TPS9260x-Q1 Single- and Dual-Channel Automotive Headlight LED Driver

Technical

Documents

1 Features

- Qualified for Automotive Applications
- AEC-Q100 Qualified With the Following Results:
 - Device Temperature Grade 1: -40°C to 125°C Ambient Operating Temperature
 - Device HBM ESD Classification Level 2
 - Device CDM ESD Classification Level C4B
- Input Voltage: 4 V–40 V (45 V Abs. Max.)
- Output Voltage: 4 V-75 V (80 V Abs. Max.)
- Fixed-Frequency Current-Mode Controller With Integrated Slope Compensation
- Two Regulation Loops, Constant-Current Output and Constant-Voltage Output of Each Channel
- High-Side Current Sense:
 - 150-mV or 300-mV Sense Voltage (EEPROM Option)
 - ±6-mV Offset (Achieving Approx. 4% or 2% LED Current Accuracy)
- Output Voltage Sense, Internal Voltage Reference: 2.2 V ±5%
- Integrated Low-Side NMOS-FET Driver: Peak Gate-Drive Current Typ. 0.7 A
- Frequency Synchronization
- Both PWM Dimming and Analog Dimming
- Diagnostic:
 - High-Side Current (LED Current) Available as Analog Output
 - Open-LED and Short-to-GND Detection
 - Shorted Output Protection
- Internal Under- and Overvoltage Lockout

2 Applications

- Automotive Headlight LED Driver
- High-Brightness LED Applications

3 Description

Tools &

Software

The TPS9260x-Q1 family of devices is a singlechannel and dual-channel high-side-current LED driver. With full protection and diagnostics, this family of devices is dedicated for and ideally suited to automotive front lighting. The base of each independent driver is a peak-current-mode boost controller. Each controller has two independent feedback loops, a current-feedback loop with a highside current-sensing shunt and a voltage-feedback loop with an external resistor-divider network. The controller delivers a constant output voltage or a constant output current. The connected load determines whether the device regulates a constant output current (if the circuit reaches the current setpoint earlier than voltage set-point) or a constant output voltage (if the circuit reaches the voltage setpoint is reached first, for example, in an open-load condition).

Support &

Community

20

Each controller supports all typical topologies such as boost, boost-to-battery, SEPIC, or flyback.

Uses of the high-side PMOS FET driver are for PWM dimming of the LED string and for cutoff in case of an external short circuit to GND to protect the circuit.

Device Information(1)					
PART NUMBER	CHANNELS				
TPS92601-Q1, TPS92601B-Q1	15 mV–150 mV	1			
TPS92601A-Q1(2)	30 mV–300 mV	1			
TPS92602-Q1, TPS92602B-Q1	15 mV–150 mV	2			
TPS92602A-Q1(2)	30 mV–300 mV	2			

Device Information(1)

(1) For all available packages, see the orderable addendum at the end of the datasheet.

(2) Device is available as a preview only.

4 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Cł	anges from Revision D (January 2015) to Revision E Page				
•	Changed Device Information table	1			
•	Changed the pinout diagrams	3			
•	Changed VCC to V _{CC} throughout the data sheet	4			

Changes from Revision C (September 2014) to Revision D

•	Changed the device status for the TPS92601-Q1 from Product Preview to Production Data	1
•	Added single-channel in addition to the dual-channel text throughout the data sheet	1
•	Changed the Handling Ratings table to ESD Ratings and moved the storage temperature to the Absolute Maximum Ratings table	4
•	Updated the units of the Q(GS) equation (Equation 37)	. 24
•	Updated the units of the Q(GS) equation (Equation 71) and the resulting values	. 31
•	Updated the r _{DS(on)} values as a result of Equation 72.	. 31

Changes from Revision B (August 2014) to Revision C Page Changed the package type for the TPS92601-Q1 and TPS92601A-Q1...... 3 Changes from Revision A (April 2014) to Revision B

•	Added a column to the Device Comparison table	1
•	Changed Device Information table	1
•	Changed pinout diagram and combined Pin Function tables	3

Changes from Original (March 2014) to Revision A

Added all new content following the first page 3

6 Specifications

6.1 Absolute Maximum Ratings⁽¹⁾⁽²⁾⁽³⁾

over operating free-air temperature (unless otherwise noted)

		MIN	MAX	UNIT
Supply voltage	VIN, PWMINx ⁽⁴⁾	-0.3	40	V
Output voltage	VOUTx, ISPx, ISNx, PWMOx ⁽⁴⁾	-0.3	80	V
Differential voltage	(VOUTx – PWMOx) ⁽⁴⁾	-0.3	8.8	V
Grounds	PGNDx ⁽⁴⁾	-0.3	0.3	V
	GDRVx, ISNSx ⁽⁴⁾	-0.3	8.8	V
Other size	OVFBx ⁽⁴⁾	-0.3	80	V
Other pins	V _{cc}	-0.3	8.8	V
	ICTRLx, COMPx, RT, DIAGx ⁽⁴⁾	-0.3	3.6	V
V _{CC} current	Gate-driver supply		220	mA
Junction temperature, T _J		-40	150	°C
Storage temperature, T _{stg}		-55	150	°C

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, and do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods my affect device reliability.

(2) The algebraic convention, whereby the most-negative value is a minimum and the most-positive value is a maximum.

(3) All voltages are with respect to ground (GND pin), unless otherwise specified.

(4) For the TPS9602-Q1 device, x = 1 or 2. For the TPS9601-Q1 device, x is blank.

6.2 ESD Ratings

				VALUE	UNIT
V _(ESD)		Human-body model (HBM), per AEC Q100-002 ⁽¹⁾		±2000	
			Other pins	±500	
	Electrostatic discharge	Charged-device model (CDM), per AEC Q100-011	Corner pins (1, 14, 15, 28 for TPS92602x-Q1; 1, 10, 11, 20 for TPS92601x-Q1)	±750	V

(1) AEC Q100-002 indicates HBM stressing is done in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

6.3 Recommended Operating Conditions

over operating free-air temperature (unless otherwise noted)

			MIN	MAX	UNIT
		VIN (first connection to battery, full functionality)	6	26	V
	Supply voltage	VIN (battery voltage during cranking profile, full functionality)	4	26	V
		VIN	26	40	V
	Output sense	VOUTx, ISPx, ISNx ⁽¹⁾	4	75	V
		PWMINx: enable and disable functionality ⁽¹⁾	0	40	V
	PWMIN	PWMINx: PWM functionality ⁽¹⁾	0	7	V
		ISNSx, OVFBx ⁽¹⁾	0	8	V
Other pins	V _{cc}	3	8	V	
		ICTRLx, RT ⁽¹⁾	0	3.3	V
	Gate-driver supply cu	rrent, V _{CC} ⁽²⁾		100	mA
T _A	Ambient temperature	range	-40	125	°C
TJ	Junction temperature	range	-40	150	°C

(1) For the TPS9602-Q1 device, x = 1 or 2. For the TPS9601-Q1 device, x is blank.

(2) Note available current for low-side gate drivers to drive the external BOOST FETs

6.4 Thermal Information

	THERMAL METRIC ⁽¹⁾	TPS92601-Q1 PWP (HTSSOP) 20 PINS	TPS92602-Q1 PWP (HTSSOP) 28 PINS	UNIT
$R_{\theta JA}$	Junction-to-ambient thermal resistance	37	37.2	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	23.4	19.3	°C/W
R_{\thetaJB}	Junction-to-board thermal resistance	17.7	16.7	°C/W
ΨJT	Junction-to-top characterization parameter	0.9	0.8	°C/W
Ψјв	Junction-to-board characterization parameter	17.5	16.5	°C/W
R _{0JC(bot)}	Junction-to-case (bottom) thermal resistance	0.9	2.6	°C/W

(1) For more information about traditional and new thermal metrics, seeSemiconductor and IC Package Thermal Metrics application report, SPRA953.

6.5 Electrical Characteristics

 $T_J = -40^{\circ}C$ to 150°C, $V_{VDD} = 12$ VDC, over recommended operating conditions (unless otherwise noted)

6.6 Typical Characteristics

Load is eight LEDs per channel at 500 mA, $-40^{\circ}C \le T_A \le 125^{\circ}C$, $-40^{\circ}C \le T_J \le 150^{\circ}C$, $C_{(COMP)} = 0.22 \ \mu\text{F}$, unless otherwise noted.

8

Typical Characteristics (continued)

Load is eight LEDs per channel at 500 mA, $-40^{\circ}C \le T_A \le 125^{\circ}C$, $-40^{\circ}C \le T_J \le 150^{\circ}C$, $C_{(COMP)} = 0.22 \ \mu\text{F}$, unless otherwise noted.

TEXAS INSTRUMENTS

7 Detailed Description

7.1 Overview

The TPS92602y-Q1 device is a dual-channel LED driver. The base of each independent driver is a peak-currentmode boost controller. The two boost controllers operate 180° out-of-phase in order to reduce ripple currents and radiation.

Each controller is independently configurable to regulate the output current (the typical case for driving LEDs) or to regulate the output voltage. Depending on the chosen configuration for each channel, one loop is active while the other loop only acts in case of a failure condition. In a constant-current application, the inactive voltage loop sets the maximum output-voltage limit (and hence becomes active in case of output overvoltage due to an open LED). In constant-voltage applications, the inactive current loop sets the maximum output current limit (and hence becomes active in case of output overvoltage applications, the inactive current loop sets the maximum output current limit (and hence becomes active in case of output overcurrent because of an LED short to ground).

The TPS92601y-Q1 device is a single-channel version of the TPS92602y-Q1 device. Both devices have the same functions.

7.2 Functional Block Diagram

Functional Block Diagram (continued)

Note: The SEPIC and flyback topologies require two extra diodes per channel for start-up, because the minimum common-mode voltage of the current-regulation amplifier is 4 V.

Figure 11. Supported Topologies per Channel

7.3 Feature Description

7.3.1 Fixed-Frequency PWM Control

Each boost controller uses an adjustable fixed-frequency peak-current-mode control. In a constant-current application, the device senses the output current across an external shunt resistor at the ISPx and ISNx pins, amplifies and level-shifts it to ground-reference, and compares it to the voltage applied on the ICTRLx pin by the primary error amplifier, which drives the COMPx pin. In a constant-voltage application, the device compares the output voltage through external resistors on the OVFBx pin to an internal 2.2-V voltage reference by a secondary error amplifier, which drives the COMPx pin. Depending on the chosen application, only one of the error amplifiers is active.

An internal oscillator initiates the turnon of the external boost-power NMOS switch. The device compares the error-amplifier output to the switch current sensed on the ISNSx pin. When the power-switch current reaches the level set by the COMPx voltage, the power NMOS switch turns off. The COMPx pin voltage increases and decreases as the output current increases and decreases. The device implements a current limit by clamping the COMPx pin voltage to a maximum level.

7.3.2 Slope-Compensation Output Current

Each controller adds a compensating ramp to the switch-current signal. This slope compensation prevents subharmonic oscillations. The available peak inductor current remains constant over the full duty-cycle range.

Feature Description (continued)

7.3.3 Boost-Current Limit

Each controller achieves peak-current-mode control using a comparator that monitors the current through the external boost FET at the ISNSx pin by comparing it with the voltage on the COMPx pin. A redundant current-limit comparator, which compares the voltage on the ISNSx pin with a typical 100-mV reference voltage, limits the current through the external boost FET. If the voltage on the ISNSx pin exceeds this typical 100-mV threshold, the on-cycle of the respective boost controller immediately terminates. The current-limit comparator has a lead-edge blanking time to avoid any unwanted triggering of the current limit during switch-on of the external boost FET. One can set the current-limit level with an external resistor, as calculated with the following equation.

$$I_{(\text{Lim})} = \frac{100 \text{ mV}}{\text{R}_{(\text{LIM})}}$$
(1)

7.3.4 Oscillator and PLL

The switching frequency is adjustable over a range from 100 kHz to 600 kHz by placing a resistor on the RT pin. The RT pin voltage is typically 0.5 V and must have a resistor to ground to set the switching frequency. To determine the timing resistance for a given switching frequency, use Equation 2 or the curve in Figure 4. To reduce the solution size one would typically set the switching frequency as high as possible, but give consideration to tradeoffs of the supply efficiency, maximum input voltage, and minimum controllable on-time.

$$R_{RT}[k\Omega] = \frac{12.5 \text{ MHz} \times 1 \text{ k}\Omega}{f_{(OSC)}[MHz]}$$
(2)

One can also use the RT pin to synchronize the controllers to an external system clock, over a range from 100 kHz to 600 kHz. Apply a square wave to the RT pin to use this synchronization feature. The square wave must transition lower than 0.8 V and higher than 2 V on the RT pin and have an on-time greater than 70 ns and an off time greater than 70 ns. The synchronization frequency range is 100 kHz to 600 kHz. The rising edge of GDRV1 is synchronized to the falling edge of the RT pin signal.

Leaving the RT pin open or shorted to ground with no external system clock signal is present disables both boost controllers, and both PWM dimming FETs switch off. In order to recover from this global failure state, (for example, after the failure condition on the RT pin has been removed) there must be one global disable-and-enable cycle (active shutdown by pulling both PWMINx pins low for t > $t_{(CH_OFF)}$, and setting one or both PWMINx pins high for t > $t_{(CH_OFF)}$).

7.3.5 Control Loop Compensation

Modeling of the TPS9260xy-Q1 control loop is like that for any current-mode controller. Using a first-order approximation, one can model the uncompensated loop as a single pole created by the output capacitor and, in the boost and buck-boost topologies, a right half-plane zero created by the inductor, where both have a dependence on the dynamic resistance of the LED string. There is also in the model a high-frequency pole which, however, is near the switching frequency and plays no part in the compensation design process. Therefore, the loop analysis neglects this high-frequency pole. Because TI recommends ceramic capacitors for use with LED drivers due to long lifetimes and high ripple-current rating, one can also neglect the ESR of the output capacitor in the loop analysis. Finally, there is a dc gain of the uncompensated loop which depends on internal controller gains and the external sensing network. A boost regulator serves as an example case. See the *Detailed Design Procedure* section for compensation of all topologies.

Equation 3 gives the whole-loop gain for a boost regulator.

$$T_{u} = T_{uo} \times \frac{\left(1 + \frac{s(j)}{\omega_{ezc}}\right) \times \left(1 - \frac{s(j)}{\omega_{ezrhp}}\right)}{\left(1 + \frac{s(j)}{\omega_{ep0}}\right)}$$

Equation 4 approximates the output pole (ω_{ep0}).

(3)

(4)

(7)

(8)

Feature Description (continued)

$$\omega_{ep0} = \frac{2}{r_{(D)} \times C_o}$$

where

- r_(D): LED and R_(ILED_SNS) dynamic resistance
- C_o: Output capacitor

Use Equation 5 to calculate the right half-plane zero (
$$\omega_{ezrhp}$$
).

$$\omega_{\text{ezrhp}} = \frac{r_{(D)} \times D^{2}}{L1}$$
(5)

Use Equation 6 to calculate the output capacitor and ESR zero (ω_{ezc}).

$$\omega_{\text{ezc}} = \frac{1}{r_{\text{esr}} \times C_{\text{o}}}$$
(6)

The EA transfer function with compensation capacitor and resistor of the system is described in Equation 7 is shown in Equation 7.

$$T_{uo} = Adc \times \frac{\left(1 + \frac{s(j)}{\omega ez1}\right)}{\left(1 + \frac{s(j)}{\omega ep1}\right) \times \left(1 + \frac{s(j)}{\omega ep2}\right)}$$

where

Adc is the error-amplifier (EA) dc gain

Use Equation 8 to calculate the EA output with compensation capacitor pole (ω_{ep1}).

$$\omega_{\rm ep1} = \frac{1}{R_{\rm (o)} \times C_z}$$

where

R_(o) is the EA output impendence

The EA higher frequency pole (ω_{ep2} to filter the high-frequency noise, which is higher than whole-loop bandwidth) is shown in Equation 9.

$$\omega_{\text{ep2}} = \frac{1}{R_z \times C_p} \tag{9}$$

The EA output ESR zero (ω_{ez1}) is shown in Equation 10.

$$\omega_{ez1} = \frac{1}{R_z \times C_z}$$
(10)

Compensator design should give adequate phase margin (above 45°) at the crossover frequency. A simple compensator using a single capacitor at the COMP pin adds a dominant pole to the system, which ensures adequate phase margin if placed low enough. At high duty cycles, the RHP zero places extreme limits on the achievable bandwidth with this type of compensation. However, because an LED driver is essentially free of output transients (except catastrophic failures, open or short), the dominant pole approach, even with reduced bandwidth, is usually the best approach.

7.3.6 LED Open-Circuit Detection

An open LED in any channel interrupts the current flow of that channel. If the LED current in the sensing circuit falls below the defined threshold th_{OLED} , then the device pulls the DIAGx pin of the affected channel low (for example, for use as an interrupt to a microcontroller). The output-voltage regulation is with respect to the set point of the voltage-control loop (resistor divider network on the OVFBx pin). Removal of the failure releases the DIAGx pin automatically.

Copyright © 2014–2018, Texas Instruments Incorporated

Feature Description (continued)

7.3.7 Output Short-Circuit and Overcurrent Detection

In case of an external short circuit of a boost output supply line to GND, the respective boost controller of the affected channel is no longer able to limit the current through the control loop. This is because of the conductive path from the supply voltage to the shorted output through the inductor and the boost diode.

To protect the external components from excessive currents, the controller of the affected channel interrupts the path to its output by switching off the high-side PWM-dimming PMOS-FET. The interruption occurs as soon as the high-side current-sense amplifier detects a common-mode voltage below 4 V, or when the voltage on the VOUTx pin is below 4 V, or once the high-side current-sense amplifier hits the shorted-output detection threshold $V_{(OPLED)}$. The protection of each channel operates in this way, independently of the other channel (see state-diagram in Figure 14). The device pulls the DIAGx pin of the affected channel high, and the controller of the affected channel remains in this channel-fail state. In order to reset the controller of the affected channel (for example, after removal of a short circuit) there must be one disable-and-enable cycle for the affected channel by pulling the PWMINx pin low for t > t_(CH_OFF), and setting it high for t > t_(CH_ON).

7.3.8 Measuring LED Current During a Non-Failure Condition

In regular operation mode, one can measure the actual output current of the controller with an external microcontroller by sensing the voltage at the DIAGx pin. The DIAGx pin voltage between 0.2 V and 2.85 V represents in a linear relation the output current measured by the current-sense block across the external shunt resistor. Parameter DIAG_{factor} gives the scale factor of typically 12.5 (the TPS92601y-Q1 or TPS92602y-Q1 device with 150-mV full-scale current-sense voltage) or 6.25 (the TPS92601A-Q1 or TPS92602A-Q1 device with 300-mV full-scale current-sense voltage). Figure 12 gives the relation between the DIAGx pin voltage and the current-sense voltage.

Figure 12. DIAGx Pin Function

When the device is in global shutdown mode (when both PWMINx pins go low for t > $t_{(CH_OFF)}$), both DIAGx pins are low.

Feature Description (continued)

7.3.9 LED Dimming Options

The device offers two different approaches to regulate and control the brightness and the color of the LEDs: analog dimming and PWM dimming.

7.3.9.1 Analog Dimming

An analog voltage applied to the ICTRLx pin allows changing the output current for each channel on the fly from 10%–100% of full-scale. Typically, this approach is used to:

- Reduce the default current in a narrow range to adjust to different binning classes of the LEDs
- · Reduce the current at high temperatures (protect LEDs from overtemperature)
- Reduce the current at low input voltages (for example, cranking-pulse breakdown of the supply)

Implementing this analog dimming function is possible with an analog approach (discrete resistor and NTC network) or with a more-flexible approach by using a microcontroller. Internally clamping the maximum voltage on the ICTRLx pin at 1.5 V simplifies the analog implementation. So applying any higher voltage has no effect on the output current (which remains at its current set point at 100% of full scale, that is, 150 mV or 300 mV drop at the external current shunt resistor).

Figure 13. Analog Dimming – ICTRLx Pin

7.3.9.2 PWM Dimming

To change the brightness of an LED string by a certain magnitude without affecting the lighting-color of the LED, it is necessary to use PWM dimming topology. Turning the LEDs ON and OFF at a certain frequency with a certain duty cycle reduces the brightness without changing the LED current (so not affecting the color).

The integrated high-side PMOS-FET gate driver turns the LED string ON and OFF following the supplied signal frequency and duty cycle on the PWMIN pin. During the OFF time of the FET, the device stops the internal control loop by disconnecting the loop internally and then stores the value of the compensation network. This technique allows fastest recovery of the regulator with the following ON time, as the control loop restarts from the point at which it stopped. The average LED current during ON time is almost the same as the LED current with no PWM dimming (duty cycle 100%). For very low duty cycles, the time required by the controller to ramp up the inductor current form 0 A becomes more significant relative to the overall ON time, leading to lower average current. So for very low duty cycles, the relation between average current and duty cycle is no longer linear.

Copyright © 2014–2018, Texas Instruments Incorporated

Feature Description (continued)

One must maintain a minimum on-time in order for PWM dimming to operate in the linear region of its transfer function. Because of disabling the controller during dimming, the PWM pulse must be long enough that the energy intercepted from the input is greater than or equal to the energy being put into the LEDs. For boost and boost-to-battery topologies, the minimum ON time (in seconds) for which the PWM dimming operates in the linear region is:

$$t_{(PWMON_MIN)} = \frac{2 \times I_{(LED)} \times V_{(out)} \times L}{V_{(IN)}^2}$$
(11)

To ensure that the applied dimming-pulse duration matches with the effective dimming-pulse duration, TI recommends synchronizing the dimming pulses with the switching clock of the boost converter. Choose the external inductor and output capacitors according to the requirements for the minimum duty cycle.

7.4 Device Functional Modes

7.4.1 Undervoltage and Overvoltage Shutdown

During normal operation (6 V < $V_{(V|N)}$ < 40 V), when the supply voltage at the VIN pin drops below 4 V during cranking, each boost controller is disabled (when previously in normal operation). As long as the battery voltage stays above 3.5 V, both PWM dimming FETs are still controllable through the PWMINx pins, and the V_{CC} regulator is still active. The supply voltage recovering above 4 V re-enables each boost controller (which was working normally before the supply voltage drop). When supply voltage at the VIN pin drops below 3.5 V, the device enters standby due to battery undervoltage. From standby mode, re-enabling the device can only occur when the supply voltage is above 6 V and one or both PWMINx pins are high for t > t_(CH_ON)). See the state diagram in Figure 14. When the supply voltage at the VIN pin goes above 40 V during load-dump, the device disables both boost controllers due to battery overvoltage, and switches both PWM dimming FETs off. The V_{CC} regulator is still active. Once the battery voltage is below 40 V, the device recovers from this global failure state after a global disable-and-enable cycle (active shutdown by pulling both PWMINx pins low for t > t_(CH_OFF), and setting one or both PWMINx pins high for t > t_(CH_ON)). See the state diagram in Figure 14.

7.4.2 Overtemperature Shutdown

When the junction temperature rises above 165°C, both boost controllers are disabled due to junction overtemperature, and both PWM dimming FETs are switched off. Once the junction temperature is below 145°C, the device recovers from this global failure state or a global disable-and-enable cycle (active shutdown by pulling both PWMINx pins low for t > $t_{(CH_OFF)}$, and setting one or both PWMINx pins high for t > $t_{(CH_OFF)}$). See the state diagram in Figure 14.

7.4.3 Device State Diagram

Figure 14 shows the state diagram of the device, with a short description of the device behavior in each state.

Device Functional Modes (continued)

Channelx Failure Detected = (V_(VOUTx) < 4 V OR V_(SPSNx_Com) < 4V OR V_(SPSNx_Diff) > th_(SHOUT))

NOTE: In the case of an open LED on channel x, the DIAGx pin is low, but the boost controller and the PWM dimming FET of channel x work normally. Hence, the behavior is as in the ON state or the low-voltage state.

Figure 14. Device State Diagram

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

This section describes the application-level considerations when designing with the TPS9260xy-Q1 family of devices. For corresponding calculations, see the following section.

8.2 Typical Applications

In an application directly connected to a battery, if the application is a passenger car, $V_{(VIN)}$ is from 9 V to 16 V, and LED forward voltage is always higher than battery, then one can select the boost topology. If the LED forward voltage is between 9 V and 16 V, boost-to-battery or single-ended primary-inductance converter (SEPIC) topology is appropriate.

8.2.1 Boost Regulator With Separate or Paralleled Channels

A boost application is appropriate for a situation where $V_{(VIN)}$ is from 9 V to 16 V and LED forward voltage is always higher than battery the battery voltage. One can use the boost-regulator topology with each channel driving a separate LED string. For higher-current applications, connect both channels in parallel to drive a single LED string. The per-channel design parameters and calculations are the same in either case.

Typical Applications (continued)

Figure 15. Boost Regulator ($V_{IN} < V_{O}$) Simplified Schematic, Separate Channels

Typical Applications (continued)

Figure 16. Boost Regulator ($V_{IN} < V_O$) Simplified Schematic, Paralleled Channels

Typical Applications (continued)

Figure 17. Boost Regulator ($V_{IN} < V_{O}$) Detailed Schematic

8.2.1.1 Design Requirements

For this boost regulator example, use the following as the design parameters.

Table 1. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
Input voltage range	Connect to battery (6 V to 16 V)
Output current per channel (I _(setting))	1 A
Output voltage	30 V (9 white LEDs)
Input ripple voltage	400 mV
Output ripple current	±10%
Operating frequency	600 kHz

8.2.1.2 Detailed Design Procedure

To begin the design process, one must decide on a few parameters. The designer must know the following:

- Input voltage range
- Output current per channel
- Output voltage
- Input ripple voltage
- Output ripple current
- Operating frequency

Copyright © 2014–2018, Texas Instruments Incorporated

8.2.1.2.1 Switching Frequency

The RT pin resistor sets the switching frequency of the TPS92602y-Q1 device. Use Equation 2 to calculate the required value for R17. The calculated value is 20.83 k Ω . Use the nearest standard value of 20 k Ω .

8.2.1.2.2 Maximum Output-Current Set Point

The constant output current of the TPS92602y-Q1 device is adjustable by using the external current-shunt resistor. In the application circuit of Figure 17, R5 is the channel 1 current-shunt resistor, and R16 is the channel-2 current shunt resistor. Equation 12 and Equation 13 calculate the resistors that determine maximum output current.

$$R_{(sense)} = V_{SPSN_{Diff}} / I_{(setting)}$$
(12)
R5 = R16 = 150 mV / 1 A = 0.15 Ω (13)

8.2.1.2.3 Output Overvoltage-Protection Set Point

The output overvoltage protection threshold of the TPS92602y-Q1 device is externally adjustable using a resistor divider network. In the application circuit of Figure 17, this divider network comprises R1 and R3 for channel1 and R2 and R4 for channel2. The following equation gives the relationship of the overvoltage-protection threshold ($V_{(OVPT)}$) to the resistor divider.

$$R1 / R3 = R2 / R4 = (V_{(OVPT)} - V_{(VFB)}) / V_{(VFB)}$$
(14)

The load is nine white LEDs, the forward voltage is about 30 V. For an overvoltage protection margin of 20%, $V_{(OVPT)}$ is: $V_{(OVPT)} = 30 \times 1.2 = 36$ V. So R1 / R3 = R2 / R4 = (36 - 2.2) / 2.2 = 15.36. Select R3 = R4 = 30 k\Omega; then R1 = R2 = 460 kΩ. Use the nearest standard value of 464 kΩ.

8.2.1.2.4 Duty Cycle Estimation

Estimate the duty cycle of the main switching MOSFET using Equation 15 and Equation 16.

$$D_{(MIN)} \approx \frac{V_{(OUT)} - V_{(IN-max)} + V_{(FD)}}{V_{(OUT)} + V_{(FD)}} = \frac{30 \text{ V} - 16 \text{ V} + \text{DMIN } 0.5 \text{ V}}{30 \text{ V} + 0.5 \text{ V}} = 47.5\%$$

where

D is the duty cycle in these and all following equations (15)

$$D_{(MAX)} \approx \frac{V_{(OUT)} - V_{(IN-min)} + V_{(FD)}}{V_{(OUT)} + V_{(FD)}} = \frac{30 \text{ V} - 6 \text{ V} + 0.5 \text{ V}}{30 \text{ V} + 0.5 \text{ V}} = 80.3\%$$
(16)

Using an estimated forward drop of 0.5 V for a Schottky rectifier diode, the approximate duty cycle is 47.5% (minimum) to 80.3% (maximum).

8.2.1.2.5 Inductor Selection

The peak-to-peak ripple is limited to 30% of the maximum output current.

$$I_{(Lrip-max)} = 0.3 \times \frac{I_{(OUT-max)}}{1 - D_{(MIN)}} = 0.3 \times \frac{1}{1 - 0.475} = 0.571 \,\text{A}$$
(17)

Estimate the minimum inductor size using Equation 18.

$$L_{(MIN)} \gg \frac{V_{(IN-max)}}{I_{(Lrip-max)}} \times D_{(MIN)} \times \frac{1}{f_{(SW)}} = \frac{16 \text{ V}}{0.571 \text{ A}} \times 0.475 \times \frac{1}{600 \text{ kHz}} = 22.1 \,\mu\text{H}$$
(18)

Select the nearest standard inductor value of 22 µH. Estimate the ripple current using Equation 19.

$$I_{(RIPPLE)} \approx \frac{V_{(IN)}}{L} \times D_{(MIN)} \times \frac{1}{f_{(SW)}} = \frac{16 \text{ V}}{22 \ \mu \text{H}} \times 0.475 \times \frac{1}{600 \ \text{kHz}} = 0.575 \text{ A}$$
(19)

$$I_{(\text{RIPPLE-Vinmin})} \approx \frac{V_{(\text{IN})}}{L} \times D_{(\text{MIN})} \times \frac{1}{f_{(SW)}} = \frac{6 \text{ V}}{22 \ \mu\text{H}} \times 0.475 \times \frac{1}{600 \ \text{kHz}} = 0.365 \text{ A}$$
(20)

The worst-case peak-to-peak ripple current occurs at 47.5% duty cycle and is estimated as 0.575 A. Equation 21 estimates the worst-case rms current through the inductor.

(21)

$$I_{(Lrms)} = \sqrt{\left(I_{(L-avg)}\right)^2 + \left(\left[\frac{1}{12} \times I_{(RIPPLE)}\right]\right)^2} \approx \sqrt{\left(\frac{I_{(OUT-max)}}{1 - D_{(MAX)}}\right)^2 + \left(\frac{1}{12} \times I_{(RIPPLE-Vinmin)}\right)^2}$$
$$= \sqrt{\left(\frac{1A}{1 - 0.803}\right) + \left(\frac{1}{12} \times 0.365 \text{ A}\right)^2} = 5.08 \text{ A rms}$$

The worst-case rms inductor current is 5.08 A rms. Equation 22 estimates the peak inductor current.

$$I_{(Lpeak)} \approx \frac{I_{(OUT-max)}}{1 - D_{(MAX)}} + \frac{1}{2} \times I_{(RIPPLE-Vinmin)} = \frac{1}{1 - 0.083} + 0.5 \times 0.365 = 5.26 \text{ A}$$
(22)

Select a 22- μ H inductor with a minimum rms current rating of 5.08 A and minimum saturation current rating of 5.26 A. The selection is a Wurth 74435572200 inductor (shielded-drum core, ferrite, 22 μ H, 11 A, 0.0146 Ω , SMD).

Equation 23 estimates the power dissipation of this inductor

$$\mathsf{P}_{(\mathsf{L})} \approx (\mathsf{I}_{(\mathsf{Lrms})})^2 \times \mathsf{DCR}$$
⁽²³⁾

The Wurth 74435572200 inductor with 14.6-m Ω DCR dissipates 404 mW of power.

8.2.1.2.6 Rectifier Diode Selection

The circuit uses a low-forward-voltage-drop Schottky diode as a rectifier diode to reduce power dissipation and improve efficiency. Use 80% derating for the diode on VOUTx to allow for for ringing on the switch node. Equation 24 gives the rectifier-diode minimum reverse-breakdown voltage.

$$V_{(BR)(R-min)} \ge \frac{V_{(VOPT)}}{0.8} = 1.25 \times 36 \text{ V} = 45 \text{ V}$$
 (24)

The diode must have a reverse-breakdown voltage greater than 45 V. Equation 25 and Equation 26 estimate the rectifier diode peak and average currents.

$$I_{(D-avg)} \approx I_{(OUT-max)} = 1 A$$

$$I_{(D-peak)} = I_{(L-peak)} = 5.26 A$$
(25)
(26)

For this design, average current is 1 A and peak current is 5.26 A.

Equation 27 estimates the power dissipation in the diode.

$$\mathsf{P}_{(\mathsf{D}\text{-}\mathsf{max})} \approx \mathsf{V}_{(\mathsf{F})} \times \mathsf{I}_{(\mathsf{OUT}\text{-}\mathsf{max})} = 0.5 \text{ V} \times 1 \text{ A} = 0.5 \text{ W}$$
⁽²⁷⁾

For this design, the maximum power dissipation is estimated as 0.5 W. After reviewing 45-V and 60-V Schottky diodes, the selection is the 30BQ060PbF diode, Schottky, 60 V, 3 A, SMC. This diode has a forward voltage drop of 0.5 V at 1 A, so the conduction power dissipation is approximately 500 mW, less than half its rated power dissipation.

8.2.1.2.7 Output Capacitor Selection

Assume a maximum LED current ripple of 0.1 × $I_{(LED)}$. Also, assume that the dynamic impedance of the chosen LED is 0.2 Ω (1.8 Ω total for the nine-LED string). The total output-voltage ripple calculation is then as per Equation 28.

$$V_{(\text{VOUT-ripple})} = 0.1 \,\text{A} \times 1.8 \,\Omega = 180 \,\text{mV}$$
⁽²⁸⁾

Assuming a ripple contribution of 95% from bulk capacitance, Equation 29 calculates the output capacitor.

$$C_{(OUT)} = \frac{I_{(OUT)} \times D}{V_{(VOUT-ripple)} \times 0.95} \times \frac{1}{f_{(SW)}} = \left(\frac{1 \,\text{A} \times 0.803}{180 \,\text{mV} \times 0.95}\right) \times \frac{1}{600 \,\text{kHz}} = 7.83 \,\mu\text{F}$$
(29)

$$ESR = \frac{V_{(VOUT-ripple)}}{I_{(L-peak)}} = \frac{9 \text{ mV}}{5.26 \text{ A}} = 1.71 \text{ m}\Omega$$
(30)

Copyright © 2014–2018, Texas Instruments Incorporated

NSTRUMENTS

FXAS

www.ti.com

Use three $3.3-\mu$ F capacitors in parallel to achieve the minimum output capacitance of 10 μ F. Ensure that the chosen capacitors meet the minimum bulk capacitance requirement at the operating voltage.

8.2.1.2.8 Input Capacitor Selection

Because a boost converter has continuous input current, the input capacitor senses only the inductor ripple current. Equation 31 and Equation 32 calculate the input capacitor values.

$$C_{(IN)} = \frac{I_{(L-RIPPLE)}}{4 \times v_{(IN-RIPPLE)} \times f_{(SW)}} = \frac{0.575 \text{ A}}{4 \times 60 \text{ mV} \times 600 \text{ kHz}} = 4 \text{ }\mu\text{F}$$

$$ESR = \frac{V_{(VIN-RIPPLE)}}{I_{(L-RIPPLE)}} = \frac{60 \text{ mV}}{2 \times 0.575 \text{ A}} = 52 \text{ }m\Omega$$
(32)

For this design, to meet a maximum input ripple of 60 mV requires a minimum 4- μ F input capacitor with ESR less than 52 m Ω . Select a 10- μ F X7R ceramic capacitor.

8.2.1.2.9 Current Sense and Current Limit

The maximum allowable current sense resistor value is limited by R_(ISNSx). Equation 33 gives this limitation.

$$\mathsf{R}_{(\mathsf{ISNSx})} = \frac{\mathsf{V}_{(\mathsf{SNS})}}{1.3 \times \mathsf{I}_{(\mathsf{L}\text{-peak})}} = \frac{100 \text{ mV}}{1.3 \times 5.26 \text{ A}} = 14.62 \text{ m}\Omega$$
(33)

Select a 15-m Ω resistor.

8.2.1.2.10 Switching MOSFET Selection

The TPS92602y-Q1 device drives a ground-referenced N-channel FET. The breakdown voltage is the output voltage plus any voltage spike, with 30% added for a safety margin as shown in Equation 34.

$$V_{(BD-MOS-min)} \ge V_{(VOPT)} \times 1.3 = 1.3 \times 36 \text{ V} = 46.8 \text{ V}$$
 (34)

Select an N-channel FET with breakdown voltage of 50 V.

Estimate the r_{DS(on)} and gate charge based on the desired efficiency target.

$$\mathsf{P}_{(\mathsf{DISS-total})} \approx \mathsf{P}_{(\mathsf{OUT})} \times \left(\frac{1}{\eta} - 1\right) = 30 \ \mathsf{V} \times 1 \ \mathsf{A} \times \left(\frac{1}{0.95} - 1\right) = 1.578 \ \mathsf{W}$$
(35)

For a target of 95% efficiency with a 16-V input voltage at 1 A, maximum power dissipation is limited to 1.578 W. The main power-dissipating devices are the MOSFET, inductor, diode, current-sense resistor and the integrated circuit, the TPS92602y-Q1 device.

$$P_{(FET)} < P_{(DISS-total)} - P_{(L)} - P_{(D)} - P_{(RSNS)} - V_{(IN-max)} \times I_{(VDD)}$$

$$(36)$$

This assumption leaves 740 mW of power dissipation for the MOSFET. Allowing half for conduction and half for switching losses, we can determine a target $r_{DS(on)}$ and $Q_{(GS)}$ for the MOSFET by Equation 37 and Equation 38.

$$Q_{(GS)} < \frac{3 \times P_{(FET)} \times I_{(DRIVE)}}{2 \times V_{(OUT)} \times I_{(OUT)} \times f_{(SW)}} = \frac{3 \times 0.5 \text{ W} \times 0.7 \text{ A}}{2 \times 30 \text{ V} \times 1 \text{ A} \times 600 \text{ kHz}} = 29.2 \text{ nC}$$
(37)

Calculate a target MOSFET gate-to-source charge of less than 29.2 nC to limit the switching losses to less than 250 mW.

$$r_{DS(on)} < \frac{P_{(FET)}}{2 \times (I_{(RMS)})^2 \times D} = \frac{0.5 \text{ W}}{2 \times (5.08 \text{ A})^2 \times 0.803} = 12 \text{ m}\Omega$$
(38)

Selecting a target MOSFET $r_{DS(on)}$ of 12 m Ω limits the conduction losses to less than 250 mW.

8.2.1.2.11 Loop Compensation

The COMP pin on the TPS92602y-Q1 device is for external compensation, allowing optimization of the loop response for each application. The COMP pin is the output of the internal transconductance amplifier. External resistor R7, along with ceramic capacitors C5 and C6 (see Figure 17), connect to the COMP pin to provide poles and zero. The poles and zero, along with the inherent pole and zero in a peak-current-mode control boost converter, determine the closed-loop frequency response. This connection is important to converter stability and transient response. The first step is to calculate the pole and the right half-plane zero of the peak-current-mode boost converter by Equation 39 and Equation 40. To make the loop stable, the loop must have sufficient phase margin at the crossover frequency less than 1/5 of $f_{(ZRHP)}$.

$$f_{(p)} = \frac{I_{(OUT)}}{2\pi \times V_{(OUT)} \times C_{(OUT)}} = \frac{1}{2\pi \times R_{(OUT)} \times C_{(OUT)}}$$

where

• C_(OUT) is the bulk output capacitance calculated previously

$$f_{(ZRHP)} = \frac{V_{(OUT)} \times (1-D)^{2}}{2\pi \times L \times I_{(OUT)}}$$

$$R_{(OUT)} = \frac{\left(R_{(LED)} + R_{(SENSE)}\right) \times V_{(LED)}}{\left(R_{(LED)} + R_{(SENSE)}\right) \times I_{(LED)} + V_{(LED)}}$$
(40)

R_(LED) is the dynamic impedance of the LED string in ohms at the operating current (41)

The loop compensation consists of a series resistor and capacitor ($R_{(COMP)}$ and $C_{(COMP)}$) from COMP to SGND. $R_{(COMP)}$ sets the crossover frequency and $C_{(COMP)}$ sets the zero frequency of the integrator. For optimum performance, use the following equations:

$$g_{M(COMP)} = 1000$$

$$R_{(COMP)} = \frac{f_{(ZRHP)} \times R_{(ISNSx)}}{f_{(ZRHP)} \times R_{(ISNSx)}}$$
(42)

$$C_{(COMP)} = \frac{1}{5 \times f_{(p)} \times (1 - D_{(MAX)}) \times R_{(SENSE)} \times 5 \times GM_{(COMP)}}$$
(43)
$$C_{(COMP)} = \frac{1}{2\pi \times R_{(COMP)} \times 5 \times f_{(p)}}$$

where

 $f_{(p)}$ is the pole frequency of the power stage calculated by Equation 39 (44)

An output capacitor that is an electrolytic capacitor which has large ESR requires a capacitor to cancel the zero of the output capacitor. Equation 45 calculates the value of this capacitor.

$$C_{6} = \frac{C_{(OUT)} \times R_{(ESR)}}{R_{(COMP)}}$$
(45)

8.2.1.3 Application Curves

8.2.2 Boost-to-Battery Regulator

When the LED forward voltage is between 9 V and 16 V, an appropriate selection is boost-to-battery topology, which can share the same layout and components as the boost topology, with just a different way to connect load.

Figure 22. Boost-to-Battery Regulator Simplified Schematic

TPS92601-Q1, TPS92602-Q1 SLUSBP5E – MARCH 2014 – REVISED JULY 2018

www.ti.com

Figure 23. Boost-to-Battery Regulator Detailed Schematic

8.2.2.1 Design Requirements

For this boost-to-battery regulator example, use the following as the design parameters.

Table 2. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
Input voltage range	Connect to battery (6 V to 16 V)
Output current per channel (I _(setting))	1 A
Output voltage	13.2 V (4 white LEDs)
Input ripple voltage	400 mV
Output ripple current	±10%
Operating frequency	600 kHz

8.2.2.2 Detailed Design Procedure

To begin the design process, one must decide on a few parameters. The designer must know the following:

- Input voltage range
- Output current per channel
- Output voltage
- Input ripple voltage
- Output ripple current
- Operating frequency

Copyright © 2014–2018, Texas Instruments Incorporated

8.2.2.2.1 Switching Frequency

(46)

(47)

(49)

The RT pin resistor sets the switching frequency of the TPS92602y-Q1 device to 600 kHz. Use Equation 2 to calculate the required value for R17. The calculated value is 20.83 k Ω . Use the nearest standard value of 20 k Ω .

8.2.2.2.2 Maximum Output-Current Set Point

The output constant of the TPS92602y-Q1 device is adjustable by using the external current-shunt resistor. In the application circuit of Figure 23, R5 is the channel 1 current-shunt resistor, and R16 is the channel-2 current shunt resistor. Equation 46 and Equation 47 calculate the resistors that determine maximum output current.

 $R_{(\text{sense})} = V_{\text{SPSN}_\text{Diff}} / I_{(\text{setting})}$ R5 = R16 = 150 mV / 1 A = 0.15 Ω

8.2.2.2.3 Output Overvoltage-Protection Set Point

The output overvoltage protection threshold of the TPS92602y-Q1 device is externally adjustable using a resistor divider network. In the application circuit of Figure 23, this divider network comprises of R1 and R3 for channel1 and R2 and R4 for channel2. The following equation gives the relationship of the overvoltage-protection threshold ($V_{(OVPT)}$) to the resistor divider.

$$R1 / R3 = R2 / R4 = (V_{(OVPT)} - V_{(VFB)}) / V_{(VFB)}$$
(48)

The load is four white LEDs, the forward voltage is about 13.2 V, maximum $V_{(VIN)}$ is 16 V, so the maximum output is 13.2 + 16 = 29.2 V, which is close to 30 V. Allowing 20% margin for overvoltage protection, V(OVPT) is: $V_{(OVPT)} = 30 \times 1.2 = 36$ V. So R1 / R3 = R2 / R4 = (36 - 2.2) / 2.2 = 15.36. Select R3 = R4 = 30 k\Omega; then R1 = R2 = 460 k Ω . Use the nearest standard value of 464 k Ω .

8.2.2.2.4 Duty Cycle Estimation

Estimate the duty cycle of the main switching MOSFET using Equation 49 and Equation 50.

$$D_{(MIN)} \approx \frac{V_{(LED)} + V_{(FD)}}{V_{(LED)} + V_{(MAX)} + V_{(FD)}} = \frac{13.2 \text{ V} + 0.5 \text{ V}}{30 \text{ V} + 16 \text{ V} + 0.5 \text{ V}} = 46.1\%$$

where

D is the duty cycle in these and all following equations

$$D_{(MAX)} \approx \frac{V_{(LED)} + V_{(FD)}}{V_{(LED)} + V_{(MIN)} + V_{(FD)}} = \frac{13.2 \text{ V} + 0.5 \text{ V}}{13.2 \text{ V} + 6 \text{ V} + 0.5 \text{ V}} = 69.5\%$$
(50)

Using an estimated forward drop of 0.5 V for a Schottky rectifier diode, the approximate duty cycle is 46.1% (minimum) to 69.5% (maximum).

8.2.2.2.5 Inductor Selection

The peak-to-peak ripple is limited to 30% of the maximum output current.

$$I_{(Lrip-max)} = 0.3 \times \frac{I_{(OUT-max)}}{1 - D_{(MIN)}} = 0.3 \times \frac{1}{1 - 0.461} = 0.556 \text{ A}$$
(51)

Estimate the minimum inductor size using Equation 52

$$L_{(MIN)} >> \frac{V_{(IN-max)}}{I_{(Lrip-max)}} \times D_{(MIN)} \times \frac{1}{f_{(SW)}} = \frac{16 \text{ V}}{0.571 \text{ A}} \times 0.475 \times \frac{1}{600 \text{ kHz}} = 22.1 \,\mu\text{H}$$
(52)

Select the nearest higher standard inductor value of 22 µH. Estimate the ripple current using Equation 53.

$$I_{(RIPPLE)} \approx \frac{V_{(IN)}}{L} \times D_{(MIN)} \times \frac{1}{f_{(SW)}} = \frac{16 \text{ V}}{22 \text{ }\mu\text{H}} \times 0.461 \times \frac{1}{600 \text{ kHz}} = 0.559 \text{ A}$$
(53)

$$I_{(\text{RIPPLE-Vinmin})} \approx \frac{V_{(\text{IN})}}{L} \times D_{(\text{MIN})} \times \frac{1}{f_{(\text{SW})}} = \frac{6 \text{ V}}{22 \ \mu\text{H}} \times 0.695 \times \frac{1}{600 \ \text{kHz}} = 0.316 \text{ A}$$
(54)

The worst-case peak-to-peak ripple current occurs at 46.1% duty cycle and is estimated as 0.559 A. Equation 55 estimates the worst-case rms current through the inductor.

Copyright © 2014–2018, Texas Instruments Incorporated

TEXAS INSTRUMENTS

TPS92601-Q1, TPS92602-Q1 SLUSBP5E – MARCH 2014 – REVISED JULY 2018

www.ti.com

(55)

$$I_{(Lrms)} = \sqrt{(I_{(L-avg)})^2 + \left(\left[\frac{1}{12} \times I_{(RIPPLE)}\right]\right)^2} \approx \sqrt{\left(\frac{I_{(OUT-max)}}{1 - D_{(MAX)}}\right)^2 + \left(\frac{1}{12} \times I_{(RIPPLE-Vinmin)}\right)^2}$$
$$= \sqrt{\left(\frac{1A}{1 - 0.695}\right) + \left(\frac{1}{12} \times 0.3316 \text{ A}\right)^2} = 3.28 \text{ A rms}$$

The worst-case rms inductor current is 3.28 A rms. Equation 56 estimates the peak inductor current.

$$I_{(Lpeak)} \approx \frac{I_{(OUT-max)}}{1 - D_{(MAX)}} + \frac{1}{2} \times I_{(RIPPLE-Vinmin)} = \frac{1}{1 - 0.695} + 0.5 \times 0.316 = 3.44 \text{ A}$$
(56)

Select a 22- μ H inductor with a minimum rms current rating of 3.44 A and minimum saturation current rating of 3.44 A. The selection is a Wurth 7447709220 inductor (shielded-drum core, ferrite, 22 μ H, 5.3 A, 0.0233 Ω , SMD).

Equation 57 estimates the power dissipation of this inductor

$$\mathsf{P}_{(\mathsf{L})} \approx (\mathsf{I}_{(\mathsf{Lrms})})^2 \times \mathsf{DCR}$$
(57)

The Wurth 7447709220 inductor with 23.3-m Ω DCR dissipates 251 mW of power.

8.2.2.2.6 Rectifier Diode Selection

The circuit uses a low-forward-voltage-drop Schottky diode as a rectifier diode to reduce power dissipation and improve efficiency. Use 80% derating for the diode on VOUTx to allow for ringing on the switch node. Equation 58 gives the rectifier-diode minimum reverse-breakdown voltage.

$$V_{(BR)(R-min)} \ge \frac{V_{(VOPT)}}{0.8} = 1.25 \times 36 \text{ V} = 45 \text{ V}$$
 (58)

The diode must have a reverse-breakdown voltage greater than 45 V. Equation 59 and Equation 60 estimate the rectifier diode peak and average currents.

$$I_{(D-avg)} \approx I_{(OUT-max)} = 1 A$$

$$I_{(D-peak)} = I_{(L-peak)} = 3.44 A$$
(60)

For this design, average current is 1 A and peak current is 3.44 A.

Equation 61 estimates the power dissipation in the diode.

$$P_{(D-max)} \approx V_{(F)} \times I_{(OUT-max)} = 0.5 \text{ V} \times 1 \text{ A} = 0.5 \text{ W}$$
 (61)

For this design, the maximum power dissipation is estimated as 0.5 W. After reviewing 45-V and 60-V Schottky diodes, the selection is the 30BQ060PbF diode, Schottky, 60 V, 3 A, SMC. This diode has a forward voltage drop of 0.5 V at 1 A, so the conduction power dissipation is approximately 500 mW, less than half its rated power dissipation.

8.2.2.2.7 Output Capacitor Selection

Assume a maximum LED current ripple of 0.1 × $I_{(LED)}$. Also, assume that the dynamic impedance of the chosen LED is 0.2 Ω (0.8 Ω total for the four-LED string). The total output voltage ripple calculation is then as per Equation 62.

$$V_{(VOUT-ripple)} = 0.1 \text{ A} \times 0.8 \ \Omega = 80 \text{ mV}$$
(62)

Assuming a ripple contribution of 95% from bulk capacitance, Equation 64 calculates the output capacitor.

$$C_{(OUT)} = \frac{I_{(OUT)} \times D}{V_{(VOUT\text{-ripple})} \times 0.95} \times \frac{1}{f_{(SW)}} = \left(\frac{1 \text{ A} \times 0.695}{80 \text{ mV} \times 0.95}\right) \times \frac{1}{600 \text{ kHz}} = 15.2 \text{ }\mu\text{F}$$
(63)

$$\mathsf{ESR} = \frac{\mathsf{V}_{(\mathsf{VOUT-ripple})}}{\mathsf{I}_{(\mathsf{L-peak})}} = \frac{4 \text{ mV}}{3.44 \text{ A}} = 1.16 \text{ m}\Omega$$
(64)

Use five $3.3-\mu$ F capacitors in parallel to achieve the minimum output capacitance of 15.2 μ F. Ensure that the chosen capacitors meet the minimum bulk capacitance requirement at the operating voltage.

8.2.2.2.8 Input Capacitor Selection

Because a boost converter has continuous input current, the input capacitor senses only the inductor ripple current. The input capacitor value can be calculated by Equation 65 and Equation 66.

$$C_{(IN)} = \frac{I_{(L-RIPPLE)}}{4 \times v_{(IN-RIPPLE)} \times f_{(SW)}} = \frac{0.559 \text{ A}}{4 \times 60 \text{ mV} \times 600 \text{ kHz}} = 3.89 \text{ }\mu\text{F}$$

$$ESR = \frac{V_{(VIN-RIPPLE)}}{I_{(L-RIPPLE)}} = \frac{60 \text{ mV}}{2 \times 0.559 \text{ A}} = 53.67 \text{ }m\Omega$$
(65)
(65)

For this design, to meet a maximum input ripple of 60 mV requires a minimum 4- μ F input capacitor with ESR less than 52 m Ω . Select a 10- μ F X7R ceramic capacitor.

8.2.2.2.9 Current Sense and Current Limit

The maximum allowable current sense resistor value is limited by R(ISNSx). Equation 67 gives this limitation.

$$\mathsf{R}_{(\mathsf{ISNSx})} = \frac{\mathsf{V}_{(\mathsf{SNS})}}{1.3 \times \mathsf{I}_{(\mathsf{L}\text{-peak})}} = \frac{100 \text{ mV}}{1.3 \times 3.44 \text{ A}} = 22.36 \text{ m}\Omega$$
(67)

Select a 20-m Ω resistor.

8.2.2.2.10 Switching MOSFET Selection

The TPS92602y-Q1 device drives a ground-referenced N-channel FET. The breakdown voltage is the output voltage plus any voltage spike, with 30% added for a safety margin as shown in Equation 68.

$$V_{(BD-MOS-min)} \ge V_{(VOPT)} \times 1.3 = 1.3 \times 36 \text{ V} = 46.8 \text{ V}$$
 (68)

Select an N-channel FET with breakdown voltage of 50 V.

Estimate the r_{DS(on)} and gate charge based on the desired efficiency target.

$$P_{(DISS-total)} \approx P_{(OUT)} \times \left(\frac{1}{\eta} - 1\right) = 13.2 \text{ V} \times 1 \text{ A} \times \left(\frac{1}{0.92} - 1\right) = 1.148 \text{ W}$$

(69)

For a target of 92% efficiency with a 16-V input voltage at 1 A, maximum power dissipation is limited to 1.148 W. The main power-dissipating devices are the MOSFET, inductor, diode, current-sense resistor and the integrated circuit, the TPS92602y-Q1 device.

$$P_{(FET)} < P_{(DISS-total)} - P_{(L)} - P_{(D)} - P_{(RSNS)} - V_{(IN-max)} \times I_{(VDD)}$$

$$(70)$$

This assumption leaves 600 mW of power dissipation for the MOSFET. Allowing half for conduction and half for switching losses, we can determine a target $r_{DS(on)}$ and $Q_{(GS)}$ for the MOSFET by Equation 71 and Equation 72.

$$Q_{(GS)} < \frac{3 \times P_{(FET)} \times I_{(DRIVE)}}{2 \times V_{(OUT)} \times I_{(OUT)} \times f_{(SW)}} = \frac{3 \times 0.4 \text{ W} \times 0.7 \text{ A}}{2 \times 13.2 \text{ V} \times 1 \text{ A} \times 600 \text{ kHz}} = 28.3 \text{ nC}$$
(71)

Calculate a target MOSFET gate-to-source charge of less than 28.3 nC to limit the switching losses to less than 200 mW.

$$r_{DS(on)} < \frac{P_{(FET)}}{2 \times (I_{(RMS)})^2 \times D} = \frac{0.4 \text{ W}}{2 \times (3.28 \text{ A})^2 \times 0.695} = 26.7 \text{ m}\Omega$$
(72)

Selecting a target MOSFET $r_{DS(on)}$ of 26.7 m Ω limits the conduction losses to less than 250 mW.

TPS92601-Q1, TPS92602-Q1

SLUSBP5E - MARCH 2014 - REVISED JULY 2018

8.2.2.2.11 Loop Compensation

The COMP pin on the TPS92602y-Q1 device is for external compensation, allowing optimization of the loop response for each application. The COMP pin is the output of the internal transconductance amplifier. The external resistor R7, along with ceramic capacitors C5 and C6 (see Figure 23), connect to the COMP pin to provide poles and zero. The poles and zero, along with the inherent pole and zero in a peak-current-mode control boost converter, determine the closed-loop frequency response. This is important to converter stability and transient response. The first step is to calculate the pole and the right half-plane zero of the peak-current-mode boost converter by Equation 73 and Equation 74. To make the loop stable, the loop must have sufficient phase margin at the crossover frequency where the loop gain is 1. To avoid the effect of the right half-plane zero on the loop stability, choose the crossover frequency less than 1/5 of $f_{(ZRHP)}$.

$$f_{(p)} = \frac{I_{(OUT)}}{2\pi \times V_{(OUT)} \times C_{(OUT)}} = \frac{1}{2\pi \times R_{(OUT)} \times C_{(OUT)}}$$

where

• C_(OUT) is the bulk output capacitance previously calculated

$$f_{(ZRHP)} = \frac{V_{(OUT)} \times (1-D)^{2}}{2\pi \times L \times I_{(OUT)}}$$

$$R_{(OUT)} = \frac{\left(R_{(LED)} + R_{(SENSE)}\right) \times V_{(LED)}}{\left(R_{(LED)} + R_{(SENSE)}\right) \times I_{(LED)} + V_{(LED)}}$$
(74)

where

R_(LED) is the dynamic impedance of the LED string in ohms at the operating current (75)

The loop compensation consists of a series resistor and capacitor ($R_{(COMP)}$ and $C_{(COMP)}$) from COMP to SGND. $R_{(COMP)}$ sets the crossover frequency and $C_{(COMP)}$ sets the zero frequency of the integrator. For optimum performance, use the following equations:

$$g_{M(COMP)} = 1000$$

$$R_{(COMP)} = \frac{f_{(ZRHP)} \times R_{(ISNSx)}}{5 - (1 - D) - D - (1 - D) - D - (1 - D)}$$
(76)

$$C_{(COMP)} = \frac{5 \times f_{(p)} \times (1 - D_{(MAX)}) \times R_{(SENSE)} \times 5 \times GM_{(COMP)}}{2\pi \times R_{(COMP)} \times 5 \times f_{(p)}}$$
(77)

where

 $f_{(p)}$ is the pole frequency of the power stage calculated by Equation 73 (78)

An output capacitor that is an electrolytic capacitor which has large ESR requires a capacitor to cancel the zero of the output capacitor. Equation 79 calculates the value of this capacitor.

$$C_{6} = \frac{C_{(OUT)} \times R_{(ESR)}}{R_{(COMP)}}$$
(79)

8.2.2.3 TPS92602y-Q1 Application Curves

9 Power Supply Recommendations

The design of the devices is for operation via direct connection to a battery, so the input-voltage supply range is from 4 V to 40 V. This input supply should be well regulated. If the input supply is located more than a few inches from the TPS9260xy-Q1 family of devices, additional bulk capacitance may be required in addition to the ceramic bypass capacitors.

10 Layout

10.1 Layout Guidelines

- The performance of any switching regulator depends as much on the layout of the PCB as the component selection. Following a few simple guidelines maximizes noise rejection and minimizes the generation of EMI within the circuit.
- Discontinuous currents are the most likely to generate EMI, therefore care should be taken when routing the following paths. The main path for discontinuous current in the TPS9260xy-Q1 buck regulator contains the input capacitor (C_{IN1}), the recirculating diode (D1), the N-channel MOSFET (Q1), and the sense resistor (R_{LIM1}). In the TPS9260xy-Q1 boost regulator, the discontinuous current flows through the output capacitor (C_{O1}), D1, Q1, and R_{LIM1}. In the buck-boost regulator, both loops are discontinuous and require careful attention to layout. Keep these loops as small as possible and the connections between all the components short and thick to minimize parasitic inductance. In particular, make the switch node (where L1, D1 and Q1 connect) just large enough to connect the components. To minimize excessive heating, place large copper pours adjacent to the short current path of the switch node.
- The RT, COMP, ISNS, ICTRL, OVFB, ISP, and ISN pins are all high-impedance inputs which couple external
 noise easily; therefore, minimize the loops containing these nodes whenever possible. In some applications,
 the LED or LED array can be far away (several inches or more) from the TPS9260xy-Q1 family of devices, or
 on a separate PCB connected by a wiring harness. When using an output capacitor where the LED array is
 large or separated from the rest of the regulator, place the output capacitor close to the LEDs to reduce the
 effects of parasitic inductance on the ac impedance of the capacitor.
- AGND and PGND must be separated and connected at the input GND connector.
- The TPS9260xy-Q1 family of devices has two independent channels. in order to avoid crosstalk, the POWER GND of CH1 and CH2 must be separated and connected at the input GND connector.

PowerPAD is a trademark of Texas Instruments. All other trademarks are the property of their respective owners.

11.3 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage. ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more

susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

⁽¹⁾ Status: For more details on status, see our product life cycle.

(2) Material type: When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ RoHS values: Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

⁽⁴⁾ Lead finish/Ball material: Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ MSL rating/Peak reflow: The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ Part marking: There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

PACKAGE OUTLINE

PowerPAD[™] TSSOP - 1.2 mm max height

SMALL OUTLINE PACKAGE

NOTES:

PowerPAD is a trademark of Texas Instruments.

- 1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M. 2. This drawing is subject to change without notice. 3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not

- exceed 0.15 mm per side. 4. Reference JEDEC registration MO-153.
- 5. Features may differ or may not be present.

EXAMPLE BOARD LAYOUT

PowerPAD[™] TSSOP - 1.2 mm max height

SMALL OUTLINE PACKAGE

NOTES: (continued)

- 6. Publication IPC-7351 may have alternate designs.
- 7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
- 8. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature numbers SLMA002 (www.ti.com/lit/slma002) and SLMA004 (www.ti.com/lit/slma004).
- 9. Size of metal pad may vary due to creepage requirement.
- 10. Vias are optional depending on application, refer to device data sheet. It is recommended that vias under paste be filled, plugged or tented.

THERMAL INFORMATION

This PowerPAD[™] package incorporates an exposed thermal pad that is designed to be attached to a printed circuit board (PCB). The thermal pad must be soldered directly to the PCB. After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For additional information on the PowerPAD package and how to take advantage of its heat dissipating abilities, refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 and Application Brief, PowerPAD Made Easy, Texas Instruments Literature No. SLMA004. Both documents are available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

A Exposed tie strap features may not be present.

PowerPAD is a trademark of Texas Instruments

PowerPAD[™] PLASTIC SMALL OUTLINE

NOTES:

A.

- All linear dimensions are in millimeters. This drawing is subject to change without notice. Β.
- Customers should place a note on the circuit board fabrication drawing not to alter the center solder mask defined pad. C.
- This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad D. Thermally Enhanced Package, Texas Instruments Literature No. SLMA002, SLMA004, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <http://www.ti.com>. Publication IPC-7351 is recommended for alternate designs.
- E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.
- F. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.
