

SBAS460A - MAY 2009 - REVISED DECEMBER 2009

# Octal, 14-Bit, Low-Power, High-Voltage Output, Serial Input DIGITAL-TO-ANALOG CONVERTER

Check for Samples: DAC8218

### **FEATURES**

Bipolar Output: ±2V to ±16.5V
Unipolar Output: 0V to +33V

• 14-Bit Resolution

• Low Power: 14.4mW/Ch (Bipolar Supply)

Relative Accuracy: 1 LSB Max
 Low Zero/Full-Scale Error

- Before User Calibration: ±2.5 LSB Max

After User Calibration: ±1 LSB

• Flexible System Calibration

Low Glitch: 4nV-sSettling Time: 15µs

Channel Monitor OutputProgrammable Gain: x4/x6

• Programmable Offset

SPI™: Up to 50MHz, 1.8V/3V/5V Logic

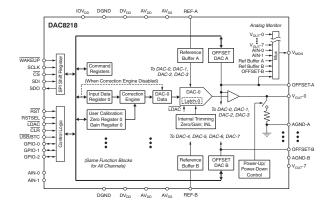

• Schmitt Trigger Inputs

Daisy-Chain with Sleep Mode Enhancement

 Packages: QFN-48 (7x7mm), TQFP-64 (10x10mm)

## **APPLICATIONS**

- Automatic Test Equipment
- PLC and Industrial Process Control
- Communications

### DESCRIPTION

The DAC8218 is a low-power, octal, 14-bit digital-to-analog converter (DAC). With a 5V reference, the output can either be a bipolar ±15V voltage when operating from dual ±15.5V (or higher) power supplies, or a unipolar 0V to +30V voltage when operating from a +30.5V (or higher) power supply. With a 5.5V reference, the output can either be a bipolar ±16.5V voltage when operating from dual ±17V (or higher) power supplies, or a unipolar 0V to +33V voltage when operating from a +33.5V (or higher) power supply. This DAC provides low-power operation, good linearity, and low glitch over the specified temperature range of -40°C to +105°C. This device is trimmed in manufacturing and has very low zero-code and gain error. In addition, system level calibration can be performed to achieve ±1 LSB bipolar zero/full-scale error with bipolar supplies, or ±1 LSB zero code/full-scale error with a unipolar supply, over the entire signal chain. The output range can be offset by using the DAC offset register.

The DAC8218 features a standard, high-speed serial peripheral interface (SPI) that operates at up to 50MHz and is 1.8V, 3V, and 5V logic compatible, to communicate with a DSP or microprocessor. The input data of the device are double-buffered. An asynchronous load input (LDAC) transfers data from the DAC data register to the DAC latch. The asynchronous CLR input sets the output of all eight DACs to AGND. The V<sub>MON</sub> pin is a monitor output that connects to the individual analog outputs, the offset DAC, the reference buffer outputs, and two external inputs through a multiplexer (mux).

The DAC8218 is pin-to-pin and function-compatible with the DAC8718 (16-bit) and the DAC7718 (12-bit).

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

DSP is a trademark of Texas Instruments. SPI, QSPI are trademarks of Motorola Inc. Microwire is a trademark of National Semiconductor. All other trademarks are the property of their respective owners.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

| Full-scale error TC               | Gain = 4 or 6, code = 3FFFh  |     | ±0.5 | ±3   | ppm FSR/°C |
| DC crosstalk <sup>(3)</sup>       | Measured channel at code = 2000h, full-scale change on any other channel |     | 0.05 |      | LSB        |

<sup>(1)</sup> Offset DAC A and Offset DAC B are trimmed in manufacturing to minimize the error for symmetrical output. The default value may vary no more than ±3 LSB from the nominal number listed in Table 7. The Offset DAC pins are not intended to drive an external load, and must not be connected during dual-supply operation.

Copyright © 2009, Texas Instruments Incorporated

<sup>(2)</sup> Gain = 4 and TC specified by design and characterization.

<sup>(3)</sup> The DAC outputs are buffered by op amps that share common AV<sub>DD</sub> and AV<sub>SS</sub> power supplies. DC crosstalk indicates how much dc change in one or more channel outputs may occur when the dc load current changes in one channel (because of an update). With high-impedance loads, the effect is virtually immeasurable. Multiple AV<sub>DD</sub> and AV<sub>SS</sub> terminals are provided to minimize dc crosstalk.

| Power-supply rejection <sup>(14)</sup> | AV <sub>DD</sub> = ±15.5V to ±16.5V  |      | 0.05 |      | LSB                |

- (4) Specified by design.
- (5) The analog output range of V<sub>OUT</sub>-0 to V<sub>OUT</sub>-7 is equal to (6 x V<sub>REF</sub> 5 x OUTPUT\_OFFSET\_DAC) for gain = 6. The maximum value of the analog output must not be greater than (AV<sub>DD</sub> 0.5V), and the minimum value must not be less than (AV<sub>SS</sub> + 0.5V). All specifications are for a ±16.5V power supply and a ±15V output, unless otherwise noted.
- (6) When the output current is greater than the specification, the current is clamped at the specified maximum value.
- (7) Slew rate is measured from 10% to 90% of the transition when the output changes from 0 to full-scale.
- (8) Power-on delay is defined as the time from when the supply voltages reach the specified conditions to when  $\overline{\text{CS}}$  goes low, for valid digital communication.
- (9) Digital-to-analog glitch is defined as the amount of energy injected into the analog output at the major code transition. It is specified as the area of the glitch in nV-s. It is measured by toggling the DAC register data between 1FFFh and 2000h in straight binary format.
- (10) Channel-to-channel isolation refers to the ratio of the signal amplitude at the output of one DAC channel to the amplitude of the sinusoidal signal on the reference input of another DAC channel. It is expressed in dB and measured at midscale.
- (11) DAC-to-DAC crosstalk is the glitch impulse that appears at the output of one DAC as a result of both the full-scale digital code and subsequent analog output change at another DAC. It is measured with LDAC tied low and expressed in nV-s.
- (12) Digital crosstalk is the glitch impulse transferred to the output of one converter as a result of a full-scale code change in the DAC input register of another converter. It is measured when the DAC output is not updated, and is expressed in nV-s.
- (13) Digital feedthrough is the glitch impulse injected to the output of a DAC as a result of a digital code change in the DAC input register of the same DAC. It is measured with the full-scale digital code change without updating the DAC output, and is expressed in nV-s.
- (14) The output must not be greater than  $(AV_{DD} 0.5V)$  and not less than  $(AV_{SS} + 0.5V)$ .

<sup>(15)</sup> Specified by design.

<sup>(16)</sup> Offset DAC A and Offset DAC B are trimmed in manufacturing to minimize the error for symmetrical output. The default value may vary no more than ±3 LSB from the nominal number listed in Table 7. The Offset DAC pins are not intended to drive an external load, and must not be connected during dual-supply operation.

<sup>(17)</sup>  $8k\Omega$  when  $V_{MON}$  is connected to Reference Buffer A or B, and  $4k\Omega$  when  $V_{MON}$  is connected to Offset DAC-A or -B.

<sup>(18)</sup> Reference input voltage ≤ DV<sub>DD</sub>.

- (1) Gain = 4 and TC specified by design and characterization.
- (2) The DAC outputs are buffered by op amps that share common AV<sub>DD</sub> and AV<sub>SS</sub> power supplies. DC crosstalk indicates how much dc change in one or more channel outputs may occur when the dc load current changes in one channel (because of an update). With high-impedance loads, the effect is virtually immeasurable. Multiple AV<sub>DD</sub> and AV<sub>SS</sub> terminals are provided to minimize dc crosstalk.
- (4) The analog output range of V<sub>OUT</sub>-0 to V<sub>OUT</sub>-7 is equal to (6 × V<sub>REF</sub>) for gain = 6. The maximum value of the analog output must not be greater than (AV<sub>DD</sub> 0.5V). All specifications are for a +32V power supply and a 0V to +30V output, unless otherwise noted.
- (5) When the output current is greater than the specification, the current is clamped at the specified maximum value.
- (6) Slew rate is measured from 10% to 90% of the transition when the output changes from 0 to full-scale.
- (7) Power-on delay is defined as the time from when the supply voltages reach the specified conditions to when  $\overline{\text{CS}}$  goes low, for valid digital communication.
- (8) Digital-to-analog glitch is defined as the amount of energy injected into the analog output at the major code transition. It is specified as the area of the glitch in nV-s. It is measured by toggling the DAC register data between 1FFFh and 2000h in straight binary format.
- (9) Channel-to-channel isolation refers to the ratio of the signal amplitude at the output of one DAC channel to the amplitude of the sinusoidal signal on the reference input of another DAC channel. It is expressed in dB and measured at midscale.

<sup>(10)</sup> DAC-to-DAC crosstalk is the glitch impulse that appears at the output of one DAC as a result of both the full-scale digital code and subsequent analog output change at another DAC. It is measured with LDAC tied low and expressed in nV-s.

<sup>(11)</sup> Digital crosstalk is the glitch impulse transferred to the output of one converter as a result of a full-scale code change in the DAC input register of another converter. It is measured when the DAC output is not updated, and is expressed in nV-s.

<sup>(12)</sup> Digital feedthrough is the glitch impulse injected to the output of a DAC as a result of a digital code change in the DAC input register of the same DAC. It is measured with the full-scale digital code change without updating the DAC output, and is expressed in nV-s.

<sup>(13)</sup> The analog output must not be greater than  $(AV_{DD} - 0.5V)$ . (14)  $8k\Omega$  when  $V_{MON}$  is connected to Reference Buffer A or B, and  $4k\Omega$  when  $V_{MON}$  is connected to Offset DAC-A or -B.

<sup>(15)</sup> Specified by design.

## **FUNCTIONAL BLOCK DIAGRAM**

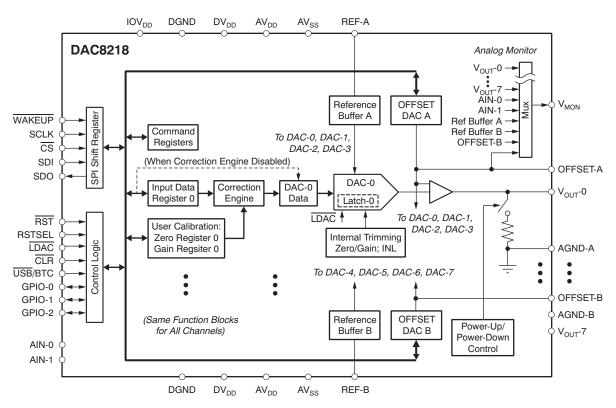

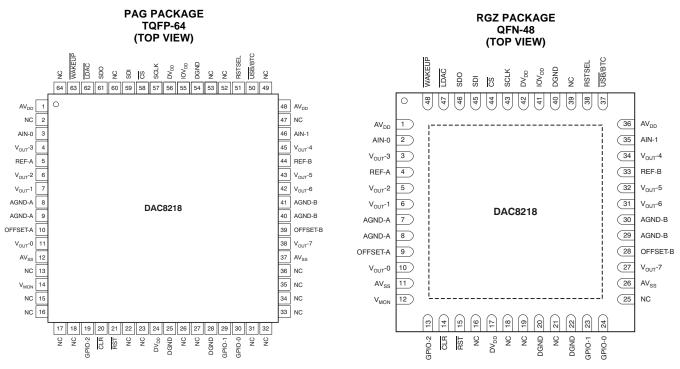

Figure 1. Functional Block Diagram

### PIN CONFIGURATIONS

(1) The thermal pad is internally connected to the substrate. This pad can be connected to AV<sub>SS</sub> or left floating. Keep the thermal pad separate from the digital ground, if possible.

### PIN DESCRIPTIONS

| PIN                 | PIN    | NO.     |     |  |
|---------------------|--------|---------|-----|--|
| NAME                | QFN-48 | TQFP-64 | I/O | DESCRIPTION  |
| $AV_{DD}$           | 1      | 1       | I   | Positive analog power supply   |
| AIN-0               | 2      | 3       | I   | Auxiliary analog input 0, directly routed to the analog mux  |
| V <sub>OUT</sub> -3 | 3      | 4       | 0   | DAC-3 output   |
| REF-A               | 4      | 5       | I   | Group A <sup>(1)</sup> reference input   |
| V <sub>OUT</sub> -2 | 5      | 6       | 0   | DAC-2 output   |
| V <sub>OUT</sub> -1 | 6      | 7       | 0   | DAC-1 output   |
| AGND-A              | 7      | 8       | I   | Group A analog ground and the ground of REF-A. This pin must be tied to AGND-B and DGND.   |
| AGND-A              | 8      | 9       | 1   | Group A analog ground and the ground of REF-A. This pin must be tied to AGND-B and DGND.   |
| OFFSET-A            | 9      | 10      | 0   | OFFSET DAC-A analog output. Must be connected to AGND-A during single power-supply operation (AV <sub>SS</sub> = 0V). This pin is not intended to drive an external load.  |
| V <sub>OUT</sub> -0 | 10     | 11      | 0   | DAC-0 output   |
| AV <sub>SS</sub>    | 11     | 12      | 1   | Negative analog power supply   |
| V <sub>MON</sub>    | 12     | 14      | 0   | Analog monitor output. This pin is either in Hi-Z status, connected to one of the eight DAC outputs, reference buffer outputs, offset DAC outputs, or one of the auxiliary analog inputs, depending on the content of the Monitor Register. See the Monitor Register, Table 12, for details.   |
| GPIO-2              | 13     | 19      | I/O | General-purpose digital input/output 2. This pin is a bidirectional digital input/output, open-drain and requires an external pull-up resistor. See the <i>GPIO Pins</i> section for details.  |
| CLR                 | 14     | 20      | I   | Clear input, level triggered. When the $\overline{\text{CLR}}$ pin is logic '0', all V <sub>OUT</sub> -X pins connect to AGND-x through switches and internal low-impedance. When the $\overline{\text{CLR}}$ pin is logic '1', all V <sub>OUT</sub> -X pins connect to the amplifier outputs. |
| RST                 | 15     | 21      | I   | Reset input (active low). Logic low on this pin resets the DAC registers and DACs to the values defined by the RSTSEL pin. CS must be logic high when RST is active.   |

(1) Group A consists of DAC-0, DAC-1, DAC-2, and DAC-3. Group B consists of DAC-4, DAC-5, DAC-6, and DAC-7.

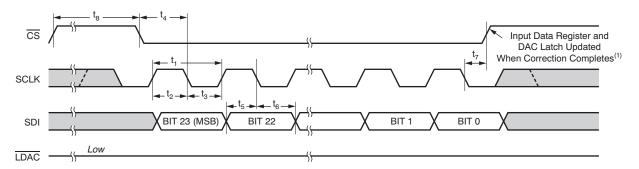

# PIN DESCRIPTIONS (continued)

| DIN                 | PIN PIN NO.               |  |     |  |  |  |  |  |  |

| $IOV_{DD}$          | 41                        | 55   | I   | Interface power  |  |  |  |  |  |
| $DV_DD$             | 42                        | 56   | I   | Digital power supply   |  |  |  |  |  |
| SCLK                | 43                        | 57   | I   | SPI bus serial clock input   |  |  |  |  |  |
| <del>CS</del>       | 44                        | 58   | I   | SPI bus chip select input (active low). Data are not clocked into SDI unless $\overline{CS}$ is low. When $\overline{CS}$ is high, SDO is in a high-impedance state and the SCLK and SDI signals are blocked from the device.  |  |  |  |  |  |
| SDI                 | 45                        | 59   | I   | SPI bus serial data input  |  |  |  |  |  |
| SDO                 | 46                        | 61   | 0   | SPI bus serial data output.  When the DSDO bit = '0', the SDO pin works as an output in normal operation.  When the DSDO bit = '1', SDO is always in a Hi-Z state, regardless of the CS pin status. Refer to the <i>Timing Diagrams</i> section for details.   |  |  |  |  |  |
| LDAC                | 47                        | 62   | I   | Load DAC latch control input (active low). When \$\overline{LDAC}\$ is low, the DAC latch is transparent and the contents of the DAC Data Register are transferred to it. The DAC output changes to the corresponding level simultaneously when the DAC latch is updated. See the \$Updating the DAC Outputs\$ section for details. If asynchronous mode is desired, \$\overline{LDAC}\$ must be permanently tied low before power is applied to the device. If synchronous mode is desired, \$\overline{LDAC}\$ must be logic high during power-on. |  |  |  |  |  |
| WAKEUP              | 48                        | 63   | I   | Wake-up input (active low). Restores the SPI from sleep to normal operation. See the <i>Daisy-Chain Operation</i> section for details.   |  |  |  |  |  |

## **TIMING DIAGRAMS**

Case 1: Standalone mode: Update without LDAC pin; LDAC pin tied to logic low.

NOTE: (1) If the correction engine is off, the DAC latch is reloaded immediately after the DAC Data Register is updated.

Case 2: Standalone mode: Update with LDAC pin.

NOTE: (2) The DAC latch is updated when  $\overline{\text{LDAC}}$  goes low, as long as the timing requirement of  $t_g$  is satisfied.

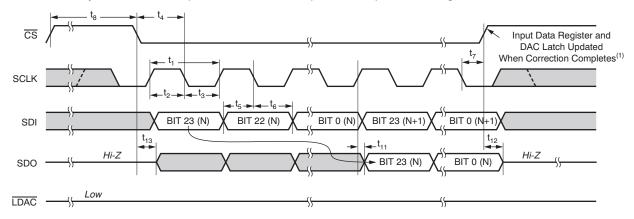

Figure 2. SPI Timing for Standalone Mode

Copyright © 2009, Texas Instruments Incorporated

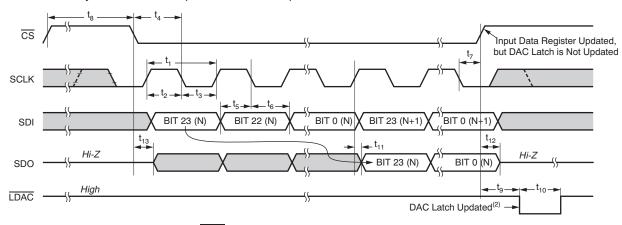

# **TIMING DIAGRAMS (continued)**

Case 3: Daisy-Chain Mode: Update without LDAC pin; LDAC pin tied to logic low.

NOTE: (1) If the correction engine is off, the DAC latch is reloaded immediately after the DAC Data Register is updated.

# Case 4: Daisy-Chain Mode: Update with LDAC pin.

NOTE: (2) The DAC latch is updated when  $\overline{\text{LDAC}}$  goes low. The proper data are loaded if the  $t_9$  timing requirement is satisfied. Otherwise, invalid data are loaded.

## Case 5: Daisy-Chain Mode: Sleeping.

### THEORY OF OPERATION

### **GENERAL DESCRIPTION**

The DAC8218 contains eight DAC channels and eight output amplifiers in a single package. Each channel consists of a resistor-string DAC followed by an output buffer amplifier. The resistor-string section is simply a string of resistors, each with a value of R, from REF-x to AGND, as shown in Figure 97. This type of architecture provides DAC monotonicity. The 14-bit binary digital code loaded to the DAC latch determines at which node on the string the voltage is tapped off before being fed into the output amplifier. The output amplifier multiplies the DAC output voltage by a gain of six or four. Using a gain of 6 and power supplies allowing for at least 0.5V headroom, the output span is 9V with a 1.5V reference, 18V with a 3V reference, and 30V with a 5V reference.

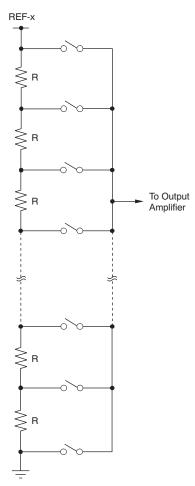

Figure 97. Resistor String

## **CHANNEL GROUPS**

The eight DAC channels and two Offset DACs are arranged into two groups (A and B) with four channels and one Offset DAC per group. Group A consists of DAC-0, DAC-1, DAC-2, DAC-3, and Offset DAC-A. Group B consists of DAC-4, DAC-5, DAC-6, DAC-7, and Offset DAC-B. Group A derives its reference voltage from REF-A, and Group B derives its reference voltage from REF-B.

### **USER-CALIBRATION FOR ZERO-CODE ERROR AND GAIN ERROR**

The DAC8218 implements a digital user-calibration function that allows for trimming gain and zero errors on the entire signal chain. This function can eliminate the need for external adjustment circuits. Each DAC channel has a Zero Register and Gain Register. Using the correction engine, the data from the Input Data Register are operated on by a digital adder and multiplier controlled by the contents of the Zero and Gain registers, respectively. The calibrated DAC data are then stored in the DAC Data Register where they are finally transferred into the DAC latch and set the DAC output. Each time the data are written to the Input Data Register (or to the Gain or Zero registers), the data in the Input Data Register are corrected, and the results automatically transferred to the DAC Data Register.

The range of the gain adjustment coefficient is 0.5 to 1.5. The range of the zero adjustment is -8192 LSB to +8191 LSB, or  $\pm 50\%$  of full scale.

There is only one correction engine in the DAC8218, which is shared among all channels.

If the user-calibration function is not needed, the correction engine can be turned off. Setting the SCE bit in the Configuration Register to '0' turns off the correction engine. Setting SCE to '1' enables the correction engine. When SCE = '0', the data are directly transferred to the DAC Data Register. In this case, writing to the Gain Register or Zero Register updates the Gain and Zero registers but does not start a math engine calculation. Reading these registers returns the written values.

# ANALOG OUTPUTS ( $V_{OUT}$ -0 to $V_{OUT}$ -7, with reference to the ground of REF-x)

When the correction engine is off (SCE = '0'):

$$V_{OUT} = V_{REF} \times Gain \times \left(\frac{INPUT\_CODE}{16384}\right) - V_{REF} \times (Gain - 1) \times \left(\frac{OFFSETDAC\_CODE}{16384}\right)$$
(1)

When the correction engine is on (SCE = '1'):

$$V_{OUT} = V_{REF} \times Gain \times \left(\frac{DAC\_DATA\_CODE}{16384}\right) - V_{REF} \times (Gain - 1) \times \left(\frac{OFFSETDAC\_CODE}{16384}\right)$$
(2)

Where:

$$DAC\_DATA\_CODE = \left(\frac{INPUT\_CODE \times (USER\_GAIN + 2^{13})}{2^{14}}\right) + USER\_ZERO$$

Gain = the DAC gain defined by the GAIN bit in the Configuration Register.

INPUT CODE = data written into the Input Data Register (SCE = '1') or DAC Data Register (SCE = '0').

OFFSETDAC\_CODE = the data written into the Offset DAC Register.

USER\_GAIN = the code of the Gain Register.

USER ZERO = the code of the Zero Register.

For single-supply operation, the OFFSET-A pin must be connected to the AGND-A pin and the OFFSET-B pin must be connected to the AGND-B pin through low-impedance connections (see the *Layout* section for details). Offset DAC-A and Offset DAC-B are in a power-down state.

For dual-supply operation, the OFFSET-A and OFFSET-B default codes for a gain of 6 are 9830 with a ±3 LSB variation, depending on the linearity of the Offset DACs. The default code for a gain of 4 is 10923 with a ±3 LSB variation. The default codes of OFFSET-A and OFFSET-B are independently factory trimmed for both gains of 6 and 4.

The power-on default value of the Gain Register is 8192, and the default value of the Zero Register is '0'. The DAC input registers are set to a default value of 0000h.

Note that the maximum output voltage must not be greater than  $(AV_{DD} - 0.5V)$  and the minimum output voltage must not be less than  $(AV_{SS} + 0.5V)$ ; otherwise, the output may be saturated.

Product Folder Link(s): DAC8218

#### **INPUT DATA FORMAT**

The USB/BTC pin defines the input data format and the Offset DAC format. When this pin is connected to DGND, the Input DAC data and Offset DAC data are straight binary, as shown in Table 1 and Table 3. When this pin is connected to IOV<sub>DD</sub>, the Input DAC data and Offset DAC data are in twos complement format, as shown in Table 2 and Table 4.

Table 1. Bipolar Output vs Straight Binary Code Using Dual Power Supplies with Gain = 6

The data written to the Gain Register are always in straight binary, data to the Zero Register are in twos complement, and data to all other control registers are as specified in the definitions, regardless of the USB/BTC pin status.

In reading operation, the read-back data are in the same format as written.

#### OFFSET DACS

There are two 14-bit Offset DACs: one for Group A, and one for Group B. The Offset DACs allow the entire output curve of the associated DAC groups to be shifted by introducing a programmable offset. This offset allows for asymmetric bipolar operation of the DACs or unipolar operation with bipolar supplies. Thus, subject to the limitations of headroom, it is possible to set the output range of Group A and/or Group B to be unipolar positive, unipolar negative, symmetrical bipolar, or asymmetrical bipolar, as shown in Table 5 and Table 6. Increasing the digital input codes for the offset DAC shifts the outputs of the associated channels in the negative direction. The default codes for the Offset DACs in the DAC8218 are factory trimmed to provide optimal offset and gain performance for the default output range and span of symmetric bipolar operation. When the output range is adjusted by changing the value of the Offset DAC, an extra offset is introduced as a result of the linearity and offset errors of the Offset DAC. Therefore, the actual shift in the output span may vary slightly from the ideal calculations. For optimal offset and gain performance in the default symmetric bipolar operation, the Offset DAC input codes should not be changed from the default power-on values. The maximum allowable offset depends on the reference and the power supply. If INPUT\_CODE from Equation 1 or DAC\_DATA\_CODE from Equation 2 is set to 0, then these equations simplify to Equation 3:

$$V_{OUT} = -V_{REF} \times (Gain - 1) \times \left( \frac{OFFSETDAC\_CODE}{16384} \right)$$
 (3)

This equation shows the transfer function of the Offset DAC to the output of the DAC channels. In any case, the analog output must not go beyond the specified range shown in the *Analog Outputs* section. After power-on or reset, the Offset DAC is set to the value defined by the selected data format and the selected analog output voltage. If the DAC gain setting is changed, the offset DAC code is reset to the default value corresponding to the new DAC gain setting. Refer to the *Power-On Reset* and *Hardware Reset* sections for details.

For single-supply operation (AV $_{SS}$  = 0V), the Offset DAC is turned off, and the output amplifier is in a Hi-Z state. The OFFSET-x pin must be connected to the AGND-x pin through a low-impedance connection (see the *Layout* section for details). For dual-supply operation, this pin provides the output of the Offset DAC. The OFFSET-x pin is not intended to drive an external load. See Figure 98 for the internal Offset DAC and output amplifier configuration.

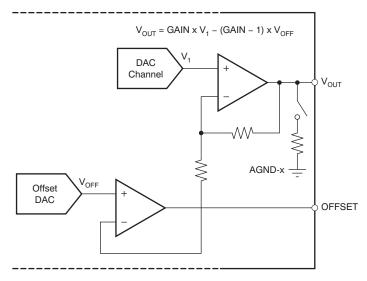

Figure 98. Output Amplifier and Offset DAC

# **OUTPUT AMPLIFIERS**

The output amplifiers can swing to 0.5V below the positive supply and 0.5V above the negative supply. This condition limits how much the output can be offset for a given reference voltage. The maximum range of the output for  $\pm 17V$  power and a  $\pm 5.5V$  reference is  $\pm 16.5V$  for gain  $\pm 6.5V$  for  $\pm 6.5V$  for gain  $\pm 6.5V$  for gain  $\pm 6.5V$  for  $\pm 6.5V$  fo

Each output amplifier is implemented with individual over-current protection. The amplifier is clamped at 8mA, even if the output current goes over 8mA.

# **GENERAL-PURPOSE INPUT/OUTPUT PINS (GPIO-0 to GPIO-2)**

The GPIO pins are general-purpose, bidirectional, digital input/outputs, as shown in Figure 99. When a GPIO pin acts as an output, the pin status is determined by the corresponding GPIO bit in the GPIO Register. The pin output is high-impedance when the GPIO bit is set to '1', and is logic low when the GPIO bit is cleared to '0'. Note that a pull-up resistor to  $IOV_{DD}$  is required when using a GPIO pin as an output. When a GPIO pin acts as an input, the digital value on the pin is acquired by reading the corresponding GPIO bit. After power-on reset, or any forced hardware or software reset, the GPIO bits are set to '1', and the GPIO pins are in a high-impedance state. If not used, the GPIO pins must be tied to either DGND or to  $IOV_{DD}$  through a pull-up resistor. Leaving the GPIO pins floating can cause high  $IOV_{DD}$  supply currents.

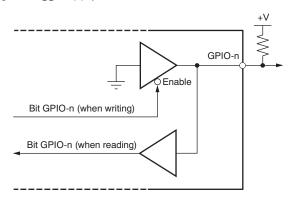

Figure 99. GPIO-n Pin

# ANALOG OUTPUT PIN (CLR)

The  $\overline{\text{CLR}}$  pin is an active low input that should be high for normal operation. When this pin is in logic '0', all  $V_{\text{OUT}}$  outputs connect to  $\overline{\text{AGND-x}}$  through internal 15k $\Omega$  resistors and are cleared to 0V, and the output buffer is in a Hi-Z state. While  $\overline{\text{CLR}}$  is low, all  $\overline{\text{LDAC}}$  pulses are ignored. When  $\overline{\text{CLR}}$  is taken high again while the  $\overline{\text{LDAC}}$  is high, the DAC outputs remain cleared until  $\overline{\text{LDAC}}$  is taken low. However, if  $\overline{\text{LDAC}}$  is tied low, taking  $\overline{\text{CLR}}$  back to high sets the DAC output to the level defined by the value of the DAC latch. The contents of the Zero Registers, Gain Registers, Input Data Registers, DAC Data Registers, and DAC latches are not affected by taking  $\overline{\text{CLR}}$  low.

#### **POWER-ON RESET**

The DAC8218 contains a power-on reset circuit that controls the output during power-on and power down. This feature is useful in applications where the known state of the DAC output during power-on is important. The Offset DAC Registers, DAC Data Registers, and DAC latches are loaded with the value defined by the RSTSEL pin, as shown in Table 7. The Gain Registers and Zero Registers are loaded with default values. The Input Data Register is reset to 0000h, independent of the RSTSEL state.

Table 7. Bipolar Output Reset Values for Dual Power-Supply Operation

| RSTSEL PIN        | USB/BTC PIN       | INPUT FORMAT    | VALUE OF DAC<br>DATA REGISTER<br>AND DAC LATCH | VALUE OF OFFSET<br>DAC REGISTER<br>FOR GAIN = 6 <sup>(1)</sup> | V <sub>out</sub> |
|-------------------|-------------------|-----------------|--|--|------------------|
| DGND              | DGND              | Straight Binary | 0000h  | 2666h  | -Full-Scale      |
| IOV <sub>DD</sub> | DGND              | Straight Binary | 2000h  | 2666h  | 0 V              |

| IOV <sub>DD</sub> | IOV <sub>DD</sub> | Twos Complement | 0000h  | 0666h  | 0 V              |

<sup>(1)</sup> Offset DAC A and Offset DAC B are trimmed in manufacturing to minimize the error for symmetrical output. The default value may vary no more than ±3 LSB from the nominal number listed in this table.

In single-supply operation, the Offset DAC is turned off and the output is unipolar. The power-on reset is defined as shown in Table 8.

Table 8. Unipolar Output Reset Values for Single Power-Supply Operation

| RSTSEL PIN        | USB/BTC PIN       | INPUT FORMAT    | VALUE OF DAC DATA<br>REGISTER AND DAC<br>LATCH | V <sub>out</sub> |
|-------------------|-------------------|-----------------|--|------------------|
| DGND              | DGND              | Straight Binary | 0000h  | 0 V              |

| IOV <sub>DD</sub> | IOV <sub>DD</sub> | Twos Complement | 0000h  | Midscale         |

#### HARDWARE RESET

When the  $\overline{RST}$  pin is low, the device is in hardware reset. All the analog outputs ( $V_{OUT}$ -0 to  $V_{OUT}$ -7), the DAC registers, and the DAC latches are set to the reset values defined by the RSTSEL pin as shown in Table 7 and Table 8. In addition, the Gain and Zero Registers are loaded with default values, communication is disabled, and the signals on  $\overline{CS}$  and SDI are ignored (note that SDO is in a high-impedance state). The Input Data Register is reset to 0000h, independent of the RSTSEL state. On the rising edge of  $\overline{RST}$ , the analog outputs ( $V_{OUT}$ -0 to  $V_{OUT}$ -7) maintain the reset value as defined by the RSTSEL pin until a new value is programmed. After  $\overline{RST}$  goes high, the serial interface returns to normal operation.  $\overline{CS}$  must be set to a logic high whenever  $\overline{RST}$  is used.

#### **UPDATING THE DAC OUTPUTS**

Depending on the status of both  $\overline{\text{CS}}$  and  $\overline{\text{LDAC}}$ , and after data have been transferred into the DAC Data registers, the DAC outputs can be updated either in asynchronous mode or synchronous mode. This update mode is established at power-on. If asynchronous mode is desired, the  $\overline{\text{LDAC}}$  pin must be permanently tied low before power is applied to the device. If synchronous mode is desired,  $\overline{\text{LDAC}}$  must be logic high before and during power-on.

The DAC8218 updates a DAC latch only if it has been accessed since the last time  $\overline{\text{LDAC}}$  was brought low or if the LD bit is set to '1', thereby eliminating any unnecessary glitch. Any DAC channels that were not accessed are not loaded again. When the DAC latch is updated, the corresponding output changes to the new level immediately.

#### **Asynchronous Mode**

In this mode, the  $\overline{\text{LDAC}}$  pin is set low at power-up. This action places the DAC8218 into Asynchronous mode, and the LD bit and LDAC signal are ignored. When the correction engine is off (SCE bit = '0'), the DAC Data Registers and DAC latches are updated immediately when  $\overline{\text{CS}}$  goes high. When the correction engine is on (SCE bit = '1'), each DAC latch is updated individually when the correction engine updates the corresponding DAC Data Register.

### **Synchronous Mode**

To use this mode, set  $\overline{\text{LDAC}}$  high before  $\overline{\text{CS}}$  goes low, and then take  $\overline{\text{LDAC}}$  low or set the LD bit to '1' after  $\overline{\text{CS}}$  goes high. If  $\overline{\text{LDAC}}$  goes low or if the LD bit is set to '1' when SCE = '0', all DAC latches are updated simultaneously. If  $\overline{\text{LDAC}}$  goes low or if the LD bit is set to '1' when SCE = '1', all DAC latches are updated simultaneously after the correction engine has updated the corresponding DAC register.

In this mode, when  $\overline{LDAC}$  stays high, the DAC latch is not updated; therefore, the DAC output does not change. The DAC latch is updated by taking  $\overline{LDAC}$  low (or by setting the LD bit in the Configuration Register to '1') any time after the delay of  $t_9$  from the rising edge of  $\overline{CS}$ . If the timing requirement of  $t_9$  is not satisfied, invalid data are loaded. Refer to the *Timing Diagrams* and the Configuration Register (Table 11) for details.

# MONITOR OUTPUT PIN (V<sub>MON</sub>)

The  $V_{MON}$  pin is the channel monitor output. It can be either high-impedance or monitor any one of the DAC outputs, auxiliary analog inputs, offset DAC outputs, or reference buffer outputs. The channel monitor function consists of an analog multiplexer addressed via the serial interface, allowing any channel output, reference buffer output, auxiliary analog inputs, or offset DAC output to be routed to the  $V_{MON}$  pin for monitoring using an external ADC. The monitor function is controlled by the Monitor Register, which allows the monitor output to be enabled or disabled. When disabled, the monitor output is high-impedance; therefore, several monitor outputs may be connected in parallel with only one enabled at a time.

Note that the multiplexer is implemented as a series of analog switches. Care should be taken to ensure the maximum current from the  $V_{MON}$  pin must not be greater than the given specification because this could conceivably cause a large amount of current to flow from the input of the multiplexer (that is, from  $V_{OUT}$ -X) to the output of the multiplexer ( $V_{MON}$ ). Refer to the *Monitor Register* section and Table 12 for more details.

#### **ANALOG INPUT PINS (AIN-0 and AIN-1)**

Pins AIN-0 and AIN-1 are two analog inputs that directly connect to the analog mux of the analog monitor output. When AIN-0 or AIN-1 is accessed, it is routed via the mux to the  $V_{MON}$  pin. Thus, one external ADC channel can monitor eight DACs plus two extra external analog signals, AIN-0 and AIN-1.

#### **POWER-DOWN MODE**

The DAC8218 is implemented with a power-down function to reduce power consumption. Either the entire device or each individual group can be put into power-down mode. If the proper power-down bit (PD-x) in the Configuration Register is set to '1', the individual group is put into power down mode. During power-down mode, the analog outputs ( $V_{OUT}$ -0 to  $V_{OUT}$ -7) connect to AGND-X through an internal 15k $\Omega$  resistor, and the output buffer is in Hi-Z status. When the entire device is in power-down, the bus interface remains active in order to continue communication and receive commands from the host controller, but all other circuits are powered down. The host controller can wake the device from power-down mode and return to normal operation by clearing the PD-x bit; it takes 200µs or less for recovery to complete.

#### **POWER-ON RESET SEQUENCING**

The DAC8218 permanently latches the status of some of the digital pins at power-on. These digital levels should be well-defined before or while the digital supply voltages are applied. Therefore, it is advised to have a pull up resistor to IOV<sub>DD</sub> for the digital initialization pins (LDAC, CLR, RST, CS, and RSTSEL) to ensure that these levels are set correctly while the digital supplies are raised.

For proper power-on initialization of the device,  $IOV_{DD}$  and the digital pins must be applied before or at the same time as  $DV_{DD}$ . If possible, it is preferred that  $IOV_{DD}$  and  $DV_{DD}$  can be connected together in order to simplify the supply sequencing requirements. Pull-up resistors should go to <u>either supply.  $AV_{DD}$  should be applied after the digital supplies ( $IOV_{DD}$  and  $DV_{DD}$ ) and digital initialization pins (IDAC, IDAC, I</u>

#### **SERIAL INTERFACE**

The DAC8218 is controlled over a versatile, three-wire serial interface that operates at clock rates of up to 50MHz and is compatible with SPI, QSPI™, Microwire™, and DSP™ standards.

#### **SPI Shift Register**

The SPI Shift Register is 24 bits wide. Data are loaded into the device MSB first as a 24-bit word under the control of the serial clock input, SCLK. The SPI Shift Register consists of a read/write bit, five register address bits, 14 data bits, and four reserve bits for future devices, as shown in Table 9. The falling edge of  $\overline{CS}$  starts the communication cycle. The data are latched into the SPI Shift Register on the falling edge of SCLK while  $\overline{CS}$  is low. When  $\overline{CS}$  is high, the SCLK and SDI signals are blocked and the SDO pin is in a high-impedance state. The contents of the SPI shifter register are decoded and transferred to the proper internal registers on the rising edge of  $\overline{CS}$ . The timing for this operation is shown in the *Timing Diagrams* section.

The serial interface works with both a continuous and non-continuous serial clock. A continuous SCLK source can only be used if  $\overline{CS}$  is held low for the correct number of clock cycles. In gated clock mode, a burst clock containing the exact number of clock cycles must be used and  $\overline{CS}$  must be taken high after the final clock in order to latch the data.

The serial interface requires  $\overline{CS}$  to be logic high during the power-on sequencing; therefore, it is advised to have a pullup resistor to  $IOV_{DD}$  on the  $\overline{CS}$  pin. Refer to the *Power-On Reset Sequencing* section for further details.

#### **Stand-Alone Operation**

The serial clock can be a continuous or a gated clock. The first falling edge of  $\overline{CS}$  starts the operation cycle. Exactly 24 falling clock edges must be applied before  $\overline{CS}$  is brought back high again. If  $\overline{CS}$  is brought high before the 24th falling SCLK edge, then the data written are not transferred into the internal registers. If more than 24 falling SCLK edges are applied before  $\overline{CS}$  is brought high, then the last 24 bits are used. The device internal registers are updated from the Shift Register on the rising edge of  $\overline{CS}$ . In order for another serial transfer to take place,  $\overline{CS}$  must be brought low again.

When the data have been transferred into the chosen register of the addressed DAC, all DAC latches and analog outputs can be updated by taking LDAC low.

#### **Daisy-Chain Operation**

For systems that contain more than one device, the SDO pin can be used to daisy-chain multiple devices together. Daisy-chain operation can be useful in system diagnostics and in reducing the number of serial interface lines. Note that before daisy-chain operation can begin, the SDO pin must be enabled by setting the SDO disable bit (DSDO) in the Configuration Register to '0'; this bit is cleared by default.

The DAC8218 provides two modes for daisy-chain operation: normal and sleep. The SLEEP bit in the SPI Mode register determines which mode is used.

In Normal mode (SLEEP bit = '0'), the data clocked into the SDI pin are transferred into the Shift Register. The first falling edge of  $\overline{CS}$  starts the operating cycle. SCLK is continuously applied to the SPI Shift Register when  $\overline{CS}$  is low. If more than 24 clock pulses are applied, the data ripple out of the Shift Register and appear on the SDO line. These data are clocked out on the rising edge of SCLK and are valid on the falling edge. By connecting the SDO pin of the first device to the SDI input of the next device in the chain, a multiple-device interface is constructed. Each device in the system requires 24 clock pulses. Therefore, the total number of clock cycles must equal  $24 \times N$ , where N is the total number of DAC8218s in the chain. When the serial transfer to all devices is complete,  $\overline{CS}$  is taken high. This action latches the data from the SPI Shift Registers to the device internal registers for each device in the daisy-chain, and prevents any further data from being clocked in. The serial clock can be a continuous or a gated clock. Note that a continuous SCLK source can only be used if  $\overline{CS}$  is held low for the correct number of clock cycles. For gated clock mode, a burst clock containing the exact number of clock cycles must be used and  $\overline{CS}$  must be taken high after the final clock in order to latch the data.

In Sleep mode (SLEEP bit = '1'), the <u>data</u> clocked into SDI are routed to the SDO pin directly; the Shift Register is bypassed. The first falling edge of <u>CS</u> starts the operating cycle. When SCLK is continuously applied with <u>CS</u> low, the data clocked into the SDI pin appear on the SDO pin almost immediately (with approximately a 5 ns delay; see the *Timing Diagrams* section); there is no 24 clock delay, as there is in normal operting mode. While in Sleep mode, no data bits are clocked into the Shift Register, and the device does not receive any new data or commands. Putting the device into Sleep mode eliminates the 24 clock delay from SDI to SDO caused by the

Shift Register, thus greatly speeding up the data transfer. For example, consider three DAC8218s (A, B, and C) in a daisy-chain configuration. The data from the SPI controller are transferred first to A, then to B, and finally to C. In normal daisy-chain operation, a total of 72 clocks are needed to transfer one word to C. However, if A and B are placed into Sleep mode, the first 24 data bits are directly transferred to C (through A and B); therefore, only 24 clocks are needed.

To wake the device up from sleep mode and return to normal operation, either one of following methods can be used:

- 1. Pull the WAKEUP pin low, which forces the SLEEP bit to '0' and returns the device to normal operating mode.
- 2. Use the W2 bit and the  $\overline{CS}$  pin.

When the W2 bit = '1', if  $\overline{CS}$  is applied with no more than one falling edge of SCLK, then the rising edge of  $\overline{CS}$  wakes the device from sleep mode back to normal operation. However, the device will not wake-up if more than one falling edge of SCLK exists while  $\overline{CS}$  is low.

#### **Read-Back Operation**

The READ command is used to start read-back operation. However, before read-back operation can be initiated, the SDO pin must be enabled by setting the DSDO bit in the Configuration Register to '0'; this bit is cleared by default. Read-back operation is then started by executing a READ command (R/W bit = '1', see Table 9). Bits A4 to A0 in the READ command select the register to be read. The remaining data in the command are *don't care* bits. During the next SPI operation, the data appearing on the SDO output are from the previously addressed register. For a read of a single register, a NOP command can be used to clock out the data from the selected register on SDO. Multiple registers can be read if multiple READ commands are issued. The readback diagram in Figure 100 shows the read-back sequence.

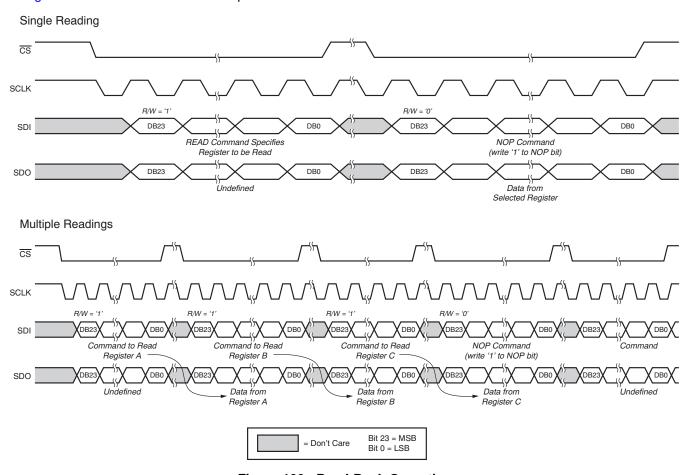

Figure 100. Read-Back Operation

#### **SPI SHIFT REGISTER**

The SPI Shift Register is 24 bits wide, as shown in Table 9. The register mapping is shown in Table 10; X = don't care—writing to it has no effect, reading it returns '0'.

#### **Table 9. Shift Register Format**

| MSB  |      |      |      |      |      |      |      |          |         |
|------|------|------|------|------|------|------|------|----------|---------|
| DB23 | DB22 | DB21 | DB20 | DB19 | DB18 | DB17 | DB16 | DB15:DB2 | DB1:DB0 |
| R/W  | Х    | Х    | A4   | A3   | A2   | A1   | A0   | DATA     | Х       |

**R/W** Indicates a read from or a write to the addressed register.

R/W = '0' sets a write operation and the data are written to the specified register.

R/W = '1' sets a read-back operation. Bits A4 to A0 select the register to be read. The remaining bits are *don't care* bits. During the next SPI operation, the data appearing on SDO pin are from the previously addressed register.

**A4:A0** Address bits that specify which register is accessed.

DATA 14 data bits

X = don't care—writing to this bit has no effect; reading the bit returns '0'.

Table 7 lists the default values for a dual power supply. Offset DAC A and Offset DAC B are trimmed in manufacturing to minimize the error for symmetrical output. The default value may vary no more than ±3 LSB from the nominal number listed in Table 7. For a single power supply, the Offset DACs are turned off.

(3) Writing to a reserved bit has no effect; reading the bit returns '0'.

#### **INTERNAL REGISTERS**

The DAC8218 internal registers consist of the Configuration Register, the Monitor Register, the DAC Input Data Registers, the Zero Registers, the DAC Data Registers, and the Gain Registers, and are described in the following section.

The Configuration Register specifies which actions are performed by the device. Table 11 shows the details.

Table 11. Configuration Register (Default = 2000h)

|       |        | DEFAULT |  |
|-------|--------|---------|--|
| BIT   | NAME   | VALUE   | DESCRIPTION  |
| D15   | A/B    | 1       | A/B bit.  When A/B = '0', reading DAC-x returns the value in the Input Data Register.  When A/B = '1', reading DAC-x returns the value in the DAC Data Register.  When the correction engine is enabled, the data returned from the Input Data Register is the original data written to the bus, and the value in the DAC Data Register is the corrected data.   |
| D14   | LD     | 0       | Synchronously update DACs bit. When $\overline{\text{LDAC}}$ is tied high, setting LD = '1' at any time after the write operation and the correction process complete synchronously updates all DAC latches with the content of the corresponding DAC Data Register, and sets $V_{\text{OUT}}$ to a new level. The DAC8218 updates the DAC latch only if it has been accessed since the last time $\overline{\text{LDAC}}$ was brought low or the LD bit was set to '1', thereby eliminating unnecessary glitch. Any DACs that were not accessed are not reloaded. After updating, the bit returns to '0'. When the correction engine is turned off, bit LD can be set to '1' any time after the writing operation is complete; the DAC latch is immediately updated when bit LD is set. When the $\overline{\text{LDAC}}$ pin is tied low, this bit is ignored. |
| D13   | RST    | 0       | Software reset bit. Set the RST bit to '1' to reset the device; functions the same as a hardware reset. After reset completes, the RST bit returns to '0'.   |
| D12   | PD-A   | 0       | Power-down bit for Group A (DAC-0, DAC-1, DAC-2, and DAC-3).  Setting the PD-A bit to '1' places Group A (DAC-0, DAC-1, DAC-2, and DAC-3) into power-down operation. All output buffers are in Hi-Z and all analog outputs (V <sub>OUT</sub> -X) connect to AGND-A through an internal 15-kΩ resistor. The interface is still active.  Setting the PD-A bit to '0' returns group A to normal operation.  |
| D11   | PD-B   | 0       | Power-down bit for Group B (DAC-4, DAC-5, DAC-6, and DAC-7).  Setting the PD-B bit to '1' places Group B (DAC-4, DAC-5, DAC-6, and DAC-7) into power-down operation. All output buffers are in Hi-Z and all analog outputs (V <sub>OUT</sub> -X) connect to AGND-B through an internal 15-kΩ resistor. The interface is still active.  Setting the PD-B bit to '0' returns group B to normal operation.  |
| D10   | SCE    | 0       | System-calibration enable bit.  Set the SCE bit to '1' to enable the correction engine. When the engine is enabled, the input data are adjusted by the correction engine according to the contents of the corresponding Gain Register and Zero Register. The results are transferred to the corresponding DAC Data Register, and finally loaded into the DAC latch, which sets the V <sub>OUT</sub> -x pin output level.  Set the SCE bit to '0' to turn off the correction engine. When the engine is turned off, the input data are transferred to the corresponding DAC Data Register immediately, and then loaded into the DAC latch, which sets the output voltage. Refer to the User Calibration for Zero-Code Error and Gain Error section for details.   |
| D9    | _      | 0       | Reserved. Writing to this bit has no effect; reading this bit returns '0'.   |
| D8    | GAIN-A | 0       | Gain bit for Group A (DAC-0, DAC-1, DAC-2, and DAC-3). Updating this bit to a new value automatically resets the Offset DAC-A Register to the factory-trimmed value for the new gain setting. Set the GAIN-A bit to '0' for an output span = 6 × REF-A. Set the GAIN-A bit to '1' for an output span = 4 × REF-A.  |
| D7    | GAIN-B | 0       | Gain bit for Group B (DAC-4, DAC-5, DAC-6, and DAC-7). Updating this bit to a new value automatically resets the Offset DAC-B Register to the factory-trimmed value for the new gain setting.  Set the GAIN-B bit to '0' for an output span = 6 x REF-B.  Set the GAIN-B bit to '1' for an output span = 4 x REF-B.  |
| D6    | DSDO   | 0       | Disable SDO bit. Set the DSDO bit to '0' to enable the SDO pin (default). The SDO pin works as a normal SPI output. Set the DSDO bit to '1' to disable the SDO pin. The SDO pin is always in a Hi-Z state no matter what the status of the CS pin is.  |
| D5    | NOP    | 0       | No operation bit.  During a write operation, setting the NOP bit to '1' has no effect (the bit returns to '0' when the write operation completes).  Setting the NOP bit to '0', returns the device to normal operation.  During a read operation, the bit always returns "0"   |
| D4    | W2     | 0       | Second wake-up operation bit. If the $\overline{WAKEUP}$ pin is high, an alternative method to wake-up the device from sleep in SPI is by using the $\overline{CS}$ pin. When $W2 = '1'$ , the rising edge of $\overline{CS}$ restores the device from sleep mode to normal operation, if no more than one falling edge of SCLK exists while $\overline{CS}$ is low. However, the device will not wake up if more than one falling edge of SCLK exists. Setting the $W2$ bit to '0' disables this function, and the rising edge of $\overline{CS}$ does not wake up the device. If the $\overline{WAKEUP}$ is low, this bit is ignored and the device is always in normal mode.  |
| D3:D0 | _      | 0       | Reserved. Writing to these bits has no effect; reading these bits returns '0'.   |

#### Monitor Register (default = 0000h).

The Monitor Register selects one of the DAC outputs, auxiliary analog inputs, reference buffer outputs, or offset DAC outputs to be monitored through the  $V_{MON}$  pin. When bits [D15:D4] = '0', the monitor is disabled and  $V_{MON}$  is in a Hi-Z state.

Note that if any value is written other than those specified in Table 12, the Monitor Register stores the invalid value; however, the  $V_{MON}$  pin is forced into a Hi-Z state.

Table 12. Monitor Register (Default = 0000h)

| D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3:D0            | V <sub>MON</sub> CONNECTS TO              |  |

<sup>(1)</sup> X = don't care.

#### GPIO Register (default = 3800h).

The GPIO Register determines the status of each GPIO pin.

| D15    | D14    | D13    | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|--------|--------|--------|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| GPIO-2 | GPIO-1 | GPIO-0 | X   | X   | X   | X  | X  | Х  | Х  | X  | X  | X  | Х  | X  | Х  |

**GPIO-2:0** For write operations, the GPIO-n pin operates as an output. Writing a '1' to the GPIO-n bit sets the GPIO-n pin to high impedance, and writing a '0' sets the GPIO-n pin to logic low. An external pull-up resistor is required when using the GPIO-n pin as an output.

For read operations, the GPIO-n pin operates as an input. Read the GPIO-n bit to receive the status of the corresponding GPIO-n pin. Reading a '0' indicates that the GPIO-n pin is low, and reading a '1' indicates that the GPIO-n pin is high.

After power-on reset, or any forced hardware or software reset, all GPIO-n bits are set to '1', and the GPIO pins are in a high impedance state.

Offset DAC-A/B Registers (default = 2666h for dual supplies or 0000h for single supplies).

The Offset DAC-A and Offset DAC-B registers contain, by default, the factory-trimmed Offset DAC code providing optimal offset and span for symmetric bipolar operation when dual supplies are detected, and contain code 0000h when a single supply is detected.

| D15  | D14  | D13  | D12  | D11 | D10 | D9  | D8  | D7  | D6  | D5  | D4  | D3  | D2  | D1 | D0 |
|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|----|----|
| OS13 | OS12 | OS11 | OS10 | OS9 | OS8 | OS7 | OS6 | OS5 | OS4 | OS3 | OS2 | OS1 | OS0 | Χ  | Х  |

#### OS13:0

For dual-supply operation, the default code for a gain of 6 is 2666h with a ±3 LSB variation, depending on the linearity of each Offset DAC. The default code for a gain of 4 is 2AABh with a ±3 LSB variation. The default codes of Offset DAC-A and Offset DAC-B registers are independently factory trimmed for both gains of 6 and 4.

When single-supply operation is present, writing to these registers is ignored and reading returns 0000h. When dual-supply operation is present, updating the GAIN-A (GAIN-B) bit on the configuration register automatically reloads the factory-trimmed code into the Offset DAC-A (Offset DAC-B) register for the new GAIN-A (GAIN-B) setting. See the *Offset DACs* for further details.

### **SPI MODE Register** (default = 0000h).

The SPI Mode Register is used to put the device into SPI sleep mode.

| D15   | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|-------|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| SLEEP | Х   | Х   | Х   | Х   | Χ   | Χ  | Х  | Х  | Х  | Х  | Х  | Χ  | Χ  | Χ  | Х  |

#### **SLEEP**

Set the SLEEP bit to '1' to put the device into SPI sleep mode.

When the SLEEP bit = '0', the SPI is in normal mode. The bit is cleared ('0') after a hardware reset (through the  $\overline{RST}$  pin) or if the  $\overline{WAKEUP}$  pin is low.

For normal SPI operation, the data entering the SDI pin is transferred into the Shift Register. However, for SPI sleep mode, the Shift Register is bypassed. The data entering into the SDI pin are directly transferred to the SDO pin instead of the Shift Register.

#### Broadcast Register.

The DAC8218 broadcast register can be used to update all eight DAC register channels simultaneously using data bits D15:D2. This write-only register uses address A4:A0 = 07h, and is only available when the SCE bit = '0' (default). If the SCE bit = '1', this register is ignored. Reading this register always returns 0000h.

#### Input Data Register for DAC-n, where n = 0 to 7 (default = 0000h).

This register stores the DAC data written to the device when the SCE bit = '1' and is controlled by the correction engine. When the SCE bit = '0' (default), the DAC Data Register stores the DAC data written to the device. When the data are loaded into the corresponding DAC latch, the DAC output changes to the new level defined by the DAC latch. The default value after power-on or reset is 0000h.

Table 13. DAC-n<sup>(1)</sup> Input Data Register

| MSB                 |      |      |      |     |     |     |     |     |     |     |     |     |     |    | LSB |

#### **Zero Register n, where n = 0 to 7** (default = 0000h).

The Zero Register stores the user-calibration data that are used to eliminate the offset error. The data are 14 bits wide, 1 LSB/step, and the total adjustment is –16384 LSB to +16383 LSB, or ±50% of full-scale range. The Zero Register uses a twos complement data format.

#### Table 14. Zero Register

# Gain Register n, where n = 0 to 7 (default = 2000h).

The Gain Register stores the user-calibration data that are used to eliminate the gain error. The data are 14 bits wide, 0.0015% FSR/step, and the total adjustment range 0.5 to 1.5. The Gain Register uses a straight binary data format.

#### Table 15. Gain Register

#### **APPLICATION INFORMATION**

#### **BASIC OPERATION**

The DAC8218 is a highly-integrated device with high-performance reference buffers and output buffers, greatly reducing the printed circuit board (PCB) area and production cost. On-chip reference buffers eliminate the need for a negative external reference. Figure 101 shows a basic application for the DAC8218.

NOTES: AVDD = +15V, AVSS = -15V, DVDD = +5V, IOVDD = +1.8V to +5V, REF-A = +5V, and REF-B = +2.5V. The OFFSET-A and OFFSET-B pins must be connected to the AGND pin when used in unipolar operation.

Figure 101. Basic Application Example

#### PRECISION VOLTAGE REFERENCE SELECTION

To achieve the optimum performance from the DAC8218 over the full operating temperature range, a precision voltage reference must be used. Careful consideration should be given to the selection of a precision voltage reference. The DAC8218 has two reference inputs, REF-A and REF-B. The voltages applied to the reference inputs are used to provide a buffered positive reference for the DAC cores. Therefore, any error in the voltage reference is reflected in the outputs of the device. There are four possible sources of error to consider when choosing a voltage reference for high-accuracy applications; initial accuracy, temperature coefficient of the output voltage, long-term drift, and output voltage noise. Initial accuracy error on the output voltage of an external reference can lead to a full-scale error in the DAC. Therefore, to minimize these errors, a reference with low initial accuracy error specification is preferred. Long-term drift is a measure of how much the reference output voltage drifts over time. A reference with a tight, long-term drift specification ensures that the overall solution remains relatively stable over its entire lifetime. The temperature coefficient of a reference output voltage affects the output drift when the temperature changes. Choose a reference with a tight temperature coefficient specification to reduce the dependence of the DAC output voltage on ambient conditions. In high-accuracy applications, which have a relatively low noise budget, the reference output voltage noise also must be considered. Choosing a reference with as low an output noise voltage as practical for the required system resolution is important. Precision voltage references such as TI's REF50xx (2V to 5V) and REF32xx (1.25V to 4V) provide a low-drift, high-accuracy reference voltage.

#### **POWER-SUPPLY NOISE**

The DAC8218 must have ample supply bypassing of  $1\mu F$  to  $10\mu F$  in parallel with  $0.1\mu F$  on each supply, located as close to the package as possible; ideally, immediately next to the device. The  $1\mu F$  to  $10\mu F$  capacitors must be the tantalum-bead type. The  $0.1\mu F$  capacitor must have low effective series resistance (ESR) and low effective series inductance (ESI), such as common ceramic types, which provide a low-impedance path to ground at high frequencies to handle transient currents because of internal logic switching. The power-supply lines must be as large a trace as possible to provide low-impedance paths and reduce the effects of glitches on the power-supply line. Apart from these considerations, the wideband noise on the  $AV_{DD}$ ,  $AV_{SS}$ ,  $DV_{DD}$  and  $IOV_{DD}$  supplies should be filtered before feeding to the DAC to obtain the best possible noise performance.

#### **LAYOUT**

Precision analog circuits require careful layout, adequate bypassing, and a clean, well-regulated power supply to obtain the best possible dc and ac performance. Careful consideration of the power-supply and ground-return layout helps to meet the rated performance. DGND is the return path for digital currents and AGND is the power ground for the DAC. For the best ac performance, care should be taken to connect DGND and AGND with very low resistance back to the supply ground. The PCB must be designed so that the analog and digital sections are separated and confined to certain areas of the board. If multiple devices require an AGND-to-DGND connection, the connection is to be made at one point only. The star ground point is established as close as possible to the device.

The power-supply traces must be as large as possible to provide low impedance paths and reduce the effects of glitches on the power-supply line. Fast switching signals must never be run near the reference inputs. It is essential to minimize noise on the reference inputs because it couples through to the DAC output. Avoid crossover of digital and analog signals. Traces on opposite sides of the board must run at right angles to each other. This configuration reduces the effects of feedthrough on the board. A microstrip technique may be considered, but is not always possible with a double-sided board. In this technique, the component side of the board is dedicated to the ground plane, and signal traces are placed on the solder-side.

Each DAC group has a ground pin, AGND-x, which is the ground of the output from the DACs in the group. It must be connected directly to the corresponding reference ground in low-impedance paths to get the best performance. AGND-A must be connected with REFGND-A and AGND-B must be connected with REFGND-B. AGND-A and AGND-B must be tied together and connected to the analog power ground and DGND.

During single-supply operation, the OFFSET-x pins must be connected to AGND-x with a low-impedance path because these pins carry DAC-code-dependent current. Any resistance from OFFSET-x to AGND-x causes a voltage drop by this code-dependent current. Therefore, it is very important to minimize routing resistance to AGND-x or to any ground plane that AGND-x is connected to.

<sup>(1)</sup> Status: For more details on status, see our product life cycle.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

<sup>(2)</sup> **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

<sup>(3)</sup> RoHS values: Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

<sup>(4)</sup> Lead finish/Ball material: Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

<sup>(5)</sup> MSL rating/Peak reflow: The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

<sup>(6)</sup> Part marking: There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.
