left(I_{L(peak)} + I_{Drive}\right)} = \frac{110 \,\text{mV}}{1.1 \times 6.57 \,\text{A} + 0.50 \,\text{A}} = 14.2 \,\text{m}\Omega$$
(49)

$$R_{ISNS} < \frac{VDD_{MAX} \times L \times f_{SW}}{60 \times (V_{OUT} + V_{fd} - V_{IN})} = \frac{14 \text{ V} \times 10 \,\mu\text{H} \times 600 \,\text{kHz}}{60 \times (24 \text{ V} + 0.48 \text{ V} - 14 \text{ V})} = 133 \text{m}\Omega \tag{50}$$

The current limit requires a resistor less than 14.2 m $\Omega$ , and stability requires a sense resistor less than 133 m $\Omega$ . A 10-m $\Omega$  resistor is selected. Approximately 2-m $\Omega$  of routing resistance is added in compensation calculations.

#### **Current Sense Filter**

To remove switching noise from the current sense, an R-C filter is placed between the current sense resistor and the ISNS pin. A resistor with a value between 1 k $\Omega$  and 5 k $\Omega$  is selected, and a capacitor value is calculated by Equation 51.

$$C_{\mathsf{IFLT}} = \frac{0.1 \times \mathsf{D}_{\mathsf{MIN}}}{f_{\mathsf{SW}} \times \mathsf{R}_{\mathsf{IFLT}}} = \frac{0.1 \times 0.428}{600 \,\mathsf{kHz} \times 1 \mathsf{k}\Omega} = 71 \mathsf{pF} \tag{51}$$

For a 1-k $\Omega$  filter resistor, 71 pF is calculated and a 100-pF capacitor is selected.

#### **Switching MOSFET Selection**

The TPS40210 drives a ground referenced N-channel FET. The R<sub>DS(on)</sub> and gate charge are estimated based on the desired efficiency target.

$$P_{DISS(total)} \approx P_{OUT} \times \left(\frac{1}{\eta} - 1\right) = V_{OUT} \times I_{OUT} \times \left(\frac{1}{\eta} - 1\right) = 24 \text{ V} \times 2 \text{ A} \times \left(\frac{1}{0.95} - 1\right) = 2.526 \text{ W}$$

$$(52)$$

For a target of 95% efficiency with a 24-V input voltage at 2 A, maximum power dissipation is limited to 2.526 W. The main power dissipating devices are the MOSFET, inductor, diode, current sense resistor and the integrated circuit, the TPS40210.

$$P_{\text{FET}} < P_{\text{DISS(total)}} - P_{\text{L}} - P_{\text{D}} - P_{\text{Risns}} - V_{\text{IN(max)}} \times I_{\text{VDD}}$$
(53)

This leaves 740 mW of power dissipation for the MOSFET. This can likely cause an SO-8 MOSFET to get too hot, so power dissipation is limited to 500 mW. Allowing half for conduction and half for switching losses, we can determine a target  $R_{DS(on)}$  and  $Q_{GS}$  for the MOSFET by Equation 54 and Equation 55.

$$Q_{GS} < \frac{3 \times P_{FET} \times I_{DRIVE}}{2 \times V_{OUT} \times I_{OUT} \times f_{SW}} = \frac{3 \times 0.50 \,\text{W} \times 0.50 \,\text{A}}{2 \times 24 \,\text{V} \times 2 \,\text{A} \times 600 \,\text{kHz}} = 13.0 \,\text{nC}$$
(54)

A target MOSFET gate-to-source charge of less than 13.0 nC is calculated to limit the switching losses to less than 250 mW.

30

$$R_{DS(on)} < \frac{P_{FET}}{2 \times (I_{RMS})^2 \times D} = \frac{0.50 \,\text{W}}{2 \times 6.13^2 \times 0.674} = 9.8 \,\text{m}\Omega \tag{55}$$

A target MOSFET  $R_{DS(on)}$  of 9.8 m $\Omega$  is calculated to limit the conduction losses to less than 250 mW. Reviewing 30-V and 40-V MOSFETs, an Si4386DY 9-m $\Omega$  MOSFET is selected. A gate resistor was added per Equation 30. The maximum gate charge at Vgs = 8 V for the Si4386DY is 33.2 nC, this implies RG = 3.3  $\Omega$ .

#### **Feedback Divider Resistors**

The primary feedback divider resistor ( $R_{FB}$ ) from  $V_{OUT}$  to FB should be selected between 10-k $\Omega$  and 100-k $\Omega$  to maintain a balance between power dissipation and noise sensitivity. For a 24-V output a high feedback resistance is desirable to limit power dissipation so  $R_{FB}$  = 51.1 k $\Omega$  is selected.

$$R_{BIAS} = \frac{V_{FB} \times R_{FB}}{V_{OUT} - V_{FB}} = \frac{0.700 \, \text{V} \times 51.1 \text{k}\Omega}{24 \, \text{V} - 0.700 \, \text{V}} = 1.53 \, \text{k}\Omega \tag{56}$$

 $R_{BIAS} = 1.50 \text{ k}\Omega$  is selected.

## **Error Amplifier Compensation**

While current mode control typically requires only Type II compensation, it is desirable to layout for Type III compensation to increase flexibility during design and development.

Current mode control boost converters have higher gain with higher output impedance, so it is necessary to calculate the control loop gain at the maximum output impedance, estimated by Equation 57.

$$R_{OUT(max)} = \frac{V_{OUT}}{I_{OUT(min)}} = \frac{24 \text{ V}}{0.1 \text{A}} = 240 \Omega$$
 (57)

The transconductance of the TPS40210 current mode control can be estimated by Equation 58.

$$g_{M} = \frac{0.13 \times \sqrt{L \times \frac{f_{SW}}{R_{OUT}}}}{\left(R_{ISNS}\right)^{2} \times \left(120 \times R_{ISNS} + L \times f_{SW}\right)} = \frac{0.13 \times \sqrt{10 \,\mu\text{H} \times \frac{600 \,\text{kHz}}{240 \,\Omega}}}{\left(12m\Omega\right)^{2} \times \left(120 \times 12m\Omega + 10 \,\mu\text{H} \times 600 \,\text{kHz}\right)} = 19.1 \,\text{A/V}$$
(58)

The maximum output impedance Z<sub>OUT</sub>, can be estimated by Equation 59.

$$|Z_{OUT}(f)| = R_{OUT} \times \sqrt{\frac{\left(1 + \left(2\pi \times f \times R_{ESR} \times C_{OUT}\right)^{2}\right)}{1 + \left(\left(R_{OUT}\right)^{2} + 2 \times R_{OUT} \times R_{ESR} + \left(R_{ESR}\right)^{2}\right) \times \left(2\pi \times f \times C_{OUT}\right)^{2}}}$$

$$|Z_{OUT}(f_{CO})| = 240\Omega \times \sqrt{\frac{\left(1 + \left(2\pi \times 20 \, \text{kHz} \times 60 \, \text{m}\Omega \times 39.8 \, \mu\text{F}\right)^{2}\right)}{1 + \left(\left(240\Omega\right)^{2} + 2 \times 240\Omega \times 60 \, \text{m}\Omega + \left(60 \, \text{m}\Omega\right)^{2}\right) \times \left(2\pi \times 20 \, \text{kHz} \times 39.8 \, \mu\text{F}\right)^{2}}} = 0.146\Omega$$
(60)

The modulator gain at the desired cross-over can be estimated by Equation 61.

$$|K_{CO}| = g_{M} \times |Z_{OUT}(f_{CO})| = 19.1 \text{ A} / \times 0.146 \Omega = 2.80$$
 (61)

The feedback compensation network needs to be designed to provide an inverse gain at the cross-over frequency for unit loop gain. This sets the compensation mid-band gain at a value calculated in Equation 62.

$$K_{COMP} = \frac{1}{|K_{CO}|} = \frac{1}{2.80} = 0.356$$
 (62)

To set the mid-band gain of the error amplifier to K<sub>COMP</sub> use Equation 63.

$$R4 = R7 \times K_{COMP} = \frac{R7}{|K_{CO}|} = \frac{51.1 \text{k}\Omega}{2.80} = 18.2 \text{k}\Omega$$
(63)

 $R4 = 18.7 \text{ k}\Omega$  selected.

Place the zero at 10th the desired cross-over frequency.

$$C2 = \frac{10}{2\pi \times f_{L} \times R4} = \frac{10}{2\pi \times 30 \,\text{kHz} \times 18.7 \,\text{k}\Omega} = 2837 \,\text{pF}$$
 (64)

C2 = 2200 pF selected.

Place a high-frequency pole at about five times the desired cross-over frequency and less than one-half the unity gain bandwidth of the error amplifier:

$$C4 \approx \frac{1}{10\pi \times f_{L} \times R4} = \frac{1}{10\pi \times 30 \,\text{kHz} \times 18.7 \,\text{k}\Omega} = 56.74 \,\text{pF}$$
(65)

$$C4 > \frac{1}{\pi \times GBW \times R4} = \frac{1}{\pi \times 1.5MHz \times 18.7k\Omega} = 11.35pF$$
(66)

C4 = 47 pF selected.

#### **R-C Oscillator**

The R-C oscillator calculation as shown in Equation 5 substitutes 100 for  $C_T$  and 600 for  $f_{SW}$ . For a 600-kHz switching frequency, a 100-pF capacitor is selected and a 262-k $\Omega$  resistor is calculated (261 k $\Omega$  selected).

#### **Soft-Start Capacitor**

Because VDD > 8 V, the soft-start capacitor is selected by using Equation 67 to calculate the value.

$$C_{SS} = 20 \times T_{SS} \times 10^{-6} \tag{67}$$

For  $T_{SS}$  = 12 ms,  $C_{SS}$  = 240 nF, a 220-nF capacitor selected.

## **Regulator Bypass**

A regulator bypass capacitor of 1.0- $\mu F$  is selected per the recommendation.

<sup>(1)</sup> Status: For more details on status, see our product life cycle.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

<sup>(2)</sup> Material type: When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

<sup>(3)</sup> RoHS values: Yes, No. RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

<sup>(4)</sup> Lead finish/Ball material: Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

<sup>(5)</sup> MSL rating/Peak reflow: The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

<sup>(6)</sup> Part marking: There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.
